REPORT COLLECTIONS IN THE UNITED STATES

The libraries listed below purchase and maintain microfiche collections of USAEC and foreign reports that are abstracted in *NSA*. Their collections also include *NSA* and its indexes, AEC's Technical Progress Reviews, AEC-sponsored translations, conference proceedings published by AEC, and various bibliographic tools. Most of these libraries have microfiche reader-printers or other photocopy facilities with which to reproduce enlarged copies from microfiche. Charges for reproduction services vary.

NSA Vol. 25, No. 16, Replace abstracts 37686, 37687, and 37688 with the following abstracts:

37686 APPARATUS TO DETERMINE THE OPTICAL PROPERTIES IN THE EXTREME ULTRAVIOLET OF FILMS WHICH ARE EVAPORATED AND STORED IN ULTRA HIGH VACUUM (10^{-10} TORR). Daude, A.; Robin, S. (Univ., Rennes, France). Nouv. Rev. Opt. Appl.; 2: No. 1, 57-62(Jan-Feb 1971). (In French).

The optical properties of thin films depend chiefly upon the surrounding conditions of preparation and conservation. An apparatus permitting the determination of optical constants of materials evaporated in ultra high vacuum is described, a device of stockpiling and displacement of the samples allows to conserve and study 40 samples without exposing to air the different chambers. The thicknesses were measured during the evaporation by means of a piezoelectric quartz, the composition of the residual atmosphere being controlled by a quadrupolar gas analyser. Since no window is used between the source and the reflector, the apparatus can be used for any spectral region but principally it is realized for far ultraviolet. The receptor used at present is a Bendix M 306 photomultiplier without any window. The apparatus enables the measurement of transmittance and reflectance for the angles of incidence varying between 15 and 70° with a good precision. Some results of the measurements carried out with this apparatus for Al, Mg, and MgF_2 are given. (auth) (France)

37687 NEW TECHNIQUE FOR NEUTRON DIFFRACTION. USE OF WHITE RADIATION. Hubbard, C. R.; Quicksall, C. O.; Jacobson, R. A. (Ames Lab., Iowa). Nucl. Instrum. Methods; 94: No. 1, 185-6(1971).

A new diffraction method has been developed which uses a white neutron beam. With this method the efficiency of data collection is enhanced approximately one hundred fold. (auth)

37688 WEAPONS EFFECT DISPLAY SYSTEM. Berndt, Carl W.; Reinecker, Frederick Jr.; Downing, Willis G. Jr. (to United States Atomic Energy Commission). U. S. Patent 3,558,865. 26 Jan 1971. Filed 31 Mar 1967.

A system for displaying simulated post-detonation "effects" of a nuclear device on a geographical map is described. The system comprises a geographical plotter and a multiplicity of analog computers for storing the functional relationships between yield characteristics of a nuclear device, manner of detonation, and environmental conditions on one hand, and the "effects" resulting from detonation on the other. In response to input signal data corresponding to the variables of these functional relationships, the analog computers issue output signals representative of the associated magnitudes and ranges of the "effects" and such range signals are simultaneously utilized to project and superimpose figures onto a geographical map by means of the plotter. The area on the map encompassed by each figure indicates the geographical extent subjected to the corresponding simulated nuclear detonation "effect." (auth)

NUCLEAR SCIENCE ABSTRACTS

A semimonthly publication of the USAEC Division of Technical Information, Edward J. Brunenkant, Director,
Published by the USAEC Division of Technical Information Extension, Robert L. Shannon, Extension Manager.

Nuclear Science Abstracts provides the only comprehensive abstracting and indexing coverage of international nuclear science literature. *Nuclear Science Abstracts* covers scientific and technical reports of the U. S. Atomic Energy Commission and its contractors, other U. S. Government agencies, other governments, universities, and industrial and research organizations. In addition, books, conference proceedings, individual conference papers, patents, and journal literature on a worldwide basis are abstracted and indexed. Each issue of *Nuclear Science Abstracts* includes four indexes: subject, personal author, corporate author, and report number.

The following organizations scan and abstract the nuclear science literature in their respective countries:

Atomic Energy of Canada Limited
Australian Atomic Energy Commission
Danish Atomic Energy Commission
Finnish Atomic Energy Commission
French Atomic Energy Commission
Japan Atomic Energy Bureau–Atomic Energy Research Institute
Institutt for Atomenergi (Norway)
Aktiebolaget Atomenergi (Sweden)
United Kingdom Atomic Energy Authority

Numerous organizations, societies, and publishers throughout the world provide *Nuclear Science Abstracts* with advance page-proof copy of their publications, e.g., in the United States the American Institute of Physics provides page-proof copy of its publications.

A list of the journals scanned regularly and the abbreviations used appears in Issue 1 (January 15) of each volume of *Nuclear Science Abstracts* and is supplemented in Issues 7, 13, and 19. Issue 1 of each volume also describes the scope and arrangement of the subject matter covered in *Nuclear Science Abstracts.* The subject matter covered is also described in TID-4552, *Subject Scope of Nuclear Science Abstracts,* available free from the USAEC Division of Technical Information Extension, P.O. Box 62, Oak Ridge, Tennessee 37830. An outline of the subject categories appears in the Contents of each issue.

AVAILABILITY OF PUBLICATIONS ABSTRACTED

Public availability of all U. S. Atomic Energy Commission reports is indicated in the report number indexes. The availability of other reports, when known, is also indicated. The availability of some unnumbered reports is given in the abstract.

Dissertations abstracted in *Dissertation Abstracts* and included in *Nuclear Science Abstracts* are available from University Microfilms, Inc., 315 N. First Street, Ann Arbor, Michigan 48103.

Information on the availability of the published literature and unpublished conference papers abstracted in *Nuclear Science Abstracts* can be obtained from the USAEC Division of Technical Information Extension, P.O. Box 62, Oak Ridge, Tennessee 37830.

HOW TO OBTAIN NUCLEAR SCIENCE ABSTRACTS

Nuclear Science Abstracts is available to the public on a subscription basis from the Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402.

For the 24 regular issues, the yearly rate is $42.00 for domestic subscribers and $52.50 for foreign subscribers. A single issue costs $1.75, domestic rates, or $2.19, foreign rates. Domestic rates apply to the United States, Canada, Mexico, and Central and South American countries except Argentina, Brazil, Guyana, French Guiana, Surinam, and British Honduras.

For a yearly subscription to the cumulative indexes, the rates are $34.50 for domestic subscribers and $43.00 for foreign subscribers.

The following cumulative indexes are available:

From Johnson Reprint Corporation, 111 Fifth Avenue, New York, N. Y. 10003:
Vols. 1–4, Subjects and Authors (1948–1950), $30.00.

From Superintendent of Documents, U. S. Government Printing Office, Washington, D. C. 20402:

Vols. 5–10, Subjects and Authors (1951–1956), $5.25.

Vols. 11–15, Subjects (1957–1961), $19.00.
Vols. 11–15, Personal Authors (1957–1961), $14.25.
Vols. 11–15, Corporate Authors (1957–1961), $2.50.

Vols. 16–20, Subjects (1962–1966), $36.00.
Vols. 16–20, Personal Authors (1962–1966), $22.50.
Vols. 16–20, Corporate Authors (1962–1966), $3.75.

Vol. 21, Subjects and Authors (1967), $16.00.
Vol. 22, Subjects and Authors (1968), $26.00.
Vol. 23, Subjects and Authors (1969), $25.75.
Vol. 24, Subjects and Authors (1970), $22.50.
Vol. 24, Authors (1970), Suppl., $2.00.

Cumulative Report Number Index, Vols. 1–15 Revised, $4.00.
Cumulative Report Number Index, Vols. 16–20 Revised, $5.50.
Cumulative Report Number Index, Vols. 21–24, $4.25.

Nuclear Science Abstracts is available on an exchange basis to universities, research institutions, industrial firms, and publishers of scientific information. Government agencies may obtain *NSA* free of charge. Inquiries should be directed to the USAEC Division of Technical Information Extension, P. O. Box 62, Oak Ridge, Tennessee 37830.

XUM

Nuclear Science Abstracts is also available on 16-mm microfilm in open reels or cartridges from Princeton Microfilm Corporation, Alexander Road, Princeton, New Jersey 08540. The backfile, which includes *Abstracts of Declassified Documents* (1947–1948), *Nuclear Science Abstracts* (1948–1969), *Nuclear Science Abstracts* cumulative indexes (1948–1966), and *Nuclear Science Abstracts* annual indexes (1967–1969), is $975. Yearly backfiles, beginning with 1970, and subscriptions, including cumulative indexes, are $125 per year.

INDEXES TO NSA

Comprehensive indexes appear in each issue and are cumulated quarterly and annually. Multivolume cumulations have been issued as indicated above.

All documents abstracted are indexed by subjects and personal authors. Report literature is indexed also by corporate author and report number. Each of these indexes in every issue is preceded by an introduction explaining in detail the organization of the index and the principles by which it is compiled. The reader is referred to these explanations for information not found in the brief summary below.

Personal Authors

Each author's name is indexed in the form appearing on the document abstracted:

NEWCOMB, William A., Stability of a magnetic well, 25:1239
NEWKIRK, L. R., Superconductivity in the pseudobinary alloys V_3Si--Nb_3Al, 25:1093 (CALT-822-13)
NEWLAND, E. A., Radiation treatment of sewage, 25:140 (AAEC/LIB/Bib-254)

Subjects

The subject index consisting of specific materials, objects, and processes is arranged alphabetically. Modifying phrases specific to these subjects in turn are arranged alphabetically under the subjects.

TRANSURANIUM ELEMENTS
determination in bone ash, radiochemical method for, 25:40 (IDO-12073, pp 28-36)
separation by ion exchange and complex-formation elution, 25:251(P)

TRIETHYLENETETRAMINE
complexes with cobalt(III) and rhodium(III) chlorides, radiation effects on labeled, thermal-neutron, 25:137

TRITIUM
content in Cattaraugus Creek near West Valley Processing Plant, July through Dec. 1969, 25:258 (DOCKET-50201-48)
content in Cattaraugus Creek near West Valley Processing Plant, Jan. to July 1970, 25:259 (DOCKET-50201-49)
determination in luminescent material by scintillation counting, 25:40 (IDO-12073, pp 28-36)

Corporate Authors

Technical report literature is indexed from the name of the organization or institution responsible for the issuance of the report.

372 (UCRL-72739) CONSTRUCTION OF A UNIQUE UNDERGROUND WHOLE BODY COUNTER. Griffith, R. V.; Anderson, A. L.; Lindeken, C. L. **(California Univ., Livermore. Lawrence Radiation Lab.).** Oct 1970. 27p. (CONF-701009-1). Dep. NTIS.

is indexed as:

CALIFORNIA UNIV., LIVERMORE. LAWRENCE RADIATION LAB.
Construction of a unique underground whole body counter, 25:372 (UCRL-72739)

Report Numbers

Technical report literature is also indexed by report numbers. This index includes information on where individual reports may be obtained. While not reports, patents and conference papers are indexed here as a matter of convenience.

57297 (NBS-SPEC. PUBL.-260-30) STANDARD REFERENCE MATERIALS: STANDARD SAMPLES ISSUED IN THE USSR. Gorozhanina, R. S.; Freedman, A. Y.; Shaievitch, A. B. Translated by M. C. Selby (National Bureau of Standards, Boulder, Colo.), from the Russian. 82p. GPO $1.00.

Information is presented on standard samples of properties and composition of substances and materials including areas of their application, nomenclature, certified characteristics, and values of the certified quantities. (auth)

57298 (ORNL-4676, pp 73-138) CHEMISTRY. (Oak Ridge National Lab., Tenn.). Aug 1971.

In Molten-Salt Reactor Program semiannual progress report for period ending February 28, 1971.

BERYLLIUM FLUORIDES—BeF_2-LiF, thermodynamic properties of molten
 —BeF_2-NaF, phase transitions in molten
 —spectra in molten fluorides, Raman
BORON FLUORIDES—solubility of gaseous, in fluoride melts
CESIUM—separation from MSBR fuel solvent by reductive extraction
CESIUM URANIUM FLUORIDES—crystal structure
FUSED SALTS—sound velocity in, effects of entropy on
HELIUM—solubility in molten lithium beryllium fluorides
HYDROGEN—determination in MSRE pump bowl gas
 —diffusion through oxide-coated metals
 —solubility in molten lithium beryllium fluorides
INCONEL—corrosion by molten sodium fluoride–sodium fluoroborate solution
LITHIUM BERYLLIUM FLUORIDES—reactions of molybdenum or niobium fluorides in molten, kinetics of
 —solvent properties of molten, for helium and hydrogen
LITHIUM FLUORIDES—BeF_2-LiF, solvent properties of molten, for gaseous boron trifluoride
 —$BeF_2-LiF-ThF_4$, separation of cesium and rubidium from, by reductive extraction
LITHIUM MOLYBDENUM FLUORIDES—crystal structure
METALS—diffusion of hydrogen through oxide-coated
MOLTEN SALT BREEDER REACTOR—fuel reprocessing for
MOLTEN SALT REACTOR EXPERIMENT—fission product chemistry in
 —fuel pump bowl in, examination of deposits from mist shield in
MOLYBDENUM FLUORIDES—reactions in molten lithium beryllium fluoride solutions, kinetics of
NIOBIUM FLUORIDES—disproportionation of NbF_4
 —reactions in molten lithium beryllium fluoride solutions, kinetics of
 —mass spectra of
POTASSIUM THORIUM FLUORIDES—crystal structure
PROTACTINIUM—redox potential of, in MSBR fuel solvent salt
RARE EARTHS—separation from MSBR fuel by extraction
REACTOR FUELS—chemistry of molten salt
RUBIDIUM—separation from MSBR fuel solvent by reductive extraction
RUBIDIUM FLUOROBORATES—$RbBF_4-RbF$, phase diagram of
RUBIDIUM THORIUM FLUORIDES—crystal structure
RUBIDIUM ZIRCONIUM FLUORIDES—crystal structure
SODIUM FLUORIDES—$NaBF_4-NaF$, reactions of molten, with water
 —$NaBF_4-NaF$, corrosive effects of molten, on Inconel
 —analysis of molten, for hydrogen- and deuterium-containing impurities, spectroscopic
 —BeF_2-NaF, electric conductivity of molten and supercooled
SODIUM FLUOROBORATES—analysis of molten, for hydrogen- and deuterium-containing impurities, spectroscopic
 —spectra of polycrystalline, Raman
TRITIUM—determination in MSRE pump bowl gas
 —exchange with bound hydrogen in fluoroborate coolants
URANIUM FLUORIDES UF_4—enthalpy at 298 to 1400°K
URANIUM FLUORIDES UF_5—disproportionation equilibrium of solutions of (M.C.G.)

57299 THIN-LAYER ELECTROPHORESIS IN INORGANIC ANALYSIS. COMMUNICATION I. SEPARATION OF CERTAIN RARE EARTHS IN COMPLEXONE III SOLUTIONS. Makarova, T. P.; Stepanov, A. V. Zh. Anal. Khim.; 26: No. 9, 1823-5(Sep 1971). (In Russian).

The separation of microamounts of certain rare earths (Ce, Pm, Eu) in a Complexon III solution can be carried out by low-voltage thin-layer ionophoresis on silica gel and cellulose under conditions similar to those in the method of electromigration on paper. The results of the separation of elements depend on the peculiarities of various sorbents. Cellulose powders are more effective than silica gel. (auth)

Chemical and Spectral Procedures

57300 (ORO-3847-2) STUDY OF PARTICULATE HETEROGENEITY EFFECTS IN RADIOISOTOPE X-RAY SPECTROMETRY. Berry, P. F. (Nuclear-Chicago Corp., Austin, Tex. Texas Nuclear Div.). 3 Jun 1971. Contract AT(40-1)-3847. 107p. Dep. NTIS.

Theories of particle size effects on x-ray interaction phenomena are reviewed and a new model which provides experimentally consistent formulas for x-ray fluorescence, transmission, and back-scattered radiation intensities in granular materials and slurries is developed. The new model is applicable to homogeneous and dissimilar size particle mixtures. The applicability of radiometric methods of particle size analysis was investigated for selected matrices. Methods hitherto proposed, such as dual x-ray fluorescence and transmission, were examined in particular with regard to the mutual influences of particle size, chemical composition, and (slurry) solids content. In mixtures of particles of equal size, size determination independent of chemical composition was shown feasible by appropriate choice of x-ray energies. The practicality of these techniques, however, appears questionable for dissimilar size particle mixtures. (auth)

57301 (TID-25776) NATURAL CESIUM IN SEA WATER. Folsom, T. R.; Hansen, N. (Scripps Institution of Oceanography, La Jolla, Calif.); Robertson, D. E. (Battelle Pacific Northwest Labs., Richland, Wash.). 18 Aug 1970. 9p. Dep. NTIS.

A method is presented for the determination of cesium in sea-water that involves treating two 1-liter samples together, one having 0.500 μg ^{133}Cs added. The cesium is precipitated by ammonium 12-molybdophosphate (AMP), and extracted into TBP, then burned in a burning cup in a recording differential emission

XUM

photometer. Long storage of seawater samples in polyethylene has little effects (less than 3%) on cesium content. (D.H.M.)

57302 PLATINUM-GRAPHITE ELECTRODE SYSTEM FOR THE BIAMPEROMETRIC DETERMINATION OF IODINE. Prasad, B. B.; Khandelwal, G. D. (Banaras Hindu Univ., India). Z. Anal. Chem.; 253: No. 2, 123-4(1971).

An investigation was made of wax-impregnated graphite electrodes in combination with platinum for the biamperometric determination of iodine. Errors of 0.3 to 1% were found. (M.C.G.)

57303 BEHAVIOUR OF HALIDE IONS TOWARDS CHLORAMINE-T IN QUALITATIVE ANALYSIS. Rao, V. R. S. (Indian Inst. of Tech., Madras). Z. Anal. Chem.; 253: No. 2, 128(1971).

The study of behavior of halides towards Chloramine-T was undertaken. Fluoride was inert in all media; chloride was inert at pH 2 to 14, but oxidized and chlorine evolved in strong acid medium. Bromide destroys all Chloramine-T in the pH range 2.65 to 5.0; above pH 5, bromine is not reacted by Chloramine-T. Iodine can be determined in 2 to 4 M HCl medium and bromine can be determined in HCl or H_2SO_4. Iodide is oxidized to iodine in all media from strongly acid to pH 6. (M.C.G.)

57304 HIGHLY SELECTIVE AND RAPID SPECTROPHOTOMETRIC DETERMINATION OF Ca BY EXTRACTION OF THE Ca-GLYOXAL-BIS(2-HYDROXYANIL) COMPLEX WITH A MIXTURE OF 1-OCTANOL AND 2-OCTANOL. Keil, R. (Eidgenoessisches Institut fuer Reaktorforschung, Wuerenlingen, Switzerland). Z. Anal. Chem.; 253: No. 1, 15-19(1971). (In German).

A rapid and simple procedure for the spectrophotometric determination of Ca using glyoxal-bis(2-hydroxyanil) is described. The red colored complex is extracted from an alkaline solution (0.4 to at least 1.5 N NaOH) into an organic phase consisting of 1-octanol and 2-octanol (volume ratio 1:4). After extraction the color of the organic phase is stable for at least 1 hr and can be measured at 545 nm. The selectivity of the method is increased by masking with KCN and by removing of interfering cations with ammonium pyrrolidinedithiocarbamate and phenylarsonic acid, respectively. Larger quantities of Ba and Sr are separated with sodium rhodizonate at pH 4.5. The determination of Ca in the presence of 60 cations and 19 anions was investigated. (auth)

57305 DETERMINATION OF URANIUM CONTENT AND UO_2 STOICHIOMETRY IN ThO_2–UO_2 NUCLEAR FUELS. Neeb, K. H.; Neidl, H. (Siemens AG, Erlangen, Ger.). Z. Anal. Chem.; 253: No. 1, 29-31(1971). (In German).

Analysis for uranium and UO_2 stoichiometry in 2.5 to 5% UO_2-containing ThO_2-UO_2 fuels is made in a single procedure by controlled-potential coulometry. Samples are dissolved in phosphoric acid–hydrofluoric acid with the addition of $Al_2(SO_4)_3$. With sample weights from 0.2 to 2 g the uranium content is determined with a relative standard deviation of 1%. The minimum detectable hyperstoichiometry of UO_3 amounts to 2.004 with a standard deviation of 0.002. (auth)

57306 ATOMIC ABSORPTION SPECTROPHOTOMETRIC DETERMINATION OF MOLYBDENUM IN FERTILIZERS. Koirtyohann, S. R.; Hamilton, Maureen (Univ. of Missouri, Columbia). J. Ass. Offic. Anal. Chem.; 54: No. 4, 787-9(Jul 1971).

Molybdenum is extracted into chloroform from fertilizer sample solutions at pH 1.6 as the 8-hydroxyquinolate. Atomic absorption in the premixed nitrous oxide–acetylene flame is used for determination. Methyl isoamyl ketone is added to the chloroform extract to improve the burning qualities. The method is sensitive and precise but appears to have a positive bias of about 5%. (auth)

57307 POLAROGRAPHIC DETERMINATION OF Cd, Co, Mn, Zn, Te(IV), and Cr(VI) IN SODIUM AZIDE SOLUTION. Rao, A. L. J.; Puri, B. K. (Punjabi Univ., Patiala, India). Z. Anal. Chem.; 254: No. 5, 362-3(1971).

Sodium azide was used as a supporting electrolyte for studying the polarographic characteristics of Cd, Co, Mn, Zn, Te, and Cr at a dropping mercury electrode. The plot of log $i/i_d - i$ versus E gave straight lines in all the cases and the value of the slopes in the cases of Zn, Cd, and Mn indicated that these metals undergo reversible reduction with two-electron change and the value of the slopes in case of Co, Cr, and Te corresponded to an irreversible reduction. (M.C.G.)

57308 GRAVIMETRIC DETERMINATION OF MOLYBDENUM(VI) WITH SALICYLHYDROXAMIC ACID. Chaudhuri, Nirmal K.; Sarkar, Ajit K.; Das, Jyotirmoy (Univ. of Burdwan, Bengal, India). Z. Anal. Chem.; 254: No. 5, 365-6(1971).

This reagent forms an insoluble yellow complex with molybdenum (VI) of the formula $MoO_2(C_7H_6O_3N)_2$, which can be weighed directly. (M.C.G.)

57309 TITRIMETRIC DETERMINATION OF IRON(II), MOLYBDENUM(V), AND THALLIUM(I) WITH POTASSIUM CHLORATE TO A POTENTIOMETRIC END-POINT. Radhakrishnamurty, C.; Gopala Rao, G. (Andhra Univ., Waltair, India). Z. Anal. Chem.; 254: No. 5, 366-7(1971).

The reactions of potassium chlorate are strongly catalyzed by hydrogen ions. Advantage was taken of this fact in developing titrimetric procedures for the determination of iron(II), molybdenum(V), and thallium(I). In these reactions it was observed that potassium chlorate functions as a 6-electron accepting oxidizing agent. (M.C.G.)

57310 STRONTIUM CONCENTRATIONS AND STRONTIUM-CHLORINITY RATIOS IN SEA WATER OF THE NORTH PACIFIC AND THE ADJACENT SEAS OF JAPAN. Nagaya, Yutaka; Nakamura, Kiyoshi; Saiki, Masamichi (National Inst. of Radiological Sciences, Chiba, Japan). Nippon Kaiyo Gakkaishi; 27: No. 1, 20-6(Feb 1971).

Strontium contents of 232 seawater samples collected at various stations in the North Pacific and adjacent seas of Japan were measured by atomic absorption spectrophotometry and strontium: chlorine ratios were determined. The mean Sr concentration was 8.08 mg/kg and mean Sr/Cl ratio was 0.425 mg/kg/‰. Contrary to some recent reports, regional and vertical variations of Sr/Cl ratios were statistically insignificant, and the presence of particulate strontium was not confirmed. (auth) (Japan)

57311 POLAROGRAPHIC DETERMINATION OF Bi, Cu, Pb, Cd, Zn AS IMPURITIES IN RARE EARTH PREPARATIONS. Il'kova, S. B.; Zazimko, E. A. Zh. Anal. Khim.; 26: No. 8, 1660-1(Aug 1971). (In Russian).

Polarographic reduction of Bi, Cu, Pb, and Cd occurs reversibly in the presence of a large (up to 20 to 40 g/liter) excess of the rare earths. The reversibility of zinc reduction in the presence of the rare earths is broken. Methods were developed for determining Bi, Cu, Pd, and Cd in specially pure rare earth oxides with a sensitivity of 2×10^{-5}% and for determining zinc with a sensitivity of 2×10^{-3}% in rare earth oxides and with a sensitivity of 0.01% in europium oxide. The variation coefficients for the determination of 1×10^{-2} to 2×10^{-5}% of elements are within 12 to 21%. (auth)

57312 GROUP CONCENTRATION OF ELEMENTS BY EXTRACTION WITH A HYDROXYQUINOLINE MELT. Lobanov, F. I.; Buyanovskaya, A. G.; Gibalo, I. M. (Moscow State Univ.). Zh. Anal. Khim.; 26: No. 8, 1655-7(Aug 1971). (In Russian).

Group concentration of Cu, Ag, Au, Zn, Al, Ga, Zr, Pb, Sb, Bi, Cr, Mn, Fe, Co, and Ni ions by means of a hydroxyquinoline melt is possible. The method of the group concentration of ions of certain metals is combined with their spectrographic determination. The analysis of sodium hypophosphite for impurities of certain elements was carried out. (auth)

57313 SPECTROGRAPHIC METHOD FOR DETERMINING MAIN COMPONENTS IN ALLOYS BASED ON COBALT. Muzgin, V. N.; Pupyshev, A. A.; Antonov, A. V. (Ural Polytechnic Inst., Sverdlovsk, USSR). Zh. Anal. Khim.; 26: No. 8, 1589-92(Aug 1971). (In Russian).

The possibility was shown of determining main components in cobalt-base alloys by emission spectrography. The accuracy of the method was increased by using a stable excitation source, by feeding the analyzed samples as solutions into the excitation zone, and by using the regularities in changes of the sample composition. Methods were developed for the analysis of samarium–cobalt, praseodymium–cobalt, and samarium–nickel–cobalt alloys for the main components. The mean relative error of the methods is 0.5 to 2.0%. (auth)

57314 POTENTIAL OF A SILVER HALIDE ELECTRODE IN A FLOW UNDER THE CONDITIONS OF COMPLEX FORMATION. POTENTIOMETRIC DETERMINATION OF MICROCONCENTRATIONS OF IODIDE IONS. Bardin, V. V.; Tolstousov, V. N. (Leningrad Technological Inst.). Zh. Anal. Khim.; 26: No. 8, 1580-4(Aug 1971). (In Russian).

Equations were derived for the potential of a silver halide electrode in a laminar flow under the conditions of complex formation when there are either halide or silver ions in the solution. The equations were checked experimentally taking as an example a silver iodide electrode washed by an ammonia supporting electrolyte. In the range of small concentrations of iodide or $Ag(NH_3)_2^+$ ions the potential of the silver iodide electrode is a linear function of the concentration of the above ions. A method is suggested for determining iodide ions and silver with a sensitivity about 10^{-6} g/liter. The determination can be carried out in the presence of large amounts of certain anions which form difficultly soluble silver compounds. The method was used for determining microimpurities of iodides in KCl, KBr, and KIO_3 preparations. (auth)

57315 PHOTOMETRIC DETERMINATION OF NIOBIUM WITH MAGNESON. Elinson, S. V.; Nezhnova, T. I. Zh. Anal. Khim.; 26: No. 8, 1535-9(Aug 1971). (In Russian).

Magneson was studied as a reagent for niobium. A colored complex is formed in a tartrate solution. The absorption maximum of the complex is at the HCl concentration of 1 to 2 N. Niobium reacts with magneson at a molar ratio of 1 : 1, the molar extinction coefficient of the complex is $1.6 \cdot 10^4$, the apparent dissociation constant is $K_{dis} = (3.08 \pm 0.9) \cdot 10^{-28}$. The method with magneson was applied to the determination of niobium in alloys based on copper, iron, and zirconium. (auth)

57316 MIXED COMPLEX COMPOUNDS OF NIOBIUM WITH POLYPHENOLS AND ORGANIC BASES. Gibalo, I. M.; Eremina, G. V. (Moscow State Univ.). Zh. Anal. Khim.; 26: No. 8, 1531-4(Aug 1971). (In Russian).

Mixed complex compounds are formed in 8 to 9 M HCl at concentrations of 10^{-2} M of diantipyrylpropylmethane (DAPPM), 0.1 M of pyrocatechol (PC), and 0.2 M of pyrogallol (PG). These complex compounds Nb–DAPPM–PC and Nb–DAPPM–PG are soluble in 8 to 9 M HCl and can be extracted with organic solvents. The absorption spectra of the chloroform extracts of the Nb–DAPPM–PG compound have the maximum absorption band at 380 to 390 nm, $\epsilon = (14.1 \pm 0.7) \cdot 10^3$, that of the Nb–DAPPM–PC compound is at 390 to 400 nm, $\epsilon = (11.9 \pm 0.5) \cdot 10^3$. The molar ratios Nb : DAPPM : PC(PG) = 1 : 2 : 2 were established by the equilibrium shift method. The extraction of these compounds with organic solvents of various classes was studied. The best solvents are chloroform and benzene. Niobium can be determined in the presence of 20- to 30-fold amounts of titanium and 3- to 5-fold amounts of tantalum. (auth)

57317 USE OF A TERBIUM COMPLEX WITH 1,2-DIHYDROXYBENZENE-3,5-DISULFONIC ACID AS A LUMINESCENT INDICATOR IN THE MICROVOLUMETRIC DETERMINATION OF THE RARE EARTH ELEMENTS. Alakaeva, L. A.; Tishchenko, M. A.; Poluektov, N. S. (Inst. of General and Inorganic Chemistry, Odessa). Zh. Anal. Khim.; 26: No. 8, 1514-16(Aug 1971). (In Russian).

Conditions were found for the complexonometric determination of the rare earth elements using a terbium complex with 1,2-dihydroxybenzene-3,5-disulfonic acid as a luminescent indicator. The luminescence is excited by ultraviolet light from a mercury lamp. Li, K, Na, Cs, Be, Al, Ga, Ge, Mo, Te, UO_2^{2+} ions do not interfere in the determination of the rare earths. The standard deviation of a single determination is 0.13 to 0.22%. (auth)

57318 SPECTROPHOTOMETRIC DETERMINATION OF SMALL AMOUNTS OF SCANDIUM AND YTTRIUM IN EACH OTHERS PRESENCE. Bocharova, R. I.; Kusheleva, A. F.; Men'kov, A. A. (Second Moscow State Medical Inst.). Zh. Anal. Khim.; 26: No. 8, 1505-10(Aug 1971). (In Russian).

A method is suggested for the spectrophotometric determination of small amounts of yttrium with Arsenazo M in the presence of large amounts of scandium using NaH_2PO_4 as a masking agent. (auth)

57319 KINETIC METHOD FOR ANALYZING MIXTURES OF THE RARE EARTH ELEMENTS BASED ON THE DIFFERENCE IN THE RATES OF THE SUBSTITUTION REACTIONS IN THE COMPLEXES WITH POLYDENTATE LIGANDS. Budarin, L. I.; Yatsimirskii, K. B.; Khachatryan, A. G. (Inst. of Physical Chemistry, Kiev). Zh. Anal. Khim.; 26: No. 8, 1499-1504(Aug 1971). (In Russian).

A kinetic method for the quantitative determination of the rare earth elements was developed with the use of the parallel reactions. Two methods for the treatment of the experimental data depending on the ratios of the rate constants of the reactions are proposed. The method was applied to the quantitative determination of praseodymium and ytterbium and also lanthanum and samarium in their mixtures using the parallel reactions of replacement of Xylenol Orange by ethylenediaminetetraacetate in their intensively colored complexes with a suitable reagent. (auth)

57320 CHEMICAL ANALYSIS OF THE FUEL SOLUTION OF JRR-1. Hashitani, Hiroshi; Komori, Takuji; Yamamoto, Tadashi (Japan Atomic Energy Research Inst., Tokai). Nippon Genshiryoku Gakkaishi; 13: No. 6, 335-8(Jun 1971). (In Japanese).

Tests were conducted on the JRR-1 in July 1960, in order to solve a number of problems essential to the operation of the reactor. The state of corrosion of the core tank wall, the behavior of the gas recombiner water, and the state of the fuel solution were examined. Additional tests were carried out in November 1967 and in January 1970. The change in volume of the fuel solution was determined by measurements of the density and the uranium concentration, and the cause of this volume change was clarified. The corrosion products and metals added to the fuel solution, i.e., iron, nickel, chromium, and copper were determined. In the second and third tests, all of the above items, as well as sulfuric acid concentration, plutonium production, and burnup were measured. All the results were compared with the values obtained at the first startup of the reactor. In the third test, a considerable amount of aluminum was found in the gas recombiner water. This element must have originated in the catalyst used in the recombiner. From the burnup determined by mass spectrometry, the cumulative power output was estimated to be nearly 22×10^4 kWh. (auth) (Japan)

57321 POLAROGRAPHIC METHOD OF DETERMINING URANIUM IN THE PRESENCE OF IRON. Tomik, B.; Matous, K. (Inst. of Mining and Metallury, Ostrava, Czech.). Hutn. Listy; 25: No. 8, 581-3(Aug 1970). (In Czech).

Polarographic reduction of uranyl ions was studied in solutions of various carbonates: sodium bicarbonate, sodium carbonate, potassium bicarbonate, potassium carbonate, sodium potassium carbonate, and ammonium carbonate. The polarographic curves differed neither in height nor in shape; slight differences were only observed between individual half-wave potential values. It is thus concluded that in all cases the same complex, $[UO_2(CO_3)_3]^{4-}$, was formed and reduced. In another experiment the reduction was performed in the presence of bicarbonate. Iron and uranium were precipitated with NaOH as $Fe(OH)_3$ and $Na_2U_2O_7$, respectively. An excess of $NaHCO_3$ was added which led to the formation of the soluble uranium complex $Na_4[UO_2(CO_3)_3]$. Polarographic reduction of this complex was studied. The method was tested on steel samples containing uranium additions. The diffusion current was practically independent of $NaHCO_3$ concentration, of pH (between pH = 7.9 and 12.3), and of iron concentration. The polarographic method yielded slightly higher results than the chemical method. Uranium concentration in the analyzed steel samples varied between 0.28 and 14.98%. For this concentration range the proposed polarographic method is quite satisfactory and yields reliable results. (NSA of Czech.)

57322 USE OF ROSS FILTERS IN RADIOISOTOPE X-RAY FLUORESCENCE DETERMINATION OF IODINE IN DRUGS. Svitel, J.; Dohnalova, E. (Komensky Univ., Bratislava). Cesk. Farm.; 19: No. 3, 89-95(Apr 1970). (In Slovak).

The use of differential Ross filters for selection of the characteristic radiation in radioisotope x-ray fluorescence analysis of drugs and chemicals containing iodine was investigated. Metal filters from rolled tin, indium, and cadmium were used. A ^{147}Pm/La bremsstrahlung source was used as the source of exciting radiation. The method was compared with the x-ray fluorescence method using pulse height selection of the characteristic radiation without a filter. The method studied was found to be less sensitive but had some other advantages (possibility of uniform calibration and elimination of the matrix effect, simplicity and low cost, and higher resolution). (NSA of Czech.)

57323 RAPID PHOTOMETRIC DETERMINATION OF SELENIUM IN TELLURIUM WITH DIFFERENT PURITY (UP TO 99.99 PERCENT). Futekov, L.; Atanasova, B. (Higher Pedagogical School, Plovdiv, Bulgaria). Natura (Plovdiv); 3: No. 1, 65-9 (1970).

Se impurities in 99 to 99.99% pure Te were determined photometrically by reducing Se(IV) in 6N HCl with Me_2CO to give a colloidal solution of Se (stabilized with gelatin), the absorbance of which was measured at 550 nm. Beer's law was followed for 50 to 500 μg Se/25 ml. The relative standard deviation was 13.63% for determining 200 μg Se in the presence of 0.6 g Te. (Selenium–Tellurium Abstr.)

57324 DETERMINATION OF SILICON IN PURE TELLURIUM. Dobrowolski, Jan; Kwiatkowska-Sienkiewicz, Krystyna (Politechnika, Danzig). Chem. Anal. (Warsaw); 15: No. 3, 647-50 (1970). (In Polish).

Silicon is determined spectrophotometrically as the molybdosilicate blue after the preliminary removal of Te with tributyl phosphate. The 0.1-g sample is dissolved in 50% HCl–50% HNO_3 (5 : 1). The solution is evaporated, and the residue is dissolved in 15 ml of 8M HCl and extracted with 30% TBP in CCl_4 (2 × 10 ml). The aqueous solution, washed with 10 ml of CCl_4, is evaporated and the residue is fused with 0.2 g of Na_2CO_3. The melt is dissolved in ≃15 ml of H_2O and, after adjusting the pH to 1.5 with N-H_2SO_4, the solution is treated with 10 ml of 5% $(NH_4)_6Mo_7O_{24} \cdot 4H_2O$ solution. After 5 min., 5 ml of 5% citric acid solution and 14.5 ml of H_2SO_4 (1 : 3) are added and the solution is extracted with butanol (2 × 10 ml). The extract is made up to 25 ml with butanol, the complex is reduced with 1 ml of 1% $SnCl_2 \cdot 2H_2O$ solution, and, after 10 min., the extinction of this solution is

XUM

measured at 760 nm against butanol. Residual Te, present at ≈0.8 μg per ml, lowers the extinction reading by 3%, and ≈15% of the Si present is lost during this procedure. The standard deviation for samples containing 0.0228 ± 0.0070% of Si (in 99.8% pure tellurium) is 0.0019%. (Anal. Abstr.)

57325 SPECTROPHOTOMETRIC DETERMINATION OF RUTHENIUM WITH 3,4-DIAMINOBENZOIC ACID. **Ayres, Gilbert H.; Arno, James A. (Univ. of Texas, Austin). Talanta; 18: No. 4, 411-27(Apr 1971).**

Ruthenium(III) chloride and 3,4-diaminobenzoic acid, in aqueous solution at pH 4.0 to 4.5, react slowly at room temperature, but more rapidly when the mixture is heated, giving solutions that go through colour transitions from amber to purple-red; maximum absorbance of fully developed solutions occurs at 550 nm. The effects of heating temperature and time, pH, reagent concentration, and other variables were studied. The system conforms to Beer's law; optimum concentration range, for measurement in 10-mm cells, is about 0.5 to ppM of ruthenium. Interference from foreign ions, especially other platinum elements, is avoided by a distillation separation of ruthenium. The spectrophotometric mole-ratio and continuous-variation methods indicated the presence of complexes of 1:2 and 1:3 ruthenium-to-reagent stoichiometry. Elemental analysis of solid products isolated from solution confirmed the 1:2 reaction ratio. Several other o-diamines gave similar coloured solutions and reaction stoichiometry. (auth) (UK)

57326 SPECTROPHOTOMETRIC DETERMINATION OF CADMIUM IN NUCLEAR-GRADE ZIRCALOY-2 AFTER SELECTIVE EXTRACTION WITH A LIQUID ANION-EXCHANGER. **Ghersini, G.; Mariottini, S. (CISE, Milan). Talanta; 18: No. 4, 442-6 (Apr 1971).**

A method is presented for the spectrophotometric determination of cadmium in Zircaloy-2 at the tenths of ppM level. The method involves the extraction of Cd with tri-n-octylamine from 1M HCl, its separation from Fe(III) by scrubbing with tartaric acid, its recovery with 2M sulphuric acid, and the final development of the Cd-dithizonate colour. The method is simple and rapid, does not require any special instrumentation, and avoids the use of toxic reagents. Cadmium at the 0.3-ppM level was determined with standard deviation 0.054 ppM. (auth) (UK)

57327 INCREASING THE ACCURACY OF TANTALUM DETERMINATION IN ORE-DRESSING PRODUCTS BY A X-RAY-RADIOMETRIC METHOD BY MEANS OF A K-JUMP OF ABSORPTION. **Abdulin, S. F. (Krasnoyarsk Inst. of Nonferrous Metals, USSR). Zh. Anal. Khim.; 26: No. 9, 1825-8(Sep 1971). (In Russian).**

A method is suggested for eliminating the filler effect during analysis by means of a K-jump of absorption. The method was used in the x-ray-radiometric analysis of ore-dressing products for tantalum. (auth)

57328 CONDITIONS FOR THE LUMINESCENCE DETERMINATION OF URANIUM IN SILICON DIOXIDE OF HIGH PURITY. **Dobrolyubskaya, T. S. (Inst. of Geochemistry and Analytical Chemistry, Moscow). Zh. Anal. Khim.; 26: No. 9, 1835-6(Sep 1971). (In Russian).**

Optimum conditions for the luminescence determination of uranium as an impurity in silicon dioxide of special purity with a sensitivity of ~3×10^{-6}% were established. (auth)

57329 DETERMINATION OF THE OXYGEN CONTENT IN METALLIC RUTHENIUM. **Karlenko, G. S.; Burtsev, V. T.; Smirnov, Yu. A.; Polonskii-Bulaev, A. A. (Inst. of Metallurgy, Moscow). Zh. Anal. Khim.; 26: No. 9, 1843-5(Sep 1971). (In Russian).**

The content of oxygen in ruthenium was determined by the vacuum-fusion method by means of an auxiliary nickel–iron–carbon melt at a temperature of 1650°C and an extraction time of 7 min. The analysis was carried out with additives of tin at a dilution of 1:10. (auth)

57330 ELIMINATION OF THE EFFECT OF THE SAMPLE COMPOSITION ON THE LINE INTENSITY OF CERTAIN RARE METAL IMPURITIES. **Pometun, E. A.; Romaikina, E. P.; Korsun, V. I.; Gazieva, M. T.; Khaimova, Sh. M. (Tadzhik State Univ., Stalinabad, USSR). Zh. Anal. Khim.; 26: No. 9, 1706-9 (Sep 1971). (In Russian).**

The possibility of eliminating the effect of the composition of analyzed powders on the results of the spectrographic determination of niobium, tantalum, zirconium, and hafnium by treating the samples with H_2F_2 and chlorination in a chamber electrode is discussed. The possibility of chlorinating complex compounds of these metals that form in a H_2F_2 medium was proved by thermodynamic calculations taking as an example potassium fluoro- and oxyfluoroniobates. (auth)

57331 CONDITIONS FOR CERIUM SORPTION BY CHROMATOGRAPHIC PAPER MODIFIED WITH CARBOXYLIC ACIDS FOR ITS DETERMINATION BY THE PEROXIDE METHOD. **Ganopol'skii, V. I.; Krivonozhnikova, L. G.; Ermolenko, I. N. (Inst. of General and Inorganic Chemistry, Minsk). Zh. Anal. Khim.; 26: No. 9, 1757-63(Sep 1971). (In Russian).**

Conditions were studied for cerium sorption by chromatographic paper modified with citric acid. Sorption under static and dynamic conditions was examined. The best variant is cerium sorption by passing the solution through the paper sample at a rate of 2 ml/min. The optimum volume of the test solution is 100 ml. The concentration of the element in the solution is directly proportional to the amount of cerium sorbed by the paper, just as the cerium content in the sample is directly proportional to the intensity of the reflected radiation. The sensitivity is down to 10^{-8} mole of cerium or 1.7 μg of CeO_2. The mean square error of cerium determination in the range 0.3×10^{-7} to 1×10^{-7} mole is 5.4% relative. (auth)

57332 DETERMINATION OF EUROPIUM, TERBIUM, SAMARIUM, AND DYSPROSIUM IN OPTICAL FLUORITE. **Galkina, L. L.; Strel'tsova, S. A. (Central Asian Scientific-Research Inst. of Geology and Mineral Resources, Tashkent). Zh. Anal. Khim.; 26: No. 9, 1764-6(Sep 1971). (In Russian).**

A method was developed for isolating very small amounts of the rare earth elements from fluorite by extraction with butyric acid. Separate rare earths are then determined by spectrographic and fluorimetric methods. By means of the fluorimetric method it is possible to determine down to 5×10^{-7}% Eu_2O_3, 5×10^{-5}% Sm_2O_3, $n \times 10^{-6}$% Tb_4O_7, and $n \times 10^{-5}$% Dy_2O_3 in fluorite. (auth)

57333 REZARSON AS A REAGENT FOR THE SPECTROPHOTOMETRIC DETERMINATION OF NIOBIUM. **Lukin, A. M.; Kaslina, N. A.; Petrova, G. S. (All-Union Scientific Research Inst. of Chemical Reagents and Specially Pure Chemicals, Moscow). Zh. Anal. Khim.; 26: No. 9, 1782-5(Sep 1971). (In Russian).**

2,2′,4′-Trihydroxy-3-arsono-5-chloroazobenzene (rezarson) was studied as a reagent for the spectrophotometric determination of niobium. A 50% water–ethanol medium 1 N with respect to HCl is most suitable for determination of niobium. The stoichiometric ratio of the components is $[R]:[Nb] = 1:1$. The molar extinction coefficient of the reagent is 1.6×10^3, that of the complex is 1.94×10^4, the equilibrium constant is 6.5×10^5. A method was developed for determining niobium in ores. (auth)

57334 POLAROGRAPHIC DETERMINATION OF URANIUM IN MONAZITE SANDS. **Martres, R. W.; Burastero, J. J. (Centro de Investigaciones Tecnologicas, Pando, Uruguay). Analyst, 96: No. 1145, 579 83(Aug 1971).**

The extraction of uranium from monazite sands and its subsequent polarographic determination are described. The sample is decomposed by fusion with potassium hydrogen difluoride followed by fusion with potassium pyrosulphate. Uranium is extracted from nitric acid solution with tributyl phosphate in 2,2,4-trimethylpentane, with aluminum nitrate as a salting-out agent, and back-extracted from the organic phase with water. The final polarographic determination is carried out in 2 M acetic acid–2M ammonium acetate–0.1 M ascorbic acid solution as supporting electrolyte. Neither a maximum suppressor nor removal of oxygen is needed. The interference by lead and some factors influencing the extraction of uranium are studied. The results are reproducible and agree with those obtained by other, more laborious, techniques. The proposed procedure is suitable for the determination of uranium in monazites and monazite sand concentrates containing not less than 0.005% of uranium oxide, and is superior in speed, reliability, and convenience to other methods previously reported. (auth)

57335 INFLUENCE OF VARIOUS CARRIERS IN THE SPECTROGRAPHIC ANALYSIS OF OXIDES OF REFRACTORY METALS (TUNGSTEN AND ZIRCONIUM). **Pevtsov, G. A.; Raginskaya, L. K.; Manova, T. G.; Sotnikova, V. S. Tr. Vses. Nauch.-Issled. Inst. Khim. Reaktivov; No. 31, 150-7(1969). (In Russian).**

In an attempt to improve the sensitivity of the direct spectrographic determination of Cr, Co, Cu, Ni, V, Fe, and Mn in tungsten trioxide and zirconium dioxide, a study was made of the effects on the line intensities of additions of certain halides. The zirconium dioxide sample is mixed with AgCl and NaCl, and the spectrum is excited in a 12-A dc arc. The tungsten trioxide procedure is similar, but powdered carbon is added, and the carrier is KI–NaF (4:1). The sensitivity is 1 ppM for Cr, Co, Fe, Ni, or V, and 0.5 ppM for Cu or Mn. (Referativnyi Zh.)

57336 HIGHLY SENSITIVE METHODS FOR DETERMINING TRACES OF MOLYBDENUM AND OTHER ELEMENTS, BASED

ON AMPEROMETRY, COLORIMETRY, AND PHOTOMETRY. IV. KINETIC BIAMPEROMETRIC DETERMINATION OF NANOGRAM AMOUNTS OF MOLYBDENUM. Shafran, I. G.; Rozenblyum, V. P.; Shteinberg, G. A. Tr. Vses. Nauch.-Issled. Inst. Khim. Reaktivov; No. 31, 171-82(1969). (In Russian).

The method is based on the catalytic action of Mo on the oxidation of KI by H_2O_2. Vibrating Pt electrodes are placed in an amperometric cell containing the test sample to which H_2SO_4 and KI have been added. One minute after an addition of 0.0125M H_2O_2, the current–time curve is recorded for 5 to 7 min. The content of Mo is found from the slope of the resulting graph along with a calibration graph. The effects of a number of other elements were studied. The literature on the determination of traces of Mo, the forms in which Mo may be present in solution, and kinetic amperometric and biamperometric methods of analysis is reviewed. (87 references.) (TSS)

57337 FUNDAMENTAL STUDY ON THE COLLECTION OF URANIUM IN SEAWATER. Ogata, Noboru (Japan Monopoly Corp., Tokyo). Nippon Kaisui Gakkaishi; 24: No. 5, 197-212 (Feb 1971). (In Japanese).

Through the course of a fundamental study on the collection of uranium in seawater, an extensive improvement was made in the separating and determining methods of uranium. Various studies were made on the collecting methods of uranium in seawater, the adsorption method with titanic acid being the most effective. Chemical species of uranium in seawater were researched by the stability constants of such components as Na^+, K^+, Ca^{2+}, Mg^{2+}, Cl^-, SO_4^{2-}, F^-, PO_3^{3-}, HPO_3^{2-}, CO_3^{2-}, OH^-, and UO_2^{2+}. As consequence, most of the dissolved uranium species were found to be $UO_2(CO_3)_3^{4-}$. The adsorption mechanism of uranyl carbonate complex ion on titanic acid was presumed an anion exchange reaction. The adsorption of uranium was governed by the kind of titanic acid, the temperature of seawater, the contacted volume of seawater, and the concentration of uranium in seawater. (auth) (Japan)

57338 DETERMINATION OF CERIUM IN REFRACTORY ALLOYS WITH USE OF CHROMATOGRAPHIC SEPARATION. Fokina, L. S.; Fedorova, N. D.; Kurbatova, V. I.; Nikulina, I. N.; Zhilkina, S. P. Tr. Vses. Nauch.-Issled. Inst. Stand. Obraztsov Spektr. Etalonov; 5: 118-22(1969). (In Russian).

The method is based on removal of Ti, Fe, Cu, and (in part) Zr from a HCl solution of the sample by ion exchange, followed by concentration and separation of Ce from Ni, Al and Mn by ion exchange in HNO_3–acetic acid medium. The Ce is determined photometrically. A detailed procedure is given. (TSS)

57339 USE OF ION-EXCHANGE CHROMATOGRAPHY IN DETERMINATION OF VANADIUM IN FERROVANADIUM AND IRON ORE. Studenskaya, L. S.; Stepin, V. V.; Vorozhbitskaya, K. F. Tr. Vses. Nauch.-Issled. Inst. Stand. Obraztsov Spektr. Etalonov; 5: 83-91(1969). (In Russian).

Aqueous solutions of ferrovanadium or iron ore samples are prepared and the acidity adjusted. The solution is passed through a column of cationite KU-2, previously washed with 0.5N H_2SO_4 containing 1% H_2O_2. This acid solution is used for washing the column to remove all of the V. Fe, Al, and Mn remain on the column. The washings are evaporated then titrated with an Fe(II) salt solution with a potentiometric indication of the end-point. The method has also been used for the analysis of titanomagnetite. (TSS)

57340 SPECTROPHOTOMETRIC DETERMINATION OF TRACES OF SILICON AS MOLYBDENUM BLUE IN URANIUM DIOXIDE. Rajkovic, D. (Inst. for Tech. of Nuclear Raw Materials, Belgrade). Z. Anal. Chem.; 255: No. 3, 190-4(1971).

A procedure for the determination of small amounts of silicon in uranium dioxide is described. Silicon is determined directly in the sample solution by means of the molybdenum blue method with 1-amino-2-naphthol-4-sulfonic acid as a reducing agent. Contents down to 5 ppM can be determined with an error not exceeding ±5%. (auth)

57341 SUCCESSIVE DETERMINATION OF URANIUM AND THORIUM IN OXIDES OF THE RARE EARTH ELEMENTS. Rusakova, V. P.; Solonovich, V. F.; Kalmykova, I. S. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 153-4(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 153-4(Jan-Feb 1971).

The joint extraction of microgram quantities of uranium and thorium with the aid of TBP was studied for analytical applications. An extraction method was proposed for the successive separation of uranium, thorium, and rare earth elements. Successive photometric determination of uranium and thorium in amounts of 0.01 to 0.001% in oxides of the rare earth elements is proposed. (auth)

57342 PHOTOMETRIC METHOD FOR THE DETERMINATION OF ULTRAMICROQUANTITIES OF THORIUM IN ROCKS. Gumbar, K. K.; Bozhichko, M. A. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 155-7(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 155-7(Jan-Feb 1971).

A photometric method was developed for the determination of ultramicroquantities of thorium in rocks of various compositions. The conditions of chromatographic separation of thorium from the rare earth elements, U, Zr, Sc, and other elements on the anion exchange resin Dowex 1X10 in nitric acid medium were investigated. (auth)

57343 POSSIBILITIES OF SPECTROPHOTOMETRIC DETERMINATION OF URANIUM IN WASHING, PROCESSING, AND WASTE WATERS FROM NUCLEAR POWER PLANTS. Parimucha, F.; Rostek, J. (Atomova Elektraren, Jaslovske Bohunice, Czech). Radioisotopy; 11: No. 5, 865-72(1970). (In Czech).

Spectrophotometric uranium determination in washing, processing, and waste waters by means of Chromazurol S in the presence of gelatin as detergent is described. Uranium is determined at $\lambda = 590$ nm and pH = 3.0 ± 0.1. The determination sensitivity is reduced in comparison with other methods but by concentration of uranium on the annex Amberlite 402 in the SO_4^{2-} cycle, the decreased sensitivity is compensated. (auth)

57344 (CEA-R-4218) TECHNIQUES OF CONTINUOUS MEASUREMENT OF RADIOACTIVE FISSION GASES EVOLVED IN FUEL ELEMENTS. Chenebault, Pierre; Hairion, Jean-Pierre; Kurka, Gerard (Commissariat a l'Energie Atomique, Grenoble (France). Centre d'Etudes Nucleaires). Jul 1971. 17p. (In French). Dep. NTIS (U. S. Sales Only).

The sampling circuits installed at the CEN–Grenoble allow radioactive rare gases, with half-lives greater than or equal to three minutes, released from nuclear fuel elements, to be analyzed. The separation of xenon from krypton by gas chromatography led to an enhancement in the quality of the gamma spectra obtained using Li-doped Ge detectors. (France)

57345 (CONF-711002–, pp 293-306) ASSAY OF SAMPLES FOR NUCLEAR MEASUREMENTS BY COUNTING AND CHEMICAL ANALYSIS. Lauer, K. F. (European Atomic Energy Community, Geel (Belgium). Central Nuclear Measurements Bureau). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

The nondestructive and destructive methods of analysis used in the fabrication of targets to be used for quantitative cross-section measurements are described. The experience and problems at the Central Bureau for Nuclear Measurement with isotopes of the actinide elements and rare earth samples are reviewed. (D.H.M.)

57346 (IFA-FR-82) DETERMINATION OF THE CONCENTRATION OF ^{59}Fe IN THE COOLANT WATER OF VVR-S REACTOR. Ionescu, E.; Ionescu, G.; Alexan, Z. (Institutul de Fizica Atomica, Bucharest (Romania)). 1971. 11p. Dep. NTIS (U. S. Sales Only).

The concentration of ^{59}Fe in the coolant water of a VVR-S type reactor can be determined by two methods: scintillation gamma spectrometry and polarography. To separate the energy lines of ^{60}Co and ^{59}Fe in the coolant water samples from the primary circuit, which have very close concentrations, the activities were measured two times; at the first determination the sum concentration corresponding to ^{60}Co and ^{59}Fe was measured and after a time interval sufficiently long to allow the disintegration of ^{59}Fe, the activity corresponding to ^{60}Co only was determined. Subtracting the values of ^{60}Co activities corrected for time, values for the ^{59}Fe activities and concentrations were obtained. The results obtained by scintillation spectrometry are highly consistent with those determined by the polarographical method. (auth)

57347 (RT/PROT-(71)9) RADIOTOXICOLOGICAL ANALYSES USED AT CNEN. Testa, C.; Masi, G.; Bazzarri, S.; Marchionni, V.; Santori, G. (Comitato Nazionale per l'Energia Nucleare, Rome (Italy)). 14 Apr 1971. 110p. (In Italian). Dep. NTIS (U. S. Sales Only).

Methods of radiotoxicological analyses in use at CNEN are described. A short introduction reports the sampling of biological samples, the sampling intervals, and the reference levels. The different techniques for the determination of α, β, and γ emitters in biological samples are then described, i.e., the determination of ^{210}Po, ^{226}Ra, natural thorium, natural uranium, enriched uranium, plutonium, gross alpha activity, tritium, ^{90}Sr, gross beta activity, gamma emitters, and of creatinine in urine; the analyses of α, β, and γ emitters in nose blow and feces samples are finally reported. Some schedules are presented for the registration of the values obtained. (auth)

57348 (TID-25777) 1971 RESULTS FOR THE INTERCOMPARISON OF ANALYTICAL METHODS FOR ^{137}Cs AND ^{134}Cs USED AT SCRIPPS WITH METHODS USED AT 56 OTHER INSTITUTIONS. Hodge, V. F.; Folsom, T. R.; Hansen, N. (Scripps Institution of Oceanography, La Jolla, Calif.). 16 Mar 1971. Contract AT(04-3)-34. 9p. Dep. NTIS.

The method used at Scripps for determining the ^{137}Cs and ^{134}Cs in seawater is described. The cesium was precipitated by ammonium 12-molybdophosphate (AMP) and dried for γ counting; the supernatants were then scavenged with ferric hydroxide, precipitated a second time by AMP, and dried for γ counting. All AMP and ferric hydroxide precipitates were counted above a 5′ × 4′ sodium iodide scintillator crystal, using a conventional 200-channel analyzer. Since the samples were mixtures of ^{137}Cs and ^{134}Cs, the 0.605-MeV peak of ^{134}Cs partially overlapped the FWHM area of ^{137}Cs. Therefore, the first AMP precipitates were counted again with a two-dimensional sodium iodide spectrometer. The results obtained showed good agreement with those from Battelle Northwest Laboratory. (D.H.M.)

57349 MICROANALYTICAL DETERMINATION OF CARBON AND HYDROGEN, ^{14}C, TRITIUM AND DEUTERIUM IN A STREAM OF NITROGEN. Frohofer, H. (Univ., Zurich). Z. Anal. Chem.; 253: No. 2, 97-102(1971). (In German).

A microanalytical method for the determination of carbon and hydrogen is described. The procedure involves the combustion of the organic substance in a stream of nitrogen and the oxidation of the decomposition products with oxygen. Halogens and sulphur are absorbed by the combustion catalyst (according to Körbl), whereas nitrogen oxides are reduced on a copper surface. The combustion products, CO_2 and H_2O, are determined gravimetrically; in the case of radioactive samples they are appropriately absorbed and counted in a liquid scintillation counter. Strongly quenching singly and doubly labeled samples, which cannot be accurately counted even by modification of the counting device, give equally high radioactive yields (75% for ^{14}C, 30% for ^{3}H), since counting is not influenced by other gaseous impurities. Deuterium is quantitatively determined by measuring the intensity of the OD-signal at 2500 cm^{-1} with an infrared spectrometer. (auth)

57350 ANALYSIS OF RADIOPHARMACEUTICALS. Jaffee, Max; Ford, Leonard (Food and Drug Administration, Washington, D. C.). J. Ass. Offic. Anal. Chem.; 54: No. 4, 879-83(Jul 1971).

Some of the activities of chemists engaged in evaluating and selecting analytical methodology for examination of radiopharmaceuticals and the criteria for assessment of their quality are described. Significant problems, as they relate to a regulatory analysis program, and tentative solutions to these problems are discussed. Conclusions and recommendations, based on the results of analysis of selected radiopharmaceutical preparations of commercial origin, are given. (auth)

57351 EVALUATION OF ION-EXCHANGE SURVEILLANCE SAMPLER FOR ANALYZING RADIOACTIVE LIQUID EFFLUENTS. Krieger, H. L.; Frishkorn, G. W. (Bureau of Radiological Health, Cincinnati). Health Phys.; 21: No. 4, 591-5(Oct 1971).

Data are presented for ^{58}Co, ^{60}Co, ^{89}Sr, ^{90}Sr, ^{131}I, ^{134}Cs, ^{137}Cs, and ^{140}Ba$-^{140}$La at 10^{-1} pCi/levels in reactor effluent water at the point of release. Analysis of these nuclides in environmental media provides needed information with respect to their critical pathways and the calculation of radiation exposure to the population. The low levels of radionuclides in aqueous media can be determined by processing large sample volumes through a multisection column of cation- and anion-exchange resins. The column concentrates these radionuclides from 200 l of water having as much as 250 ppM hardness, or from larger volumes of softer water. The column dimensions were designed on the basis of tracer studies with ^{137}Cs, ^{85}Sr, ^{60}Co, and ^{131}I to assure almost complete retention of these nuclides in the uppermost section of the cation- or anion-exchange resins. The nuclides that emit γ rays are identified by spectrometer, and all radionuclides are determined radiochemically after eluting them from the sections with 6 N HCl. (auth)

57352 NEW METHOD FOR THE SEPARATION OF MULTICURIE QUANTITIES OF ^{90}Y FROM ^{90}Sr. Kanapilly, G. M.; Newton, G. J. (Lovelace Foundation for Medical Education and Research, Albuquerque, N. Mex.). Contract AT(29-2)-1013. Int. J. Appl. Radiat. Isotop.; 22: No. 9, 567-75(Sep 1971).

A simple, economical method for the separation of ^{90}Y from ^{90}Sr$-^{90}$Y was developed. The technique consisted of forming colloidal yttrium hydrogen phosphate under precisely controlled conditions and separating the ^{90}Y from ^{90}Sr by filtration. This method was used to prepare several multicurie samples of ^{90}Y with specific activities of 5×10^4 Ci/g. Recoveries of ^{90}Y at nearly 100% with ^{90}Sr contamination of less than 1×10^{-6}% of that of ^{90}Y were routinely achieved. The basic technique with appropriate changes was adapted for the rapid assaying of ^{90}Sr contamination in the ^{90}Y sample and for the preparation of ^{140}La from ^{140}La$-^{140}$Ba. (auth)

57353 PRACTICAL METHOD FOR RESOLUTION OF TWO β-EMITTING RADIONUCLIDES BY LIQUID SCINTILLATION COUNTING. Snipes, M. B.; Lengemann, F. W. (Cornell Univ., Ithaca, N. Y.). Contract AT(30-1)-4039. Int. J. Appl. Radiat. Isotop.; No. 9, 513-20(Sep 1971).

A practical method for resolution of mixtures of two β-emitting radionuclides is described utilizing liquid scintillation counting procedures that combine simplicity of quench correction with the reliability of the discriminator ratio method of double-label counting. A channel is set for each radionuclide, allowing 10% overlap of the lower energy member into the channel set for the higher energy member, and quench correction standards and experimental samples are counted with and without an external standard. Simultaneous equation solutions are used, which make optimal use of channels ratio data available by direct print-out. If R_A and R_B equal net cpm in channels A and B, R_a and R_b equal net cpm for radionuclides a and b, and F_a^{-1} and F_b equal the channels ratio A/B for radionuclides a and b, then $R_a = (F_b R_B - R_A)/(F_a F_b - 1)$ and $R_b = (F_a R_A - R_B)/(F_a F_b - 1)$. Values for F and counting efficiency (to convert cpm to dpm), as functions of the channels ratio A/B for the external standard, may be graphically derived from the quench correction graph made using counting data for the appropriate quench correction standards. Absence of restrictions and ease of adaptation make the method applicable to any pair of β-emitting radionuclides sufficiently different in energy to be accurately resolved; this can be determined from a plot of percent error in resolution of each radionuclide as a function of the ratio of the amounts of each member present in the mixture. (auth)

57354 DETERMINING THE CONTENT OF CHEMICAL ELEMENTS OR ISOTOPES THEREOF IN A SPECIMEN BY UTILIZING THE EFFECT OF RECOILLESS RESONANCE ABSORPTION OR SCATTERING OF GAMMA RAYS. Dolenko, Anatoly Vasilievich; Egiazarov, Boris Grigorievich; Isakov, Lev Mikhailovish; (and others). U. S. Patent 3,597,615. 3 Aug 1971. Filed 28 Feb 1967.

An arrangement and process for determining the content of chemical elements, isotopes, or compounds in a specimen are presented. Measurements are made during irradiation of the specimen with gamma rays of a quantity that is proportional to the content of the element, isotope, or compound in the specimen. (auth)

57355 METHODS OF DETERMINATION OF ^{137}Cs IN OBJECTS OF THE EXTERNAL ENVIRONMENT. Shvydko, N. S.; Popov, D. K.; Borichev, A. A.; Mikhailova, O. A. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 97-102(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 102-7(Jan-Feb 1971).

A survey of the methods of determination of ^{137}Cs in objects of the external environment is cited. A method is suggested for the determination of ^{137}Cs, providing for a combination of potassium-cobalt ferrocyanide concentration of the cesium with γ spectrometry or a measurement of the β activity of the adsorbent. (auth)

57356 DETERMINATION OF COBALT IN NICKEL PREPARATIONS BY A RADIOCHEMICAL METHOD. Shamaev, V. I.; Garbauskas, G. K.; Martynov, A. M. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 88-91(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 94-7(Jan-Feb 1971).

The possibility of direct determination of Co in nickel preparations with a substoichiometric amount of 1-nitroso-2-naphthol by the method of radiometric correction was studied. The possibility of determining Co in the presence of a large (up to 100-fold) excess of Ni with preliminary isolation of Co by the nitrite method, followed by determination with a substoichiometric amount of 1-nitroso-2-naphthol, was studied. A simple, rapid, and sufficiently accurate radiometric method was developed for the determination of Co in Ni with the aid of a calibration curve. (auth)

57357 STUDY OF THE BEHAVIOR OF VARIOUS VALENCE FORMS OF PLUTONIUM IN THE ACID–TBP SYSTEM BY THE METHOD OF THIN-LAYER CHROMATOGRAPHY ON SILICA GEL. **Volynets, M. P.; Milyukova, M. S. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 67-72(Jan-Feb 1971).**

Translated from Radiokhimiya; 13: No. 1, 72-8(Jan-Feb 1971).

The distribution of different valence forms of plutonium in systems of acid–TBP was studied by the method of thin-layer chromatography on silica gel. It was established that Pu(IV) and Pu(VI) are quantitatively concentrated at the line of the solvent front when they are sorbed for 3 to 5 N HNO_3. A quantitative separation of Pu(IV) and Pu(VI) from Pu(III) is possible in the system 3N HNO_3–23% solution of TBP in synthine. The method of thin-layer chromatography permits an easy and comparatively rapid detection of the disproportionation of tetravalent plutonium in nitric acid and perchloric acid solutions. In the case of a single chromatography on a layer of silica gel impregnated with 3N HNO_3 (on one part of the plate), as well as 1N $HClO_4$ (on the adjoining section), using a 23% solution of TBP in synthine as the mobile solvent, plutonium can be quantitatively separated from U, Zr, Ni, Pb, Cu, Cr, and Fe, and the rare earth elements, and it can be determined radiometrically in the zone on the plate with an accuracy of ±10 to 15%. The time of analysis was 60 to 90 min. The volume of the solution to be analyzed was 0.03 ml. (auth)

57358 PREPARATION OF GAS SAMPLES FROM CARBONATES AND THEIR SOLUTIONS FOR THE MEASUREMENTS OF THE ACTIVITY OF ^{14}C. **Zhukovskaya, L. P.; Karavaev, F. M.; Sokolova, I. A. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 165-6(Jan-Feb 1971).**

Translated from Radiokhimiya; 13: No. 1, 163-4(Jan-Feb 1971).

The ^{14}C in the salt sample or solution is completely converted to CO_2, which is introduced, in exactly known amounts, to proportional counters. The error in measurement using this method is 1.5 to 2%. (M.C.G.)

57359 ANALYSIS OF CONTAMINATIONS IN BIOLOGICAL SAMPLES BY HEAVY ION SCATTERING. **Seaman, G. G.; West, J. K. (Kansas State Univ., Manhattan). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 87-90(Feb 1971).**

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

In the elastic scattering of a moving ion by a stationary target nucleus, the maximum scattering angle in the laboratory reference frame is equal to, or less than, 90° if the mass of the scattering nucleus is equal to, or less than, that of the incident ion. Thus, beams of oxygen ions incident upon a biological sample composed of only carbon, hydrogen, and oxygen will not scatter into a detector placed at an angle greater than 90°. Any element heavier than oxygen scatters incident oxygen ions into such a detector. This particular choice of incident ion and detector position discriminates against the bulk of the material in a biological sample and allows detection of only the minor constituents. Accelerated beams of 20- to 30-MeV oxygen ions from the Kansas State University tandem Van de Graaff accelerator were used in this technique. Initial studies have centered upon determining the contaminations that are present in flour. Thick targets are used, so that the beam is stopped entirely within the sample. The spectrum consists of a continuous distribution of energies up to a maximum energy, corresponding to ions scattering from the surface of the sample. This maximum energy determines the mass of the contaminant nuclei, while the number of scattered particles is proportional to the quantity of contaminant nuclei. (auth)

57360 DETERMINATION OF TRACE ELEMENTS IN SAMPLES BY NUCLEAR SCATTERING AND REACTION TECHNIQUES. **Jolly, R. K.; Gruhn, C. R.; Maggiore, C. (Michigan State Univ., East Lansing). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 91-5(Feb 1971).**

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The feasibility of using low-energy (15- to 25-MeV) α-particle scattering for detecting traces of heavy elements in a bulk of light elements, as, for example, in biological and environmental matter, is explored. These measurements can provide information on all the elements in the same simultaneously. Heavy elements require good energy resolution (~10 keV) for definite identification while light elements can be identified even with very poor energy resolution ($\geq$100 keV). Results of some measurements on a fish sample are presented. Similarly, sub-Coulomb (p, α) reactions are explored for measuring traces of very light elements in a bulk of heavy elements. Suitable choice of bombarding energy almost completely suppresses the contribution from the heavy element. Results of a measurement in a very pure Zr sample are presented. (auth)

57361 LIQUID SCINTILLATION COUNTING OF ^{45}Ca IN SOFT TISSUES. **Patrick, G.; Stirling, C. (Medical Research Council, Harwell, Eng.). Int. J. Appl. Radiat. Isotop.; 22: No. 10, 627-9(Oct 1971).**

A method was developed for counting ^{45}Ca in soft tissue, such as rat small intestine, at high efficiency with short preparation time. The calcium was present as a calcium oxalate precipitate. By carrying out the whole process of sample preparation of the oxalate in the counting vial the main difficulties associated with counting the soluble calcium salts were overcome. The counting efficiency was 87% with 5 mg calcium. The amount of calcium precipitated in the vial affected the counting efficiency and reproducibility very little up to 60 mg Ca but above this the efficiency was markedly reduced. For most purposes envisaged it was shown that no quench correction was required. (UK)

57362 UNFOLDING OF EXPERIMENTAL ALPHA-PARTICLE SPECTRA FOR DETERMINATION OF THE SPECIFIC ACTIVITY OF ALPHA-EMITTING NUCLIDES IN BIOASSAYS IN THE MILLIGRAM RANGE. **May, H. P. (Gesellschaft fuer Strahlenforschung mbH, Frankfurt am Main). pp 665-85 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).**

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The decay energy and the specific activity must be known in order to estimate the absorbed energy. In the case of alpha-particle-emitting nuclides both can be simultaneously determined for bioassays in the milligram range by alpha-particle spectrometry. A mathematical evaluation method for determination of the specific activity, based on the approximate unfolding of alpha-particle spectra detected by a plane parallel, gridded ionization chamber and stored by a multichannel pulse-height analyzer is outlined. The radionuclides used were ^{241}Am and ^{232}Th with its decay products. (auth)

57363 COUNTING TRITIATED WATER. **Francois, B.; Limandas, M. (Hopital de l'Antiquaille, Lyon). Int. J. Appl. Radiat. Isotop.; 22: No. 10, 632-3(Oct 1971).**

A comparative assay was made of five commonly used scintillating media for counting tritiated water in aqueous solutions; Bray solution, toluene–triton, Ne 240^R and Ne 250^R (Nuclear Enterprises, Ltd.) and Instagel^R (Packard Instrument Company, Inc.). Results obtained using three different figures of merit are tabulated. It was concluded that for medical use 10 ml Instagel plus 4 ml aqueous sample is a combination to be strongly recommended on the basis of efficiency, volume of aqueous sample incorporated, and saving of scintillating solution. (UK)

57364 ^{14}C IN ATMOSPHERE AND BIOSPHERE. **Chudy, M.; Povinec, P.; Seliga, M.; Saro, S. (Katedra Jadrovej Fyziky Prirodovedeckej Fakulty UK, Bratislava). Radioisotopy; 11: No. 5, 935-51(1970). (In Czech).**

The determination of ^{14}C in atmospheric carbon dioxide and biological samples is described. The activity of the samples is measured using a gas-filled proportional counter. The working characteristics of the counter and possibilities of its use in low ^{14}C activity measurements were studied. The influence of conditions during measurement on results is discussed and some corrections are presented. The results of measurements of relative ^{14}C excess in atmosphere and biosphere over the natural levels are presented. (auth)

57365 ^{226}Ra ACTIVITY DETERMINATION IN NON-EQUILIBRIUM STATE BY SCINTILLATION GAMMA SPECTROMETRY. **Lenger, V.; Thomas, J. (Ustav Hygieny Zareni, Prague). Radioisotopy; 11: No. 5, 797-811(1970). (In Czech).**

A gamma spectrometric method of activity determination in nonequilibrium state was elaborated, based on the utilization of the time course of ^{214}Pb and ^{214}Bi activities during return to equilibrium in a hermetically sealed ^{226}Ra reference source. The principle of the method can be generalized to the complete analysis of the Ra, ^{214}Pb, and ^{214}Bi mixture in an arbitrary grade of equilibrium. (auth)

57366 DOSIMETRIC CHECKING OF ^{90}Sr IN THE BIOLOGICAL CHAIN. **Benes, J.; Tomasek, M. (Radiologicka Dozimetrie UJV CSAV, Prague). Radioisotopy; 11: No. 5, 823-34(1970). (In Czech).**

A procedure for isolation of radiostrontium from natural samples based on the precipitation of insoluble sulfates and chromates from EDTA medium is proposed. This procedure is suitable for dosimetric determination of ^{90}Sr in chemically complex systems. (auth)

57367 SEPARATION OF RADIOIODIDE FROM SIMULATED BIOLOGICAL SAMPLES BY ISOTOPIC EXCHANGE IN A HET-

XUM

EROGENEOUS SYSTEM. Stollarova, N.; Zaduban, M. (Prirodovedecka Fakulta UPJS, Kosice, Czech.). Radioisotopy; 11: No. 5, 851-64(1970). (In Czech).

Possibilities of the determination of radioiodide by isotopic exchange in a medium of inorganic ions, amino acids, proteins, and in animal organs are described. The possibility of application of isotopic exchange to the measurement of radioiodide from aqueous solutions using liquid scintillators based on toluene was also investigated. (auth)

Activation Procedures

57368 (AED-C-14-5) BIBLIOGRAPHIES IN NUCLEAR SCIENCE AND TECHNOLOGY. Section 14: Activation Analysis. Bock-Werthmann, W.; Niebuhr, H.; Sansoni, B. (Zentralstelle fuer Atomkernenergie-Dokumentation, Frankfurt am Main (West Germany)). May 1971. 276p. (In English and German). Dep. NTIS (U. S. Sales Only).

57369 (RFT-Trans-83) RAPID DETERMINATION OF BORON IN GLASS BY PROMPT γ-RAY MEASUREMENT. Kusaka, Y.; Tsuji, H.; Egawa, M. Translated for Dow Chemical Co., Rocky Flats Div., from Nippon Kagaku Zasshi; 88: No. 9, 1006-8(1967). 8p. Dep. NTIS.

Nondestructive determination of boron in glass samples by using an americium–beryllium neutron source (300 mCi) and by measuring the 0.478-MeV prompt γ ray produced in the $^{10}B(n,\alpha)^{7}Li$ reaction is described. An appropriate arrangement of the neutron source, a paraffin block as a neutron moderator, a lead block as a radiation shield, a lithium fluoride plate as a neutron shield, a sample container, and a prompt γ detector are proposed. The detector was a NaI scintillator (1.5″ × 1″) connected to a 400 channel pulse height analyzer. This method is applicable for the glass with relatively low boron content (0.5 to 6.0% as B_2O_3). The analytical error was 2 to 4%, and it takes only 15 min for one run. (auth)

57370 RADIOACTIVATION DETERMINATION OF Se, Te, AND Au IN NATURAL WATERS. Abdullaev, A. A.; Sharipov, E. B.; Khudaibergenov, U.; Khasanov, A. S. (Inst. of Nuclear Physics, Tashkent). Izv. Akad. Nauk Uzb. SSR, Ser. Fiz.-Mat. Nauk; No. 2, 71-2(1971). (In Russian).

A radioactivation method was developed for simultaneously determining Se, Te, and Au in waters. The dried residues are irradiated, and combined with milligram quantities of inactive Se, Te, and Au as carriers. The subsequent extraction procedure is given in detail. Assay for the desired elements is made on a γ spectrometer using a NaI(Te) crystal. The sensitivity of the method is claimed to be 10^{-10} g/ml of Se or Au, and 10^{-9} g/ml of Te for an 8- to 10-hour exposure in the reactor. (K.S.W.).

57371 DETERMINATION OF TANTALUM IN SPHERE BY ACTIVATION ANALYSIS. Babaev, A.; Khaidarov, A.; Akramov, M. B.; Dusmatov, V. D. (Physical-Technical Inst., Dushanbe, USSR). Dokl. Akad. Nauk Tadzh. SSR; 14: No. 6, 22-5(1971). (In Russian).

In the search for an economical analytical method for Ta in sphene, samples of the latter were subjected to a neutron flux density of 1.8×10^{13} n/cm^2·sec for 5 hr and then "cooled" for 15 days to permit short-lived radioisotopes to decay. A γ spectrometer was used to obtain the gamma spectra of the standard and an unknown sample. The photopeak of ^{182}Ta (0.068 MeV), together with its half-life (111 days), leave little room for interference from the other naturally occurring components of sphene. (K.S.W.).

57372 EMISSION-SPECTRAL AND RADIOACTIVATION ANALYSIS OF YTTRIUM OXIDE WITH PRELIMINARY CONCENTRATION OF RARE EARTH IMPURITIES BY EXTRACTION CHROMATOGRAPHY. Zemskova, M. G.; Lebedev, N. A.; Melamed, Sh. G.; (and others). Nauch. Tr., Gos. Nauch.-Issled. Proekt. Inst. Redkometal. Prom.; 22: 116-20(1968). (In Russian).

A method of chemico-spectral analysis was developed for yttrium in a mixture of rare earths from lanthanum to holmium which surpasses the method of direct spectral analysis in sensitivity by a factor of 50 to 100. The preliminary concentration of rare earth impurities was accomplished in a column of silica gel that had been treated with a solution of dimethyldichlorosilane in CCl_4 and then impregnated with bis-(2-ethylhexyl) orthophosphate. It is proposed that yttrium forms a salt with the latter in the upper portion of the column. The rare earths were eluted with HCl and were coprecipitated with spectrally pure yttrium oxide if it was desired to complete the analysis with the aid of a spectrograph. An alternate procedure involves irradiation of the sample with thermal neutrons at a flux of 10^{13} n/cm^2 · sec for 20 min. This chromatographic-activation analytical method for Y in a rare earth mixture is more sensitive than the chemico-spectral method by one to three orders of magnitude. (K.S.W.)

57373 COMPARISON OF PAINTS BY NEUTRON ACTIVATION ANALYSIS. II. COLORED PAINTS. Snow, K. B.; Washington, W. D. (Internal Revenue Service, Washington, D. C.). J. Ass. Offic. Anal. Chem.; 54: No. 4, 917-19(Jul 1971). (CONF-701055-1).

From Meeting of the association of official analytical chemists; Washington, D. C. (12 Oct 1970).

A study of colored paints was made to determine to what extent individual paint samples can be characterized by neutron activation analysis. Approximately 300 samples of red, white, blue, and green paints from the major manufacturers in the United States were examined. Paints of the same color produced by different manufacturers could be distinguished by this technique. Batch-to-batch variations between paints from the same manufacturer were observed, and it was found that in a small number of cases no differences were detected. (auth)

57374 USE OF NEUTRON ACTIVATION ANALYSIS FOR THE CHARACTERIZATION OF PAPER. Brunelle, R. L.; Washington, W. D.; Hoffman, C. M.; Pro, M. J. (Internal Revenue Service, Washington, D. C.). J. Ass. Offic. Anal. Chem.; 54: No. 4, 920-4(Jul 1971). (CONF-701055-2).

From Meeting of the association of official analytical chemists; Washington, D. C. (12 Oct 1970).

A controlled study was carried out on 600 samples of various types of white and colored paper obtained from 10 different paper manufacturers with known production histories and dates. Neutron activation analysis was employed to measure the characterizing trace elemental compositions. Results indicated that (1) the papers examined were uniform with respect to their trace elemental compositions, (2) papers produced by different manufacturers are readily distinguishable qualitatively and/or quantitatively, (3) different batches of paper produced by the same manufacturer are generally qualitatively similar if produced within a short span of time (however, these specimens can be distinguished by quantitative analysis of the trace elements), and (4) different batches of paper produced by the same manufacturer at least 1 year apart are readily distinguishable qualitatively and/or quantitatively. (auth)

57375 DETERMINATION OF TRACE ELEMENTS IN SOILS AND CLAY MINERALS BY RESONANCE NEUTRON ACTIVATION ANALYSIS. Murrmann, R. P.; Winters, R. W.; Martin, T. G. (Army Natick Labs., Mass.). Soil Sci. Soc. Amer., Proc.; 35: No. 4, 647-52(Jul-Aug 1971).

Bentonites 23 and 25, Umiat bentonite, Koalinite 7, Halloysite 29, Illite 35, and Fairbanks, Barrow, and Suffield silts were irradiated with resonance neutrons by exposure of cadmium-shielded samples in a reactor for 40 hours in order to identify the elements having long half-life nuclides which could be quantitatively determined using nondestructive neutron activation analysis. By examination of the gamma spectra obtained using a high resolution Ge(Li) detector, it was possible to identify Fe, Ti, Zn, Ni, Co, Cr, Sr, Ba, Cs, La, Eu, Tb, Hf, Ta, Th, and U in most of the samples. Although quantitative results were obtained only for Fe, Ti, Zn, Ni, Co, and Cr, this method appears suitable for nondestructive quantitative analysis for all the elements identified. (auth)

57376 USE OF FAST 14-MeV NEUTRONS FOR DETERMINATION OF OXYGEN IN PURE MATERIALS. Andreev, A. V.; Pronman, I. M. Nauch. Tr., Gos. Nauch.-Issled. Proekt. Inst. Redkometal. Prom.; 22: 46-51(1968). (In Russian).

A method is described for determining oxygen in Ti, Nb, Mo, Sb, and GaAs based upon the fast neutron reaction $^{16}O(n,p)^{16}N$. The beta-emitting ^{16}N with a half-life of 7.4 sec decays with γ at 6.13 and 7.11 MeV. A gamma spectrometer was used to measure the activity of the sample, comparing the results with the activity of a standard with a known oxygen content. Standards were prepared from Plexiglas $(C_5H_8O_2)_n$, quartz (SiO_2), and marble ($CaCO_3$). The method is applicable to the majority of materials not containing significant amounts of B or F. (K.S.W.)

57377 EFFECT OF SLOWING-DOWN NEUTRONS IN THE SAMPLE ON THE RESULTS OF ACTIVATION ANALYSIS. Lisovskii, I. P.; Smakhtin, L. A.; Stariznyi, E. S. (Physical-Chemical Inst., Moscow). Zh. Anal. Khim.; 26: No. 8, 1658-9(Aug 1971). (In Russian).

The effect of increasing the flux of thermal neutrons within the mass of the irradiated sample should be taken into account during the activation determination of impurities in hydrogen-containing materials. (auth)

57378 NEUTRON ACTIVATION ANALYSIS OF TIN IN BIOLOGICAL SAMPLES BY A RAPID EXTRACTION SEPARATION OF ^{123m}Sn. Byrne, A. R. (Jozef Stefan Nuclear Inst., Ljubljana, Yugoslavia). Radiochem. Radioanal. Lett.; 7: No. 5-6, 287-93 (10 Sep 1971).

A method was developed for determination of tin in biological materials down to 0.1 ppM by a simple and rapid radiochemical procedure for ^{123m}Sn ($T = 40$ min), based on the extraction of tin iodide into toluene. (auth)

57379 IMPURITIES IN ANALYTICAL AND SUPRAPURE REAGENTS APPLICATION OF ACTIVATION ANALYSIS FOR THE DETERMINATION OF Cl, As, Cu, Mn, Na IN MINERAL ACIDS, AMMONIA, AND HYDROGEN PEROXIDE. Kosta, L.; Ravnik, V. (Univ., Ljubljana, Yugoslavia). Radiochem. Radioanal. Lett.; 7: No. 5-6, 295-301(10 Sep 1971).

Methods were developed for checking the quality of analytical and suprapure reagents for Cl, As, Cu, Mn, and Na. A system for rapid evaporation of liquid samples under chemically sterile conditions is described. Activation analysis is shown to give suitable sensitivity and adequate precision for some very important contaminants at concentration levels in the range of 1 ng/ml and less. (auth)

57380 SUBSTOICHIOMETRIC DETERMINATION OF SELENIUM BY NEUTRON ACTIVATION ANALYSIS. Nadkarni, R. A.; Haldar, B. C. (Inst. of Science, Bombay). Radiochem. Radioanal. Lett.; 7: No. 5-6, 305-11(10 Sep 1971).

A method was developed for substoichiometric neutron activation analysis of trace amounts of selenium, based on extraction of Se(IV) with diaminobenzidine in ethyl acetate. The selenium content of the geological standard rocks T-1, W-1, Sye-1, and GR, as well as the meteorite Allende de Publito, and the biological standard kale, were determined by the proposed method. (auth)

57381 SUBSTOICHIOMETRIC DETERMINATION OF NICKEL IN STEEL BY NEUTRON ACTIVATION ANALYSIS. Doctor, Z. K.; Haldar, B. C. (Inst. of Science, Bombay). Radiochem. Radioanal. Lett.; 7: No. 5-6, 339-43(10 Sep 1971).

A rapid method for determination of traces of nickel in steel by neutron activation involving substoichiometric extraction of its dimethylglyoxime comples into chloroform is described. NBS steels, SRM 14e and SRM 10G, were analyzed for nickel by the proposed method and the results agree well with the values reported in the certificates of analyses. The time taken for radiochemical processing and counting is 15 min and the sensitivity of the method is 0.1 μg. (auth)

57382 EXPRESS DETERMINATION OF YTTRIUM IN RARE EARTH CONCENTRATES BY THE METHOD OF ACTIVATION WITH FAST NEUTRONS. Lisovskii, I. P.; Nikonov, V. N.; Smakhtin, L. A.; Sukhov, G. V.; Troyanker, L. M. (Physical-Chemical Inst., Moscow. State Scientific-Research and Design Inst. of the Rare Metal Industry, Moscow). Zh. Anal. Khim.; 26: No. 8, 1511-13(Aug 1971). (In Russian).

An express determination (2 to 4 min) of yttrium in yttroparasite concentrates is possible. The method was checked on synthetic mixtures and compared with the spectrographic emission method. The method can be used for the technological control of the industrial process. (auth)

57383 APPLICATION OF NEUTRON ACTIVATION ANALYSIS FOR THE DETERMINATION OF TRACE AMOUNTS OF BROMINE IN PULP. Johanson, M.; Fogelberg, B. C. Pap. Puu; 53: No. 5, 315-22(1971).

An examination has been made of the possibilities of the determination of bromine, and accordingly bromine-containing fungicides, in mechanical pulp and sulphite pulp by the application of direct spectrometric activation analysis. The samples were irradiated in a neutron flux in a reactor. The gamma radiation emitted by the samples was analyzed by means of a spectrometer, and the 0.55-MeV photopeak found to be a suitable basis for the quantitative determination of bromine. Experiments with known amounts of bromine showed the existence of a linear relation between the amount of bromine and the area under the 0.55-MeV photopeak. The experiments showed that minute amounts of bromine in mechanical pulp and sulphite pulp can be determined to an adequate degree of accuracy if correction is made for the background radiation of the sample. (Finland)

57384 ACTIVATION ANALYSIS OF SODIUM AND POTASSIUM IN SOLID PROPELLANTS. Barber, W. H. (Naval Ordnance Station, Indian Head, Md.); Dengel, O. H.; Vogt, R. H.; Strain, C. V. Nucl. Technol.; 12: No. 4, 381-7(Dec 1971).

Neutron activation analysis has been used to detect trace amounts of sodium and potassium in solid rocket propellants containing aluminum. The technique employs a water-pool reactor to irradiate the samples with thermal neutrons, and utilizes gamma spectroscopy to nondestructively analyze the samples for trace impurities. This technique permits precise and accurate determination of sodium and potassium in solid propellants containing as much as 20% aluminum. (auth)

57385 GAMMA-ACTIVATION METHOD FOR DETERMINING CARBON AND OXYGEN IN BERYLLIUM. Zadvornyi, A. S.; Gorenko, A. F.; Serykh, N. V.; Skakun, N. A.; Klyucharev, A. P. (Physical-Technical Inst., Kharkov). Zh. Anal. Khim.; 26: No. 9, 1841-3(Sep 1971). (In Russian).

The gamma-activation method permits a highly selective determination of 5×10^{-4} wt. % of carbon and oxygen in beryllium. There is no necessity to destroy the sample. The sensitivity can be essentially increased by decreasing the interference and increasing the gamma flux. (auth)

57386 NEUTRON ACTIVATION DETERMINATION OF COBALT BY NONDESTRUCTIVE MEANS. Lobanov, E. M.; Allabergenov, B. R.; Akbarov, U.; Nishanov, P. Kh. (Inst. of Nuclear Physics, Tashkent). Izv. Akad. Nauk Uzb. SSR, Ser. Fiz.-Mat. Nauk; No. 5, 87-8(1970). (In Russian).

A number of radioisotopes possess a gamma energy similar to that of ^{60}Co, and therefore interfere with the determination of the latter in a mixture. A method is described that uses an integrated coincidence spectrometer with a single-channel analyzer, passing only the total impulses from the ^{60}Co cascade radiation. In this way the Co activity was determined in samples of pyroxene, pyrite, and iron meteors after their irradiation in a reactor with a thermal flux of 1.8×10^{13} n/sec. over periods of from 1 to 10 hr. (K.S.W.)

57387 INSTRUMENTAL NEUTRON ACTIVATION ANALYSIS OF ROCKS WITH A LOW-ENERGY PHOTON DETECTOR. Hertogen, J.; Gijbels, R. (State Univ., Ghent). Anal. Chim. Acta; 56: No. 1, 61-82(Aug 1971).

The usefulness of a small low-energy photon Ge(Li) detector for instrumental neutron activation analysis of silicate rocks was investigated. In order to avoid systematic errors caused by self-absorption of low-energy photons and by the counting geometry, a sample pelletizing technique is proposed. The spectral interferences in spectra taken with the small Ge(Li) detector and with a large one were compared and a definite advantage for a small detector was found for the determination of Ce, Nd, Sm, Eu, Gd, Tb, Dy, Tm, Yb, Lu, Ta, and U. (auth)

57388 CONTINUOUS NEUTRON ACTIVATION ANALYSIS. Kliment, Vladimir; Toelgyessy, Juraj (Slovenska Vysoka Skola Technicka, Bratislava). Chem. Listy; 65: No. 8, 799-822 (1971). (In Slovak).

Practical applications of neutron activation analysis for continuous analytical control are reviewed. (61 references.) (auth)

57389 DETERMINATION OF IMPURITIES IN PYROGRAPHITE BY METHOD OF DELAYED COINCIDENCES OF β AND γ RADIATION. Lobanov, E. M.; Valieva, M. G.; Sadekov, Kh. M.; Usmanova, M. M. At. Energ. (USSR); 31: No. 3, 233-5(Sep 1971). (In Russian).

The trace elements La, Nd, Ta, and W were investigated in pyrographite by the activation method of the Nsec delay in β and γ coincidences. The device is based on delayed coincidence circuits and used for the identification of different nuclei according to their excited state in lifetimes in the range of 10^{-5} to 10^{-9} sec. The characteristic γ spectrum of the decay of the given nuclear isomeric level is the final product of analysis. $\beta-\gamma$ and $\gamma-\gamma$ coincidences were used in trace analysis of pyrographite. (auth)

57390 SYSTEM FOR AUTOMATED ONE-ELEMENT ACTIVATION ANALYSIS. Venkov, S. N.; Egiazarov, B. G.; Korytko, L. A. At. Energ. (USSR); 31: No. 3, 227-32(Sep 1971). (In Russian).

A system and programs for automated instrumental activation analysis are described. A structural circuit of the system and programs of its operation and data processing permit an automated analysis of irradiated samples to be carried out in various spectrometric modes: (1) according to a chosen spectral line of the induced gamma radioactivity; (2) by a method of "spectral ratios" according to two spectral lines, taking into account a "harder" line contribution to the measurement results obtained according to a "soft" line; (3) with separation of an activity investigated through a coincidence method, etc. The capabilities of the system are illustrated by measuring oxygen and nitrogen contents in various materials and in the presence of fission products. An instrumental sensitivity of the system for the oxygen analysis is ~10^{-3}% (a single analysis), when the neutron generator output is ~10^9 n/sec and sample weight is ~5 to 10 g. Reproducibility (apparatus error) of the measurement results during many-hour operation is not worse than ±0.7%. (auth)

57391 NEUTRON ACTIVATION ANALYSIS OF ENRICHED ISOTOPES OF EUROPIUM, INDIUM, IRIDIUM, AND LUTETIUM. Vasil'ev, S. S.; Abbosov, O.; Velyus, L. M.; Kodiri, S.; Starchik, L. P. At. Energ. (USSR); 31: No. 3, 285-7(Sep 1971). (In Russian).

Samples of Eu_2O_3, Lu_2O_3, Ir, and In_2O_3 were exposed to thermal neutrons, and the gamma spectra were examined with a scintillation counter. In order to determine the ratios between the gamma intensity and the content of a given isotope, the samples were enriched to various concentrations of those isotopes. Graphs are reproduced that portray the heights of the spectral peaks at various isotopic concentrations. Because the method of determination described is only relative, a standard must be irradiated together with each unknown sample. (K.S.W.)

57392 MERCURY IN THE ENVIRONMENT. de Goeij, J. J. M.; Houtman, J. P. W. (Interuniversity Reactor Inst., Delft, Netherlands). Chem. Weekbl.; 67: 13-20(5 Mar 1971). (In Dutch). (IRI-133-71-01).

A survey of some aspects of the mercury pollution problem is given. Mercury levels are presented for Dutch fish, shellfish, birds, waters, and sediments, as well as for imported canned fish. The mercury determination was performed by neutron activation analysis and automated chemical separations. (auth)

57393 APPLICATION OF AN ELECTROCHEMICAL PRECONCENTRATION TECHNIQUE TO NEUTRON ACTIVATION ANALYSIS OF TRACE METAL IONS. Mark, Harry B. Jr. (Univ. of Cincinnati). J. Pharm. Belg.; 25: 367-99(Sep-Oct 1970).

A method is described for the determination of trace metal ions that combines electrochemical separation and neutron activation analysis. Advantages of the method are selectivity combined with sensitivity, preconcentration advantages such as elimination of hot chemical separations, ease of use of short-lived nuclides, and ability to determine several species simultaneously. (D.H.M.)

57394 DETERMINATION OF SELENIUM IN GLACIAL ICE BY RADIOACTIVATION. Weiss, Herbert V. (Naval Undersea Research and Development Center, San Diego, Calif.). Anal. Chim. Acta; 56: No. 1, 136-9(Aug 1971).

An activation procedure was developed that allows the counting of samples within 12 to 14 min after irradiation and thereby effects a twofold increase in sensitivity over other activation methods. The samples were collected and stored in polyethylene containers. The samples were dissolved in nitric acid in a quartz flask and a ^{75}Se spike added. The solution was evaporated and the residual drop diluted in water and irradiated. A radiochemical purification process was carried out, selenium precipitated, and β particles counted. After counting the ^{75}Se γ activity was measured and compared with standards. The limit of sensitivity was less than 1 ng. (M.C.G.)

57395 NEUTRON ACTIVATION STUDIES OF THE ROANOKE RIVER SYSTEM. Furr, A. Keith; Mooney, Edward (Virginia Polytechnic Inst., Blacksburg. State Univ., Blacksburg, Va.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 79-85(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A study of an unusually compact and well-defined river system containing many environmental factors leading to water pollution has been carried out by neutron activation analysis. Detailed baseline measurements of the levels of sodium, chlorine, magnesium, manganese, calcium, strontium, and aluminum were made and tests made above and below major effluent sources. (auth)

57396 USE OF (p,γ) REACTION TO DETERMINE LIGHT-ELEMENT CONTENT IN THIN SURFACE LAYERS. Vasil'ev, S. S.; Dzhemard'yan, Yu. A.; Mikhailov, G. I.; Starchik, L. P. At. Energ. (USSR); 30: No. 4, 397-8(Apr 1971). (In Russian).

Following earlier studies concerning the identification of light elements in thin surface layers by the (p,γ) reaction, an expression was derived to determine the highest yield of the reaction. Actual analytical application of the method was studied by determining the contamination by carbon of 8 semiconductor-grade silicon specimens at various stages of fabrication, such as cutting and polishing. An electrostatic accelerator was used to accelerate the protons. The carbon content was determined on the basis of the $^{12}C(p,\gamma)^{13}N$ reaction, with $T_{1/2} = 10.1$ min, $E_{\beta^+} = 1.19$ MeV and $E_\gamma \approx 2.4$ MeV. The problem was solved by examining the excitation functions of silicon, carbon, and tantalum, obtained by the irradiation of the corresponding targets; the contamination of silicon with carbon was calculated by comparing the data with the reference specimen, and Si sample containing 0.1% C. The actual contamination was obtained by calculation or by comparison of the γ and β^+ yields of the $^{12}C(p,\gamma)^{13}N$ reaction. (TTT)

57397 (IN-1475) FIRST PRODUCT DENITRATION CAMPAIGN WITH ENRICHED URANIUM AT ICPP. Bjorklund, W. J.; Offutt, G. F. (Idaho Nuclear Corp., Idaho Falls). Jun 1971. Contract AT(10-1)-1230. 26p. Dep. NTIS.

Highly enriched uranium in the form of uranyl nitrate solution was converted to uranium trioxide in a fluidized bed denitration process at the Idaho Chemical Processing Plant. Information is presented relative to the first successful denitration campaign in which nearly 800 kg of uranium were denitrated. (auth)

57398 (NIM-1093) CALCULATION OF THE EQUILIBRIUM DISTRIBUTION OF METAL-ION COMPLEXES IN MULTICOMPONENT AQUEOUS SYSTEMS. Needes, C. R. S. (National Inst. for Metallurgy, Johannesburg (South Africa)). 23 Nov 1970. 18p. Dep. NTIS (U. S. Sales Only).

A computer program based on the generalized Newton-Raphson iterative method to solve n nonlinear implicit polynomial equations was developed to calculate the equilibrium distribution of metal-ion complexes in a multicomponent system. The method is suited to solution of a group of equations where separation of the variables is either impossible or leads to unwieldy polynomial expressions. The solutions of the three-component system $UO_2^{2+}-CO_3^{2-}-OH^-$, the four-component system $UO_2^{2+}-Fe^{3+}-SO_4^{2-}-OH^-$ and the six-component system $Cu^{2+}-Zn^{2+}-Fe^{3+}-Fe^{2+}-OH^--SO_4^{2-}$ are provided. (auth)

57399 (NIM-1144) THREE-DIMENSIONAL PREDOMINANT-AREA AND SOLUBILITY DIAGRAMS FOR THE URANYL CARBONATE AND URANYL SULPHATE SYSTEMS AT 25°C. Needes, C. R. S. (National Inst. for Metallurgy, Johannesburg (South Africa)). 4 Jan 1971. 24p. Dep. NTIS (U. S. Sales Only).

The equilibrium distribution of species in the systems $UO_2^{2+}-CO_3^{2-}-OH^-$ and $UO_2^{2+}-SO_4^{2-}-OH^-$ at 25°C was calculated by use of a computer program. The calculations were based on stability constant data taken from the literature and applied to the following conditions: total uranium concentrations of 10^{-6} to 10^{-1} M, total ligand concentrations of 10^{-4} to 10 M, and pH values between -2 and 14. The data for each of the systems were condensed into three dimensional diagrams representing the fields of predominance and solubility of the various ionic and solid species considered. (auth)

57400 PLUTONIUM(V) PEROXIDE. Musikas, C. (CEA, Fontenay-aux-Roses, France). Radiochem. Radioanal. Lett.; 7: No. 5-6, 375-9(10 Sep 1971). (In French).

Spectrophotometric evidence is given for Pu(V) peroxide formation in alkaline medium. In this medium Pu(VI) ions are reduced to Pu(V) ions. The Pu(V) peroxide is soluble and less stable than the corresponding Np(V) complex. It could be observed only at low temperature. (auth)

57401 EFFECT OF SOME RARE ELEMENTS ON NITRIFICATION BY NITRATE-FORMING BACTERIA IN SOIL SUSPENSION. Tandon, S. P.; Mishra, M. M. (Univ. of Allahabad, India). Zentralbl. Bakteriol. Parasitenk., Abt. II; 122: 155-7 (1968).

The effect of thallous sulfate, beryllium sulfate, indium sulfate, thorium sulfate, auric chloride, uranyl sulfate, and zirconium chloride on nitrate formation by Nitrobacter agilis in the soil suspension was studied and it was found that except for thallous sulfate and auric chloride, the presence of all other rare salts, accelerates the rate of nitrate formation. The rate is retarded in the presence of thallous sulfate and auric chloride. (auth)

57402 STABILITY CONSTANTS OF URANYL ION WITH MIXED CARBOXYLIC ACIDS. Ramamoorthy, S.; Balakrishnan, M. S.; Santappa, M. (Univ. of Madras). J. Inorg. Nucl. Chem.; 33: No. 8, 2713-16(Aug 1971).

A curve is given representing the titration of the mixed complex against sodium hydroxide for the uranyl ion-p-hydroxybenzoic acid–phenylacetic acid. The formation of the mixed complex of this acid was inferred from the qualitative evidence that precipitation of the system occurred at pH 5.73, while the uranyl ion–p-hydroxybenzoic acid system precipitated at pH 5.02, and uranyl ion–phenylacetic acid system precipitated at pH 5.42. The composition of the mixed complex was assumed to be 1 : 1 : 1 since neither p-hydroxybenzoic nor phenylacetic acid when titrated separately with U^{6+} tended to form complexes higher than 1 : 1. Formation of the mixed complex of uranyl ion–p-hydroxybenzoic acid–phenylacetic acid by simultaneous equilibrium was inferred from titration curves and hence the stability constant of the complex was calculated. In systems such as uranyl ion–benzoic acid–p-hydroxybenzoic acid where the precipitation point of the mixed system is in between those of the individual systems, the mixed system is found to precipitate only once and the formation of only one species was indicated. Stability constants were similarly evaluated for other uranyl complexes formed with carboxylic acids. (UK)

57403 PRECIPITATION OF SOME ACTINIDE ELEMENT COMPLEX IONS BY USING HEXAMMINE COBALT(III) CATION. III. THE PRECIPITATION OF NEPTUNIUM(VI) AND AMERICIUM(VI) SULFATE COMPLEX IONS WITH HEXAMMINE COBALT (III) CATION. Ueno, Kaoru; Hoshi, Michio. J. Inorg. Nucl. Chem.; 33: No. 8, 2631-3(Aug 1971).

The crystalline compounds $\{[Co(NH_3)_6]HSO_4\}_2[NpO_2(SO_4)_3] \cdot nH_2O$ and $\{[Co(NH_3)_6]\ HSO_4\}_2[AmO_2(SO_4)_3] \cdot nH_2O$ were prepared by addition of hexammine cobalt(III) ion to an aqueous solution of MO_2^{2+}. They are isostructural with $\{[Co(NH_3)_6]HSO_4\}_2[UO_2(SO_4)_3] \cdot 5H_2O$: cubic symmetry of the diamond type, with lattice constant a = 10.74 Å for both neptunium and americium compounds. Absorption spectra for neptunium(VI), plutonium(VI), and americium(VI) compounds in dilute sodium carbonate solution are also presented. (auth)

57404 HEPTAVALENT STATE OF NEPTUNIUM AND PLUTONIUM. Krot, N. N.; Gel'man, A. D.; Mefod'eva, M. P. Vestn. Akad. Nauk SSSR; No. 3, 57-61(Mar 1970). (In Russian).

Np(VII) is obtained by passing ozone through a suspension of sodium neptunate in alkaline medium. The intense green solution obtained has an absorption maximum at 412 and 625 nm. Pu(VII) is obtained in an analogous fashion. The heptavalent state was confirmed by spectrophotometric titration with a reducing agent. A list of other suitable oxidizing agents for producing Np(VII) or Pu(VII) is offered. Potentials of the VII/VI half cells were given as 0.6 V for Np and between 0.8 and 1.1 V for Pu. Np(VII) compounds are stable in the solid state, but Pu(VII) compounds gradually undergo a transition to the hexavalent state. Other features of the heptavalent states of these two elements are discussed in connection with other chemical reactants. (K.S.W.)

57405 SODIUM URANATES: PREPARATION AND THERMOCHEMICAL PROPERTIES. Cordfunke, E. H. P.; Loopstra, B. O. (Reactor Centrum Nederland, Petten). J. Inorg. Nucl. Chem.; 33: No. 8, 2427-36(Aug 1971).

The preparation and thermal stability of the various phases in the sodium uranate system, in which uranium has the valency of both VI and V, are described. X-ray powder data and heats of formation are given. (auth)

57406 INTERACTION OF SILICIC ACID WITH IRON(III) AND URANYL IONS IN DILUTE AQUEOUS SOLUTION. Porter, Richard A.; Weber, Walter J. Jr. (Univ. of Michigan, Ann Arbor). J. Inorg. Nucl. Chem.; 33: No. 8, 2443-9(Aug 1971).

The interaction of iron(III) and uranyl ions with dissolved silica was studied by a spectrophotometric technique. The interaction with iron was studied as a function of the degree of polymerization of the silica. For uranyl ion, a complex with monomeric silica was inferred. An equilibrium constant $pQ_1 \sim 2.0$ for the equilibrium $UO_2^{2+} + Si(OH)_4 = UO_2SiO(OH)_3^{+} + H^+$ was measured. (auth)

57407 THERMAL DECOMPOSITION OF HYDROUS OXIDE AND OXYCARBONATE OF THORIUM. Saito, Yasutoshi (Akita Univ., Japan). Funtai Oyobi Funmatsuyakin; 17: No. 7, 295-9(Apr 1971). (In Japanese).

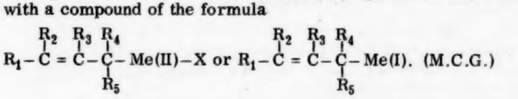
Thermal decomposition of the hydrous oxide and oxycarbonate of thorium was studied by thermogravimetry (TG), differential thermal analysis (DTA), and Hahn's emanation technique. The hydrous oxide was precipitated from a thorium salt solution by the addition of hydroxide ion. TG curves showed that the hydrous oxide gradually lost water and did not suffer from a step-by-step dehydration. DTA curves showed an endothermic peak around 150°C followed by a small exothermic peak at 250° to 300°C. In emanation curves two prominent peaks were observed, one corresponding to the 150°C peak in DTA, and the other centered at 400° to 450°C. The endothermic peak in DTA and two emanation peaks were presumed to be due to the escape of adsorbed or occluded water, and the exothermic peak in DTA due to the crystallization of the amorphous hydrous oxide. The hydrous oxide might not be hydroxide nor oxide hydrated but aquated oxide. The hydrous oxycarbonate lost water rapidly to about 200°C on heating, resulting in the formation of $ThOCO_3 \cdot H_2O$, and then followed by less rapid decomposition to the oxide. In the electron microscope, the oxide particles prepared from the hydrous oxide and oxycarbonate were irregular in the shape of agglomerates of fine primary particles. (auth) (Japan)

57408 π-ALLYL COMPOUNDS OF URANIUM. (to Snam Progetti SpA). British Patent 1,246,424. 15 Sep 1971. Priority date 2 May 1969, Italy.

A method is described for preparation of allyl compounds of uranium having the same general formula:

$$\left[R_1-\overset{R_2}{\overset{|}{C}}\!=\!\overset{R_3}{\overset{|}{C}}\!=\!\overset{R_4}{\overset{|}{C}}-R_5\right]_4U.$$

A suspension of a tetravalent uranium in a polar solvent is reacted with a compound of the formula



$$R_1-\overset{R_2}{\overset{|}{C}}=\overset{R_3}{\overset{|}{C}}-\underset{R_5}{\underset{|}{\overset{R_4}{\overset{|}{C}}}}-Me(II)-X \text{ or } R_1-\overset{R_2}{\overset{|}{C}}=\overset{R_3}{\overset{|}{C}}-\underset{R_5}{\underset{|}{\overset{R_4}{\overset{|}{C}}}}-Me(I).$$

(M.C.G.)

57409 COPRECIPITATION OF URANIUM WITH CALCIUM CARBONATE. Kitano, Yasushi; Oomori, Tamotsu (Nagoya Univ., Japan). Nippon Kaiyo Gakkaishi; 27: No. 1, 34-42(Feb 1971).

A study of the factors controlling the trace element content of marine calcareous skeletons is reported. The values of the distribution coefficients of UO_2^{2+} between solutions and carbonate precipitates were measured in the laboratory at 20 ± 1°C. From the determination of the uranium contents of marine calcareous skeletons and seawater, the values of uranium between marine calcareous skeletons and seawater are expected as 1.2 to 0.3 for aragonite and 0.2 to 0.0n for calcite. The experimentally measured value of the distribution coefficient for aragonite is thermodynamically discussed. The value of the distribution coefficient of UO_2^{2+} is controlled greatly by the activity coefficient of uranium dissolved in a parent medium and the crystal form of $CaCO_3$. The activity coefficient of uranium in solution is due mainly to the formation of complexes between UO_2^{2+} and CO_3^{2-} in the solution. (auth) (Japan)

57410 INFLUENCE OF IRON ON THE PHYSICOCHEMICAL STATE OF RADIOELEMENTS IN SEA WATER. Bernovskaya, R. N.; Bogdanov, Yu. A.; Gromov, V. V.; (and others). Sov. Radiochem. (Engl. Transl.); 13: No. 1, 158-60(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 157-9(Jan-Feb 1971).

The state of iron in seawater as a function of the pH of the medium was investigated with the aid of the isotope ^{55}Fe. It was shown that ^{144}Ce, ^{91}Y, and ^{95}Nb can be effectively extracted from seawater by the hydrolysis products of iron (coprecipitation), or they are sorbed on the surface of ferric hydroxide. It was hypothesized that iron, being an important biogenic element, can promote the involvement of a number of radionuclides in biological circulation. (auth)

57411 INDUCED REACTIONS IN RADIOCHEMISTRY. V. CONDITIONS DETERMINING THE REACTION YIELD IN A CLOSED SYSTEM. Posvol'skii, M. V.; Tsirlin, I. I. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 58-62(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 63-8(Jan-Feb 1971).

The dependence of the yield of the induced reaction on the initial conditions and values of the rate constants of the competing reactions of the intermediate compounds was considered in general form. It was shown theoretically that for each acceptor the inducers are divided into two groups: for the first group a 100% yield is achieved only at an infinite consumption of the inducer, and for the second at a finite consumption. The boundary between the groups lies at a value of the parameter n = 0. The results of the theoretical analysis agree with the experimental data. (auth)

57412 HEPTAVALENT STATE OF THE TRANSURANIUM ELEMENTS. XII. THE OXIDATION OF NEPTUNIUM(VI) BY POTASSIUM PERSULFATE. Shilov, V. P.; Krot, N. N.; Gel'man, A. D. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 7-11 (Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 9-14(Jan-Feb 1971).

The oxidation of neptunium(VI) to the heptavalent state by potassium persulfate at 50 to 70°C was studied in solutions with a sodium hydroxide concentration of 0.1 to 8 M. Neptunium(VI) is almost

XUM

entirely oxidized in 0.1 to 0.9 M NaOH. The reaction rate is first order with respect to persulfate. The activation energy is 33.5 l kcal/mole ($\mu = 1$ and $[OH^-] = 0.7$ g-ion/liter). The reaction is accelerated by the addition of silver, nickel, and cobalt at the level $(2-5) \cdot 10^{-6}$ M. (auth)

57413 INDUCED REACTIONS IN RADIOCHEMISTRY. VI. CONDITIONS DETERMINING THE REACTION YIELD IN AN OPEN SYSTEM. Posvol'skii, M. V.; Tsirlin, I. I.; Kochnov, V. A. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 63-6(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 68-71(Jan-Feb 1971).

The yield of an induced reaction in an open system is a function of the initial conditions, Q_I/Q_C. The influence of other factors is superimposed on this basic dependence: the initial concentration of the actor, the rate of its interaction with the inducer, the total concentration of all the components, the rate of introduction of the inducer, and its concentration in the delivered solution. The yield of an induced reaction in an open system in the case of gradual introduction of the inducer is always higher than the yield of this reaction in a closed system. (auth)

57414 INTERACTION OF NEPTUNIUM WITH HYDROGEN PEROXIDE IN CONCENTRATED SOLUTIONS OF NITRIC ACID. Krot, N. N.; Shuiskaya, L. G. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 73-7(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 79-83(Jan-Feb 1971).

Neptunium(V) in 6 to 8M HNO_3 is reversibly oxidized to neptunium(VI) and irreversibly reduced to the tetravalent state. The rate of the reversible oxidation of neptunium(V) is substantially higher than the rate of its reduction. As a result, after some period of time, the stationary equilibrium $[Np(VI)] = K_0\ [NP(V)]$, is established in solution, and does not depend on the neptunium and H_2O_2 concentrations. The value of the constant of this equilibrium at 20°C and $[HNO_3] = 7.5$ M equals 1.8 ± 0.4. After the establishment of stationary equilibrium, the rate of reduction of neptunium to the tetravalent state is described by the equation of a first order reaction with respect to the metal and first order with respect to H_2O_2. The value of the constant K at 20°C and a HNO_3 concentration of 7.5 M is (9.3 ± 0.3) liters/mole · min. The value of K decreases with decreasing HNO_3 concentration. The temperature dependence of K corresponds to a value of the activation energy of the reduction process equal to 13.2 ± 0.5 kcal/mole ($[HNO_3] = 7.5$ M). (auth)

57415 REDUCTION OF THE URANYL ION BY TITANIUM(III) IN NONAQUEOUS MEDIA. Belyaev, Yu. I.; Vdovenko, V. M.; Skoblo, A. I.; Suglobov, D. N. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 137-9(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 140-2(Jan-Feb 1971).

The reaction of $(C_{10}H_{21})_4NUO_2Cl_3$ with $TiCl_3$ was investigated in various solvents (dimethylformamide, methanol, TBP, acetone, acetonitrile), and its stoichiometry was established. It was shown that in all the media studied at 20° there is a rapid reduction of UO_2^{2+} to U^{4+}, with the formation of TiO^{2+} and UCl_6^{2-} (dimethylformamide, acetonitrile), UCl_5^- (TBP, acetone), and UCl_4 (methanol). The reaction products were identified by ir and visible spectra. The high reaction rate and the absence of influence of the solvent support its "intrasphere" mechanism, in which there is a direct contact of the coordination spheres of U(VI) and Ti(III) in the process of transfer of an electron and oxygen. (auth)

57416 FORMATION OF HYDRATES OF URANIUM(VI), GADOLINIUM, AND TERBIUM PEROXIDES UNDER THE ACTION OF ULTRAVIOLET LIGHT. Dobrolyubskaya, T. S. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 140-3(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 143-6(Jan-Feb 1971).

Changes in the luminescence and absorption spectra of dilute sulfuric acid solutions of uranium(VI), gadolinium, and terbium were studied in the case of prolonged irradiation with ultraviolet light. As a result of the influence of light, an impurity of hydrates of peroxide compounds is formed in the solutions, and the tendency for their formation is most pronounced for gadolinium, less for uranium, and to a very negligible degree for terbium. The mechanism of the photochemical process is discussed. (auth)

57417 INTERACTION OF AMORPHOUS URANIUM TRIOXIDE WITH CARBON MONOXIDE. Bessonov, A. F. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 147-9(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 148-50(Jan-Feb 1971).

Data on the reaction were obtained with a high-temperature x-ray camera and complex dilatometric apparatus. The conversions that occur in the reduction of amorphous UO_3 by CO can be depicted by the following scheme: $UO_{3(am)} \rightarrow U_3O_{8(tx)}^{hex} \rightarrow U_4O_9 \rightarrow UO_{2+x} \rightarrow UO_2$. (M.C.G.)

57418 COPRECIPITATION OF RADIUM WITH A PROTOTYPE OF THE BONE MINERAL CALCIUM HYDROXYLAPATITE. Popov, D. K.; Mikhailova, A. I.; Basalaeva, L. N. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 150-2(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 151-3(Jan-Feb 1971).

The coprecipitation of radium with recrystallized calcium hydroxylapatite (an analog of bone mineral) is entirely due to isomorphous cocrystallization. The distribution of radium is very close to the distribution of strontium and barium. The solid phase is impoverished in microcomponents with respect to calcium. Like barium, radium coprecipitates more completely than strontium with fresh portions of hydroxylapatite. It is suggested that the increased trapping of barium and radium by fresh precipitates is explained by their volume coprecipitation with the precrystalline calcium phosphate present in fresh precipitates of hydroxylapatite and representing an analog of the exchange component of the bone mineral. In such a case the lower retention of the radioactive isotopes of barium and radium by the organism in comparison with the retention of strontium isotopes is probably due to the fact that the heavy elements of the alkaline earth group are primarily concentrated in the rapidly exchanged component of the bone mineral. (auth)

57419 PREPARATION OF ANHYDROUS URANIUM TETRACHLORIDE AND MEASUREMENTS ON ITS MAGNETIC SUSCEPtibility. Yoshimura, Tetsuhiko; Miyake, Chie; Imoto, Shosuke (Osaka Univ.). J. Nucl. Sci. Technol. (Tokyo); 8: No. 9, 498-502(Sep 1971).

The reaction of UO_2 with CCl_4 vapor was carried out in a vacuum of 10^{-5} mmHg at 500°C in order to prepare UCl_4 of high purity. The lattice parameters were calculated from x-ray analysis to be $a_0 = 8.278 \pm 0.002$, $c_0 = 7.460 \pm 0.009$. The product thus obtained was verified by chemical and x-ray analyses to be of anhydride form. The magnetic susceptibility was measured over the temperature range from liquid N_2 to liquid He temperature, which revealed a deviation from the straight $1/\chi - T$ relation toward lower temperature. (auth)

57420 ELECTROCHEMISTRY OF Pu(III) IN MOLTEN LiCl–KCl EUTECTIC. Martinot, L.; Duyckaerts, G. (Lab. of Nuclear Chemistry, Liege). Anal. Lett.; 4: No. 1, 1-11 (Jan 1971).

A chronopotentiometric study of the reactions Pu(III) → Pu(IV) + e^- in molten LiCl–KCl eutectic is reported. The diffusion coefficient $D_{Pu(III)}$ increased from $4.8 \cdot 10^{-6}$ to $27.6 \cdot 10^{-6}$ $cm^2\ sec^{-1}$ when the temperature was raised from 400 to 650°C. An estimate of the activation energy of the electrochemical reaction is also reported. (auth)

Isotope Effects and Exchange

57421 INFRARED BANDS OF $H^{12}C^{15}N$, $D^{12}C^{15}N$, AND $H^{13}C^{15}N$. Alpert, B. D.; Mantz, A. W.; Rao, K. Narahari (Ohio State Univ., Columbus). J. Mol. Spectrosc.; 39: No. 1, 159-62(Jul 1971).

Infrared spectra of some of the isotopic varieties of the hydrogen cyanide molecule were measured employing high precision vacuum grating spectrographs. Several bands of $H^{12}C^{15}N$, $D^{12}C^{15}N$, and $H^{13}C^{15}N$ occurring in the 2 to 7 μ region are reported for the first time. Molecular constants were derived from these data. (auth)

57422 NORMAL COORDINATE ANALYSIS OF ETHYL CHLORIDE AND SOME DEUTERATED DERIVATIVES. Dempster, A. B.; Zerbi, G. (Istituto di Chimica delle Macromolecole, Milan). J. Mol. Spectrosc.; 39: No. 1, 1-7(Jul 1971).

A recently published force field for alkyl chlorides was slightly refined as a result of normal coordinate analysis calculations to fit the vibrational spectra of ethyl chloride-d_0, -d_2, -d_3, and -d_5. In doing so it was possible to clarify some problems raised in previous work concerning the experimental bands to be ascribed to fundamentals and to obtain a quantitative description of the normal modes. (auth)

57423 ROTATIONAL CONSTANTS FOR HCN AND DCN. Winnewisser, Gisbert (National Research Council, Ottawa); Maki, Arthur G.; Johnson, Donald R. J. Mol. Spectrosc.; 39: No. 1, 149-58(Jul 1971).

Microwave measurements of rotational transitions within vibrationally excited states of several isotopic species of HCN have given improved values for the pertinent B_v constants. These new data have been combined with infrared measurements given in the literature (including D_v terms) to arrive at a set of rovibrational constants (α and γ constants) which is consistent with all available data. Bond distances resulting from several different B_e approximations are intercompared to assess the variability of the r_e values and the importance of the γ terms. The latest r_0 and r_s bond distances are also given. (auth)

57424 ROTATIONAL SPECTRA OF NH_3 AND ND_3 IN THE 0.5-mm WAVELENGTH REGION. Helminger, Paul; De Lucia, Frank C.; Gordy, Walter (Duke Univ., Durham, N. C.). J. Mol. Spectrosc.; 39: No. 1, 94-7(Jul 1971).

Rotational transitions of NH_3 and ND_3 in the 0.5-mm wavelength region were observed and measured by microwave techniques. For ND_3 the two inversion components of the $J = 1 \rightarrow 2$ transitions of $^{14}ND_3$ and $^{15}ND_3$ at 0.49-mm wavelength were measured, and for NH_3 the $J = 0 \rightarrow 1$ transitions of $^{14}NH_3$ and $^{15}NH_3$ at 0.52-mm wavelengths have been remeasured with higher precision. With $J = 0 \rightarrow 1$ transition frequencies for ND_3 from previous microwave measurements and with the centrifugal stretching constant D_J for NH_3 measured in the infrared region, these frequencies yield the following spectral constants (in Mc/sec): for $^{14}ND_3$, $B_0 = 154\ 173.38$, $D_J = 5.91$, $D_{JK} = -10.49$; for $^{15}ND_3$, $B_0 = 153\ 600.97$, $D_J = 5.92$, $D_{JK} = -10.54$; for $^{14}NH_3$, $B_0 = 298\ 115.37$; and for $^{15}NH_3$, $B_0 = 297\ 388.12$. The effective ground-state structural dimensions for NH_3 are $d_{NH} = 1.0156$ Å and $<HNH = 107°17'$, and the corresponding values for ND_3 are $d_{ND} = 1.0143$ Å and $<DND = 107°4'$. Various substitution structures are also calculated. (auth)

57425 HMO ESTIMATION OF IODINE EXCHANGE RATES BETWEEN SUBSTITUTED ARYL IODIDES AND ALKALI IODIDES. Spevacek, V. (Inst. of Nuclear Research, Rez, Czech.). Radiochem. Radioanal. Lett.; 7: No. 5-6, 367-74(10 Sep 1971).

A procedure is described for estimation of isotope exchange rates between substituted aryl iodides and inorganic iodides, from localization energies (ΔW) calculated on the basis of the Hückel MO theory. The following correlation was found between the second order rate constants ($l \cdot mol^{-1}\ s^{-1}$) at 195°C and the localization energy: $\log k \pm 1.0 = -22.7\ \Delta W + 80.0$. The effect of electrolytic dissociation on the rate in organic solvents is discussed. (auth)

57426 ORDERING OF CARBON–HYDROGEN BOND STRENGTHS USING ISOTOPE EFFECTS. Lewis, Edward S.; Butler, Murdock M. (Rice Univ., Houston, Tex.). J. Chem. Soc., D; No. 16, 941-2(25 Aug 1971).

Variations in the tritium isotope effects in the radical addition of R^1SH to $R^2R^3C{=}CH_2$ are interpreted in terms of the transition state symmetry, measured by the difference in bond strengths to hydrogen in the initial state ($R^1S{-}H$) and the final state ($H{-}CR^2R^3CH_2SR^1$). (auth)

57427 DEUTERIUM SOLVENT ISOTOPE EFFECTS IN METHANOL SOLUTION. PART I. FRACTIONATION FACTORS FOR LYONIUM AND LYATE IONS. Gold, V.; Grist, S. (King's Coll., London). J. Chem. Soc., B; No. 8, 1665-70(1971).

The deuterium fractionation factors $[(D/H)_{solute}/(D/H)_{solvent}]$ for hydroxylic positions were determined by the nmr method for the methanolic hydrogen ion (0.62_5) and the methanolic methoxide ion (0.74). The effect of counterions was taken into account in the evaluation of fractionation factors. The existence of significant hydrogen isotope fractionation involving distinguishable hydroxylic positions created by the dissolution of sodium methoxide in methanol is consistent with other evidence for hydrogen-bonding solvation of lyate ions. The deuterium isotope effect on the ionic product of methanol (K_H/K_D) is calculated to be ca. 6.3. (auth)

57428 ISOTOPE EFFECT STUDY IN CATALYTIC EXCHANGE OF ETHANE. Guczi, L.; Sarkany, A.; Tetenyi, P. (Inst. of Isotopes, Budapest). Z. Phys. Chem. (Frankfurt); 74: No. 1-2, 26-31(1971).

Catalytic hydrogen exchange was studied between ethane and deuterium- as well as tritium-labeled hydrogen on nickel catalyst. A comparison of the ratio of the initial rates obtained by using tritium- and deuterium-labeled hydrogen to that of tritium to deuterium in hydrogen gas showed that there is no kinetic isotope effect with respect to the hydrogen isotopes. The simultaneous investigation of $H_2{-}D_2$ exchange on the same catalyst shows that the rate of $H_2{-}D_2$ conversion is much higher than that of hydrogen exchange in ethane; therefore, the experimental fact found for the kinetic isotope effect by using heavy and light hydrocarbons is correct and it is not influenced by the difference in the bond strength between Ni–H and Ni–D. (auth)

57429 PROTON MAGNETIC RESONANCE STUDY ON LIGHT- AND HEAVY-WATER SOLUTIONS OF Be(II). Farkas, A.; Tataru, E. Stud. Univ. Babes-Bolyai, Ser. Phys.; 16: No. 1, 79-81(1971).

The presence of deuterium in an aqueous solution of Be(II) evokes a change in the proton magnetic resonance spectrum under high resolution. Isotopic effects are evident, arising in the width of the signal within the temperature range 17.5 to 70°C. It appeared that the total sphere of hydration was richer in protons than free water. Isotopic chemical displacements were used for ionic complexes. The values are proportional to the concentration of deuterium and arranged in the direction of the weaker field. (tr-auth)

57430 RELATIVE TRITIUM–DEUTERIUM ISOTOPE EFFECTS IN THE ABSENCE OF LARGE TUNNELING FACTORS. Stern, Marvin J.; Vogel, P. Christian (Yeshiva Univ., New York). Contract AT(30-1)-3663. J. Amer. Chem. Soc.; 93: No. 19, 4664-75(22 Sep 1971).

Model calculations are used to investigate relative tritium–deuterium kinetic isotope effects and their temperature dependences. It is shown that, in the harmonic approximation and in the absence of large tunneling factors, relative effects, defined as $r = \ln(k_H/k_T)/\ln(k_H/k_D)$, are generally restricted to the range $1.33 \leq r \leq 1.58$, within the temperature interval 20 to 1000°K, provided that the individual tritium and deuterium effects are themselves reasonably large, in the normal direction ($k_{light} > k_{heavy}$), and exhibit "regular" temperature dependences at all temperatures. Overall, however, deviations from this range should not be rare. The extent of deviation usually increases with the degree of irregularity of the temperature dependences (temperature-dependence "anomalies") of the individual tritium and deuterium isotope effects. In addition, inverse isotope effects, even those with regular temperature dependences, will usually exhibit ill-behaved relative isotope effects because of the omnipresence in such cases of higher temperature "inversions," where the signs of $\ln(k_H/k_{D(T)})$ change from negative to positive. The relative isotope effect can start to reflect the presence of an inversion or anomaly in the individual effect(s) several hundred degrees away from the inversion temperature or anomalous region. The results of this study, when combined with the results of previous studies of the temperature dependences of individual isotope effects, indicate that the usual estimates of r may be used reliably to calculate deuterium isotope effects from measured tritium effects, or vice versa, only with sizable magnitude, pure primary, normal direction individual isotope effects and mixed primary–secondary normal direction individual isotope effects of sufficiently large magnitudes to be principally manifestations of the primary substitutions. Similarly, deviant values of relative tritium–deuterium isotope effects may be used to investigate factors such as quantum mechanical tunneling only under the same conditions. Fortunately, these are the conditions most likely to be involved in a study of tunneling. (auth)

57431 MANDELALDEHYDE–2-HYDROXYACETOPHENONE ISOMERIZATION. Griffiths, David W.; Gutsche, C. David (Washington Univ., St. Louis). J. Amer. Chem. Soc.; 93: No. 19, 4788-94(22 Sep 1971).

As a model system for gaining information about glyceraldehyde–dihydroxyacetone isomerization, the interconversion of mandelaldehyde and 2-hydroxyacetophenone was studied. Using mandelaldehyde and deuteriomandelaldehyde, isolated and added to the reaction mixture in the form of the dimers, with anhydrous pyridine and aqueous pyridine (H_2O and D_2O) as the basic catalyst, evidence was adduced to support the generally accepted enolization mechanism for the isomerization. The rate of the reaction shows a dependence on protic species, including the substrates and products themselves and is in accord with the expression rate = $(\Sigma k_i[HA]_i)$ [mandelaldehyde dimer] [pyridine]. A deuterium isotope effect of ca. 1.3 is observed which, when corrected for the apparently differing amounts of aldehyde form in equilibrium with the proteo dimer and the deuterio dimer, gives a value of ca. 3.9. From the rates of isomerization of p-methoxy-, p-methyl-, p-chloro-, and p-trifluoromethylmandelaldehyde (used as the dimers) a Hammett ρ constant of 1.4 ± 0.1 is calculated. The observed rates with trifluoroethanol, 2-pyridone, phenol, 2-hydroxymethylpyridine, 2-(β-hydroxyethyl)pyridine, 2-(γ-hydroxypropyl)pyridine, and benzoic acid indicate a Brønsted catalytic constant of 0.11 to 0.15 if the difference in pK_a values between water and pyridine solution is taken into account. Benzamidine was found to be a very much more effective catalyst than other bases of comparable basicity or other acids of comparable or greater acidity. Although these data do not allow a clean choice between the ring-opening step and the enolization step as the rate-determining event, the latter is considered to be more likely and is thought to require both a base (i.e., pyridine) and an acid (e.g., a protic species) catalyst. 57432 MECHANISM OF A RATE-CONTROLLED CROSS-DISPROPORTIONATION BETWEEN PHENOXYL RADICALS.

XUM

Adam, Waldemar; Chiu, Wen Tzong (Univ. of Puerto Rico, Rio Piedras). J. Amer. Chem. Soc.; 93: No. 15, 3687-93(28 Jul 1971).

The reaction of galvinoxyl with trihydrogalvinoxyl leads to hydrogalvinoxyl in the stoichiometric proportions of 2 : 1 : 3, respectively. The experimental rate law, measured by following the decay of the galvinoxyl ESR signal, was found to be second order in galvinoxyl, first order in trihydrogalvinoxyl, and inverse order in hydrogalvinoxyl. The activation parameters were $\Delta H^\ddagger$ = 7.7 kcal/mole and $\Delta S^\ddagger$ = −42.8 gibbs/mole, indicating that steric congestion is the principal factor in the rate-limiting step. The isotope effect for hydrogen transfer from carbon to oxygen was found to be 3.6, but no isotope effect for hydrogen transfer from oxygen to oxygen was observed. This implies that the methylene hydrogen of trihydrogalvinoxyl rather than the hydroxyl hydrogen is transferred in the slow step. Although the free energy of activation and thus the rates of hydrogen transfer were constant in a large number of diverse solvents, it was found that $\Delta H^\ddagger$ and $\Delta S^\ddagger$ for the hydrogen transfer in benzene, acetone, acetonitrile, and cyclohexane followed a linear relationship with an isokinetic temperature of 293.8°K. The mechanism is discussed in terms of initial fast reversible oxygen−oxygen hydrogen transfer between galvinoxyl and trihydrogalvinoxyl, followed by rate-controlled cross-disproportionation between galvinoxyl (G) and the dihydrogalvinoxyl (GH_2) radical. (auth)

57433 ENERGY LEVELS AND MOLECULAR CONSTANTS OF $^{12}C_2H_2$, $^{12}C_2D_2$, $^{12}C_2HD$ DETERMINED FROM INFRARED SPECTRA. Hurlock, S. C.; Ghersetti, Sergio; Rao, K. Narahari (Ohio State Univ., Columbus. Univ., Bologna). Mem. Soc. Roy. Sci. Liege; 1: No. 2, 87-97(1971).

An attempt was made to bring together the best available values for the energy levels and molecular constants of the ground electronic states of the acetylene molecule and some of its isotopic species. What were believed to be internally consistent data obtained from high resolution infrared spectra are included. (auth)

57434 DIFFUSION COEFFICIENTS OF ISOTOPIC METHANE MIXTURES AND OF METHANE–RARE GAS MIXTURES. Vugts, H. F.; Boerboom, A. J. H.; Los, J. (FOM.-Instituut voor Atoom- en Molecuulfysica, Amsterdam). Mem. Soc. Roy. Sci. Liege; 1: No. 2, 179-85(1971).

Relative diffusion coefficients were measured for three systems: CD_4-CD_3H, CD_3H-Ne, and CD_3H-Ar in the temperature range 230 to 425°K with an accuracy of 0.1%. Absolute diffusion coefficients for these mixtures could be obtained by normalizing on the self diffusion data of argon. Concerning the isotopic methane mixture theoretical calculations bearing on $(\epsilon/k)_{diff.}$ and Z_{rot} were found to be in close agreement with our experimental data. For rare gas−molecular gas mixtures explicit values for 6C-5 are given, which in the case of $Ne-CD_3H$ can be correlated with Z_{rot} based on a loaded sphere model. For $T^* < 3$ the loaded sphere model shows to be less applicable as is evident from the results of $Ar-CD_3A$. (auth)

57435 (COO–1029-39) HIGH TEMPERATURE CHEMISTRY: FUNDAMENTALS OF EFFUSION AND THERMODYNAMICS OF MATERIALS. Final Report, June 1, 1961–August 31, 1971. Wahlbeck, Phillip G. (Illinois Inst. of Tech., Chicago. Dept. of Chemistry). Contract AT(11-1)-1029. 130p. Dep. NTIS.

A publication list of research completed under this contract is presented, and tentative results are given for research now in progress on the dissociation energy of ScSe, YSe, LaSe, and TiO. (D.H.M.)

57436 STRUCTURE AND CONFORMATION OF THORIUM(IV) COMPLEXES OF DIETHYLENETRIAMINEPENTAACETIC ACID IN AQUEOUS SOLUTION. Fried, A. R. Jr.; Martell, A. E. (Texas A and M Univ., College Station). Contract AT(40-1)-3621. J. Amer. Chem. Soc.; 93: No. 19, 4695-4700(22 Sep 1971).

The aqueous (D_2O) infrared and proton NMR spectra of the 1 : 1 complexes of thorium(IV −diethylenetriaminepentaacetic acid (DTPS) were studied as a function of "a" value a = moles of base added/mole of metal ion). On the basis of ir and NMR data, plausible solution structures are proposed and compared with proposed structures from previous potentiometric studies. Unlike the 10^{-3} M potentiometric study of Th(IV) −DTPA at a = 0, the 0.10 M ir and NMR spectra at a = 0 confirm the presence of a 1 : 1 complex in which the ligand is pentadenate. A structure is proposed for the 1 : 1 DTPA complex at a = 5 (pD 5.3) on the basis of the NMR spectra. Infrared and NMR data for the complex at a = 6 (pD 10.24 indicate that the monohydroxo chelate is nine-coordinate. (auth)

57437 ELECTRON-TRANSFER AND f → d ABSORPTION BANDS OF SOME LANTHANIDE AND ACTINIDE COMPLEXES AND THE STANDARD (III–IV) OXIDATION POTENTIALS FOR EACH MEMBER OF THE LANTHANIDE AND ACTINIDE SERIES. Nugent, L. J.; Baybarz, R. D.; Burnett, J. L. (Oak Ridge National Lab., Tenn.). J. Inorg. Nucl. Chem.; 33: No. 8, 2503-30(Aug 1971).

Best values for the standard (III− IV) oxidation potentials for each member of the lanthanide series and for each member of the actinide series are obtained from a variety of sources, namely, from the direct electrode measurements reported in the literature, from linear plots of electron-transfer absorption band energy for various Ln(IV) and An(IV) complexes versus the respective (III−IV) potentials, from linear plots of f → d absorption band energy for various Ln(III) and An(III) complexes vs the respective (III−IV) potentials, and from theoretical correlations using Jørgensen's refined-electron-spin-pairing-energy theory. Two major results of this work are that the M(III−IV) potentials for M ≐ Cm, Cf, Pr, and Tb are all within −3.2 ± 0.3 V, and the indication that the unknown oxidation states Cf(IV), Es(IV), Pm(IV), Sm(IV), Fm(IV), and possibly Md(IV), listed in the order of decreasing stability, may be stabilized in various media. Altogether, the results are in excellent accord with the actinide hypothesis. (auth)

57438 THEORY OF THE ACTINIDES. Chaikhorskii, A. A. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 1-6(Jan-Feb 1971).
Translated from Radiokhimiya; 13: No. 1, 3-9(Jan-Feb 1971).

Rules of analog lines in the Mendeleev periodic law are considered. The necessary requirements for the new principle of incompatability, based on a system of five quantum numbers, are outlined. On the basis of the rule of analog lines, the principle of incompatability, and other physicochemical properties of the 4f- and 5f-elements, the "thoride" hypothesis is proposed. (auth)

57439 ELECTROMIGRATION OF IONS OF ^{22}Na, ^{42}K, ^{86}Rb, AND ^{134}Cs IN MOLTEN CHLORIDES. Shvedov, V. P.; Osipov, V. N. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 92-6(Jan-Feb 1971).
Translated from Radiokhimiya; 13: No. 1, 98-101(Jan-Feb 1971).

The mobilities of ions of ^{22}Na, ^{42}K, ^{86}Rb, and ^{134}Cs in molten chlorides of these elements were determined at various temperatures, considering the influence of evaporation on the electromigration of the ions. In the temperature interval investigated, the mobilities of the impurity ions are equal to the mobility of the cation of the background melt itself within the limits of experimental error. At temperatures close to the melting points of the chlorides, the rate of migration decreases with increasing radius of the cation of the background electrolyte. With increasing temperature, the nature of this dependence changes. The inverse proportionality between the ion mobility and the crystal chemical radius of the ion is not always fulfilled. The activation energy of the mobilities of sodium, potassium, and rubidium ions is equal to the activation energy of the mobility of cesium in cesium chloride. The experimental results obtained can be explained by association in the melts investigated. The transport numbers of the cations and anions were determined in sodium, potassium, rubidium, and cesium chlorides. The values obtained for the transport numbers are in good agreement with the data found by the Gittorf method. The material of the porous medium in which the ions move evidently has no appreciable influence on the electromigration of the ions. (auth)

57440 APPLICATION OF LAYERS OF Th, U, Np, AND Pu ON INSTRUMENT PARTS BY THE METHOD OF ELECTROLYTIC DEPOSITION. Reformatskaya, I. A. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 84-7(Jan-Feb 1971).
Translated from Radiokhimiya; 13: No. 1, 89-94(Jan-Feb 1971).

A method for electrolytic application of layers of oxides of U, Th, Np, and Pu on parts of industrial instruments from solutions of their nitrates in organic alcohols was developed. Uniform and rather strong layers with a surface density of the coating of 0.2 to 5 mg/cm^2 for U and Th and 0.2 to 1.5 mg/cm^2 for Np and Pu were obtained by the method of multilayer electrodeposition on stainless steel substrates. The method permits quantitative (up to 98.5%) solution of an element from a solution of an electrolyte in 20 to 45 min at a current density of 2 to 7 mA. The method gives well reproducible results. (auth)

57441 CHEMICALLY STABLE ELECTRODE MATERIAL IN LIQUID IRON. Kawakami, M.; Goto, K. (Tokyo Inst. of Tech.). Met. Trans.; 2: No. 10, 2965-6(Oct 1971).

V_2O_3 was tested as a possible electrode material in liquid Fe for electric or electrochemical measurements. After immersion in liquid Fe for an hour, a thin FeV_2O_4 layer was formed on the V_2O_3 rods, but the V content in the Fe was virtually zero.

V_2O_3 was found to be stable in H_2 and Ar streams at 1550°C. The electric conductivity of V_2O_3 was found to be high ($\log \sigma = 3.17 - 1.0 \times 10^3$ T) with no rectifying action. The emf of the cell Mo, MoO_2/ZrO_2, CaO/liquid Fe, V_2O_3 was found to be stable for 1 hr at 1550°C. (D.L.C.)

Radiation and Nuclear Chemistry

57442 SOME PROBLEMS OF NUCLEAR CHEMISTRY. Gol'danskii, V. I. Vestn. Akad. Nauk SSSR; No. 9, 73-84(Sep 1969). (In Russian).

The work of the Institute of Chemical Physics and similar institutes of the Academy of Sciences in the USSR is summarized. "Hot atom" chemistry is exemplified by an investigation of neutron-irradiated systems containing a sulfur-containing organic compound and either HCl or CCl_4. Introduction of a 16.5-keV ^{35}S atom into the system from the reaction $^{35}Cl(n,p)^{35}S$ offers a large probability of replacing the nonradioactive S by ^{35}S. Replacements of 7 to 60% are reported. The fixation of nitrogen in the form of NO_2, NH_3, or HCN in various gaseous systems (e.g., $N_2 + CH_4$) by means of heavy ions did not produce greater yields than found for protons, electrons, and gamma radiation. Symmetrical and asymmetrical doublets of quadripolar splitting of Moessbauer spectral lines were obtained. The Zeeman splitting of spectral lines of ^{119}Sn was observed in (Y,Ca, Sn,Fe,O) complexes, and it was established that Sn was connected to Fe through an oxygen bridge. Spectra of 4-coordinate yellow complexes of Fe with compounds such as methylnaphthyldithiol and α-nitroso-β-naphthol furnished evidence as to the choice between planar vs distorted structural forms of the Fe-coordination bonding. A detailed list of similar phenomena under study is set forth. (K.S.W.)

57443 ELECTRON IRRADIATION OF DILUTE AQUEOUS SOLUTIONS OF POLYMERS OVER A RANGE OF TEMPERATURES. Davies, J. M.; Zagieboylo, W. (Army Natick Labs., Mass.). Int. J. Appl. Radiat. Isotop.; 22: No. 9, 521-8(Sep 1971).

Dilute aqueous solutions of carboxy methyl cellulose (CMC) and gelatin were irradiated with 1-MeV electrons over the temperature range from +25°C to very low temperatures, −70 to 170°C. The effects, chain scission in CMC and crosslinking in gelatin, were measured by determining the viscosity change of CMC solutions and the insoluble gel fraction produced in gelatin solutions. For both solutions there was a great change in the effect near the freezing temperature, but there were some differences in behavior between the two materials. With CMC there was a sharp break near 0°C with the rate of change 37 times as great above 0°C as below 0°C; there was apparently no change from ~0°C down to −170°C. With gelatin the change was somewhat more gradual near freezing. The rate was 7.5 times as great at +5°C as at −5°C, with a continual change over that temperature range and a continuing change in rate down to −70°C. The crosslinking rate depends on the mobility of the polymer chains and apparently for the gelatin solutions the mobility continues to decrease as the temperature is lowered below freezing. (auth)

Radiation Effects

57444 INFLUENCE OF IONIZING RADIATION ON THE CATALYTIC ACTIVITY OF IRON CATALYSTS FOR AMMONIA SYNTHESIS. Stepan, O.; Stverak, B. (Inst. for Research, Production, and Use of Radioisotopes, Prague). Collect. Czech. Chem. Commun.; 36: No. 6, 2358-61(Jun 1971).

The effects of the following factors on the catalytic activity of iron in the synthesis of ammonia were investigated: activation in a reactor, incorporation of ^{90}Y, and irradiation with ^{60}Co γ radiation. Irradiation in the reactor resulted in a decrease in rate constants and an increase of activation energies. A higher catalytic activity was found in radioactive catalysts. No effects were observed from γ irradiation. (M.C.G.)

57445 UNSTABLE INTERMEDIATES. PART XCVIII. ELECTRON SPIN RESONANCE SPECTRA FOR VARIOUS ANTIMONATE RADICALS IN γ-IRRADIATED POTASSIUM ANTIMONATE AND SODIUM HEXAFLUOROANTIMONATE. Symons, M. C. R. (Univ. of Leicester, Eng.). J. Chem. Soc., A; No. 14, 2393-6(1971).

Exposure of potassium antimonate to ^{60}Co γ-rays gave a radical whose ESR spectrum was close to that expected for SbO_4^{2-} radicals. Similar treatment for sodium hexafluoroantimonate gave a radical with a comparable ESR spectrum, suggesting that the species is of the form $\dot{O}-SbX_\alpha$ rather than SbF_5- or SbF_6^{2-}, as previously suggested. (auth)

57446 THERMOSTABILIZATION OF IRRADIATED FILLED POLYETHYLENE. Yanson, I. R.; Karlivan, V. P.; Kal'kis, V. Ya.; Rayave, E. L. (Inst. of Physics, Riga). Modif. Polim. Mater.: No. 2, 100-6(1969). (In Russian).

An investigation was conducted on thermostability of irradiated filled polyethylene, where the filler was identified as one of the following: kaolin, chalk, talc, Fe_2O_3, SiO_2, TiO_2, and Al. Toughness and percent elongation of samples were measured and compared with those of unfilled polyethylene as a means of evaluation. The nature of the filler significantly affected the shape of the stability–time curves. The effectiveness of thermostabilization depended both on the filler used (15% by weight) and the antioxidant incorporated (2%) in the polyethylene. The best antioxidants among those tested were 2,2'-thiobis(6-tributyl-p-cresol) (CaO-6), and di-β-naphthyl-n-phenylenediamine. Light stability was greatly enhanced by the combined use of antioxidant CaO-6 and the light absorber Tinuvin 326. (K.S.W.)

57447 STRUCTURE OF IRRADIATED TELLURITE GLASSES. Galimov, D. G.; Sherstyuk, A. I.; Yudin, D. M.; Yakhkind, A. K. Zh. Strukt. Khim.; 12: No. 3, 408-14(May-Jun 1971). (In Russian).

The electron paramagnetic resonance spectra of γ-irradiated tellurite glasses were investigated. A sodium–tellurium glass containing 18 mole % Na_2O constituted the basic matrix, and to this was added small amounts of a series of oxides, e.g., La_2O_3, Eu_2O_3, Yb_2O_3, and MnO_2. Samples of these glasses were irradiated with ^{60}Co-radiation at 40°C. The EPR spectra were taken at the temperature of liquid nitrogen: two types were found with $g_1 = 2.00$ and $g_2 = 1.97$, which were associated with octahedral and tetrahedral structural forms in the tellurite glasses. The problems of these structures are discussed. (K.S.W.)

57448 EFFECTS OF NUCLEAR RADIATION ON THE ACTIVITY OF A PALLADIUM CATALYST FOR THE HYDROGENATION OF BUTYNEDIOL. Sokol'skii, D. V.; Nadykto, B. T.; Pak, A. M.; Korolev, A. V. At. Energ. (USSR); 31: No. 3, 283-5(Sep 1971).

The changes in catalytic activity of palladium black caused by various exposures to neutron fluxes were studied. The integrated thermal neutron fluxes used were generated in a nuclear reactor and were 1.6×10^{16} and 1.6×10^{19} n/cm^2, respectively; the former exposure resulted in distinctly improved catalytic properties by a factor of 2.6 by reducing the particle size and increasing the specific surface from 68.2 to 100.0 m^2/g. The yield of butenediol was increased from 73 to 89%. (K.S.W.)

57449 ESR STUDY OF VANADYL ION IN AN IRRADIATED VANADO COMPLEX. Srinivasan, R.; Subramanian, C. K. (Indian Inst. of Science, Bangalore). Indian J. Pure Appl. Phys.; 9: No. 1, 24-6(Jan 1971).

An ESR study of x- or uv-irradiated diamagnetic $(NH_4)_3[VO_2(C_2O_4)_2]2H_2O$ revealed the formation of oriented stable vanadyl ions in the host lattice. The centers were found to be stable when trapped in the crystalline state but were chemically unstable. ESR absorption of the irradiated sample, even after storage for one year, indicated the stability of these centers. The unpaired electrons of the center studied appear to exist in the d_{xy} orbital of the vanadium ion. Previously reported molecular orbital calculations and optical absorption results were used along with the ESR data to reveal a covalent in-plane σ bond and an out-of-plane ionic π bond. (auth)

Radiation Processes

57450 (ORO–3667-1) RESEARCH AND DEVELOPMENT STUDIES INTO THE BASIC TECHNOLOGY OF RADIATION INDUCED IONIC POLYMERIZATION INCLUDING SMALL SCALE PILOT PLANT SYSTEMS. Final Report. Stannett, V.; Stahel, E. P.; Kohler, J.; Oda, E.; Omi, S.; Goineau, A.; Shah, H. P.; Osborne, F. T. (North Carolina State Univ., Raleigh. Dept. of Chemical Engineering). 1 Jun 1971. Contract AT(40-1)-3667. 120p. Dep. NTIS.

Studies were conducted in depth of the radiation-induced polymerization of vinyl monomers under superdry conditions. Basic laboratory studies and engineering pilot plant research were carried out. Results show that neither vinyl chloride nor molten or solutions of trioxane could be induced to polymerize ionically even after the most stringent drying; β pinene was found to polymerize readily after drying; in a study of a series of alpha olefins analogous to isobutylene only isobutylene polymerized ionically; isobutyl vinyl ether was polymerized at the highest yields yet reported; and isopropyl vinyl ether was polymerized under optimum conditions for the first time with a square root dependence of the rate on the dose rate. A recirculating flow reactor system was used to study the radiation-induced polymerization of styrene and α-methylstyrene in bulk and solution. (D.H.M.)

57451 HIGHLY RADIATION-SENSITIVE AMIDES. D'Alelio, Gattano Francis (to PPG Industries, Inc.). British Patent 1,241,622. 4 Aug 1971. Filed 20 Mar 1969.

XUM

Reference is made to amides that are converted to three-dimensional crosslinked, insoluble, and infusible polymers at relatively low radiation doses, such as diacrylyl compounds containing amide groups, and a process is described for producing an improved polyamide resin composition involving treatment of a diacrylylamide with 0.5 to 10 MR of high-energy ionizing radiation of at least 10^5 eV. The diacrylylpolyamide may be admixed with a polyamide resin having a molecular weight of at least 500, or a copolymerisable monomer, or an unsaturated aliphatic alkyd resin. A number of examples are described. (UK)

57452 SYNERGISTIC TREATMENT OF TEXTILE DYE WASTES BY IRRADIATION AND OXIDATION. Craft, T. F.; Eichholz, G. G. (Georgia Inst. of Tech., Atlanta). Int. J. Appl. Radiat. Isotop.; 22: No. 9, 543-7(Sep 1971).

Tests on representative textile dye solutions were performed to compare decoloration effects by treatment with an oxidant, γ radiation, or both. In most cases the combined treatment was much more effective than either alone. The radiation effect was found to be very rapid, with adequate dose rates of the order of 35 to 80 krad and 50 to 100 ppM NaOCl. (auth)

57453 KINETICS OF RADIATION INDUCED SOLID STATE POLYMERIZATION OF TRIOXANE. Rao, M. H.; Rao, K. N. (Bhabha Atomic Research Centre, Trombay, India). Radiat. Eff.; 10: No. 1-2, 87-91(Jul 1971).

The radioinduced polymerization of highly purified trioxane in the solid state was carried out at 56, 51, 46, 31, and 25°C. The polymerization went to completion at all the temperatures studied and the rate of polymerization remained unaltered between 46 to 56°C and 25 to 31°C, but however the rate of polymerization at lower temperature range was half of what was observed at higher temperature range. The rate of polymerization was proportional to the monomer concentration. The polymerization went to completion even with microcrystalline solid and the dose rate exponent was observed to be 0.53. All these results indicate that the defects are not playing any role in the termination reaction. (auth)

57454 EFFECT OF ADDITIVES ON THE RADIOCHEMICAL POLYMERIZATION OF STYRENE IN SOLUTIONS OF CCl_4 OR HEXACHLOROBUTADIENE. Gorzny, K. (Kernforschungsanlage, Juelich, Ger.). Makromol. Chem.; 138: No. 3448, 251-64 (1970). (In German).

The radioinduced polymerization of styrene in solutions of CCl_4 or hexachlorobutadiene at room temperature can be described by a radical mechanism. From the dependence of the relative rate of polymerization on the mole fraction of styrene an energy transfer from styrene to the halogen component is assumed. This transfer, which is caused by a transfer of excitation, is quenched by addition of anthracene, 1,3-pentadiene, and less effectively by p-terphenyl, but is not quenched by addition of naphthalene or anisole. The initiation of polymerization is achieved preferably by radicals formed by the halogen components. Besides this energy transfer a dissociative electron capture producing radicals, which can start the polymerization, occurs. (auth)

57455 KRYPTON DIFLUORIDE. Prusakov, V. N.; Sokolov, V. B. At. Energ. (USSR); 31: No. 3, 259-68(Sep 1971). (In Russian).

Data on krypton difluoride published up to the beginning of 1971 are reviewed. This simple compound of krypton is prepared by passing electrical discharge through a mixture of the elements at a low temperature (–183 to 196°C) and a low pressure (20 to 40 mm) or by irradiation of a mixture of krypton and fluorine with 1.5-MeV electrons and 10-MeV protons. The physical and chemical properties of krypton difluoride are reviewed. KrF_2 differs markedly from xenon fluorides by its higher chemical reactivity. Krypton difluoride would be anticipated to be a fluorine ion donor, but it yields to the xenon difluoride and xenon hexafluoride in this respect. The experimental and theoretical studies of the bonding in krypton difluoride are reviewed. (auth)

57456 INVESTIGATION OF THE POLYMERS FORMED IN REACTOR IRRADIATED BENZENE OR TOLUENE TOGETHER WITH AlN. Barakat, M. F.; Abdel-Kerim, Fawzi M. (Atomic Energy Establishment, Cairo). J. Inorg. Nucl. Chem.; 33: No. 8, 2301-9(Aug 1971).

Studies of recoil carbon atoms in organic media revealed the preferential location of activity in the polymeric products. The polymers formed in neutron-irradiated benzene or toluene, mixed with AlN for carbon recoil generation, were separated and analyzed. Gas chromatographic analysis showed that polymerization of irradiated benzene, either in the presence or absence of AlN, occurred to the same extent indicating that the process is mainly a radiation effect. In toluene the recoil events were found to have a remarkable effect on the polymerization. The ir spectra of the polymers were compared with those of the pure parent compounds. The spectra showed that the polymers have polystyrene-like structures. Marked similarity with the known polystyrene ir spectrum was observed. The preferential location of the activity in the polymers was attributed to the formation of easily polymerizable entities through both the primary attack of carbon recoils on C—H or C—C bonds of the matrix molecules and also hydrogen abstraction by energetic recoils to form reactive $^{14}CH_2$·· radicals. Possible mechanisms of formation of the different polymers were suggested. (auth)

Radiolysis

57457 (ARH–2163) RADIOLYSIS OF CITRIC ACID SOLUTION. Edvalson, Lars E. (Atlantic Richfield Hanford Co., Richland, Wash.). 1 Aug 1971. Contract AT(45-1)-2130. 13p. Dep. NTIS.

Radiolysis of citric acid in solutions of HNO_3–$Sr(NO_3)_2$ by a cobalt-60 gamma source has a G value of 0.80. For each mole of citric acid destroyed, an average of 7.00 moles of hydrogen ion disappear. Concentrations of citric acid and nitric acid at which dark brown radiolysis products and/or solids formed were also determined. (auth)

57458 (COO–1116-17) [KINETICS OF IONIZING-RADIATION INDUCED REACTIONS IN ORGANIC COMPOUNDS]. Progress Report, December 1, 1970–November 30, 1971. Firestone, F. R. (Ohio State Univ., Columbus. Dept. of Chemistry). Contract AT(11-1)-1116. 69p. Dep. NTIS.

Results of a study of the absorption spectra and kinetics of decay of transient species formed upon the pulsed irradiation of n-pentane, aqueous solutions of n-pentane, and oxygenated n-pentane are reported. The kinetics of decay are interpreted in terms of a model describing the effects of diffusion upon reactions in solution. (D.H.M.)

57459 (DP–1264) RADIOLYSIS OF LIQUID WASTE DURING BEDROCK STORAGE. Bradley, R. F. (Du Pont de Nemours (E. I.) and Co., Aiken, S. C. Savannah River Lab.). Aug 1971. Contract AT(07-2)-1. 24p. Dep. NTIS.

A proposed method for long-term containment of radioactive wastes produced at the Savannah River Plant is storage in vaults excavated in crystalline rock 1500 ft beneath the surface of the plant. Radiolysis of the waste to form gases will occur during storage of the waste. Tests with synthetic wastes to develop design data on the radiolytic gas evolution rates are summarized. These tests showed that a vapor volume of ~15% of the total sealed volume would be sufficient to keep the pressure in the storage vault below the surrounding 1500-ft hydrostatic pressure. These tests also provide part of the basic data necessary to predict the behavior of the gases and the liquid waste over the ~1000 years of storage necessary for the decay of ^{90}Sr and ^{137}Cs to innocuous levels. (auth)

57460 CHARGE EXCHANGE AND TRANSITION REACTIONS OF A HYDROGEN ATOM DURING COLLISIONS OF ARGON IONS WITH WATER MOLECULES. Arifov, U. A.; Pozharov, S. L.; Chernov, I. G. (Inst. of Nuclear Physics, Tashkent). Izv. Akad. Nauk Uzb. SSR, Ser. Fiz.-Mat. Nauk; No. 2, 49-52(1971). (In Russian).

The results of a mass spectrometric study of an ion-molecule reaction to form H_3O^+ are given. A mixture of Ar and H_2O vapor (10 to 40 torr) were irradiated with β particles from a Zr–T source of about 30 μCi. An eleven-step series of reactions is proposed to illustrate the mechanism, ending with H_3O^+. The effect of the pressure on this mechanism was investigated. (K.S.W.).

57461 γ-RADIOLYSIS OF GASEOUS CARBON DIOXIDE AT HIGH DENSITIES. Yoshimura, M.; Chosa, M.; Soma, Y.; Nishikawa, M. (Tokyo Univ.). J. Chem. Soc., D; No. 16, 980-1(25 Aug 1971).

G(CO) from γ-irradiated gaseous carbon dioxide at 50 ± 1°C showed a marked increase with density increase above 0.2 g/ml, owing to the increased probability of geminate recombination of ion pairs at high densities. (auth)

57462 EFFICIENCY OF SOME ANTIOXIDANTS IN THE THERMOOXIDATIVE DEGRADATION OF IRRADIATED POLYETHYLENE. Yanson, I. R.; Karlivan, V. P.; Kal'kis, V. Ya.; Rayave, E. L. (Inst. of Physics, Riga). Modif. Polim. Mater.; No. 2, 107-10(1969). (In Russian).

The thermostabilizing effect of several antioxidants on low-density polyethylene was investigated by incorporating the agents into polyethylene on heated rollers and then exposing them to gamma radiation. The antioxidants tested were: 2,2′-thio-bis-(6-tributyl-p-cresol)(CaO-6), tri-(2-methyl-4-oxy-5-tributylphenyl)-butane (Topanol CA), o-oxyphenylazodimedone, and dilaurylthiodipropionate. As a reference standard the compounds di-β-naphthyl-p-phenylenediamine was made a part of the testing program. Concentrations of these additives in the polyethylene were 0.5, 1.2, and 5%. A beneficial effect in stabilizing irradiated polyethylene against heat was observed for the phenolic antioxidants CaO-6 and Topanol CA, the optimal concentration being about 2%. A significant radiation-protective effect was noted for CaO-6. (K.S.W.)

57463 LIGHT EMISSION FROM GAMMA-IRRADIATED ALKANE GLASSES CONTAINING OLEFINS. Brocklehurst, B.; Robinson, J. S. (Univ. of Sheffield, Eng.). Chem. Phys. Lett.; 10: No. 3, 277-9(1 Aug 1971).

After gamma radiolysis at 77°K, glassy alkanes emit weakly in the visible on warming. The similar but stronger emission from dilute olefin solutions suggests that the alkane luminescence is due to radiolysis products. The nature of the emitters is discussed: it is concluded tentatively that they are olefins in twisted excited states formed by recombination of olefin cations. (auth)

57464 ROLE OF THE EXTERNAL SURFACE OF CRYSTALLINE ALKALI HALIDES IN RADIATION INDUCED CHEMICAL DECOMPOSITION. Sugier, H. (Technical Univ., Lodz, Poland). Radiochem. Radioanal. Lett.; 7: No. 5-6, 303-4(10 Sep 1971).

57465 RADICALS IN γ-IRRADIATED HYDRATES OF CYCLIC ETHERS. Trofimov, V. I.; Chkheidze, I. I. (Inst. of Chemical Physics, Moscow). Dokl. Akad, Nauk SSSR; 198: No. 2, 354-7 (11 May 1971). (In Russian).

Cyclic ethers are known to form clathrate compounds with water. The hydrates of the two cyclic ethers, tetrahydrofuran C_4H_8O (THF) and 1,3-dioxolane, $C_3H_6O_2$ (DO), were irradiated with ^{60}Co gamma radiation at 77°K, and the electron paramagnetic resonance (EPR) spectra at different temperatures were determined. These EPR spectra are compared with those of pure ice and pure THF and DO, and the structures of possible free radicals and the locations of an unpaired electron are examined. (K.S.W.)

57466 TRANSIENT SPECIES IN THE PULSE RADIOLYSIS OF PERIODATE ION IN NEUTRAL AQUEOUS SOLUTIONS. Barat, F.; Gilles, L.; Hickel, B.; Lesigne, B. (CEN de Saclay, Gif-sur-Yevette, France). J. Chem. Soc., D: No. 15, 847-8 (11 Aug 1971).

IO_4^{2-} (ϵ_{360} ca. 1000 M^{-1} cm^{-1}) ions and $IO_4^{\cdot}$ ϵ_{520} ca. 3000 M^{-1} cm^{-1}) radicals are formed by pulse radiolysis of periodate ion in aqueous solution. (auth)

57467 INITIAL FATE OF HYDROGEN ATOMS AND HYDROXYL RADICALS IN THE RADIOLYSIS OF FROZEN AQUEOUS SOLUTIONS OF ALKALI HALIDES. Ginns, I. S.; Symons, M. C. R. (Univ. of Leicester, Eng.). J. Chem. Soc., D; No. 16, 949-50 (25 Aug 1971).

After exposure to ^{60}Co γ-rays, aqueous glasses containing sodium or potassium fluoride, chloride, bromide, or iodide gave ESR spectra containing features characteristic of the radicals $H\cdot$, MH^+, $\cdot OH$, and $halOH^-$. (auth)

57468 OPTICAL MEASUREMENTS ON SOLVATED ELECTRONS IN PULSE-IRRADIATED LIQUID PROPANE. Gillis, H. A.; Klassen, N. V.; Teather, G. G.; Lokan, K. H. (National Research Council of Canada, Ottawa). Chem. Phys. Lett.; 10: No. 4, 481-3(15 Aug 1971).

A broad absorption spectrum with $\lambda_{max} \geq 2000$ nm has been observed in pulse-irradiated liquid propane at low temperatures and assigned to the solvated electron. The electron decays by geminate recombination with an initial half-life of ≤95 nsec at −185°C. (auth)

57469 RADIOLYSIS OF BENZENE VAPOUR BY LOW-ENERGY HEAVY IONS. Olsen, K. J. (Aarhus Univ., Denmark). Trans. Faraday Soc.; 67: No. 583, 2050-6(Jul 1971).

Radiolysis of benzene vapor was studied using 60-keV Ne^+, Ar^+, Kr^+, Xe^+, and Pb^+ ion beams from an electromagnetic isotope separator. Radiolytic products were investigated both directly by emission spectroscopy and indirectly with ESR spectroscopy and chemical analysis of the deposits formed by condensing the irradiated vapor. H atoms were detected in the gas phase, C_6H_5 and C_6H_7 in the condensate. No products were detected after dissolution of the condensates. Results from irradiation of C_6H_5D vapor indicate that all H atoms in the phenyl radical are equivalent with a hyperfine coupling constant of 4.1 G. The ratio between C_6H_5 and C_6H_7 increases with increasing mass of the radiolyzing ion. Relative and absolute cross-sections for production of radicals with the ions mentioned above are compared with theoretical calculations for the reaction $C_6H_6 + \text{ion} \rightarrow C_6H_5 + H + \text{ion}$. (auth)

57470 ELECTRON PARAMAGNETIC RESONANCE OF ELECTRON-IRRADIATED AMMONIA LAYERS. Beuermann, G. Univ., Goettingen, Ger.). Z; Phys.; 247: No. 1, 25-31(1971). (In German).

Ammonia, NH_3 or ND_3, is vaporized upon a cold substrate (20 to 100°K) and irradiated with electrons of energies from 0.2 to 6 keV. The different EPR spectra show hyperfine structure and may be ascribed to centers of the type H_2^-, D_2^-, $(NH_2^-)^-$, $(ND_2^-)^-$. With respect to electrostatic charge a chemical decomposition of ammonia must be assumed. No electronic centers are found that could be compared with the solvated electrons known in liquid metal–ammonia solutions or quenched solid metal–ammonia layers. (auth)

57471 ESR STUDY OF GAMMA-IRRADIATED SINGLE CRYSTALS OF POTASSIUM BICARBONATE AT 77°K. Holmberg, Robert W. (Oak Ridge National Lab., Tenn.). J. Chem. Phys.; 55: No. 4, 1730-5(15 Aug 1971).

Several paramagnetic centers are formed when single crystals of $KHCO_3$ or $KDCO_3$ are gamma-irradiated at 77°K. Their magnetic properties were studied using electron spin resonance. The two centers formed predominantly were identified as the free radicals $(HCO_3)_2^-$. and $\dot{C}O_3^{2-}$. Lesser amounts of HCO_3. were found trapped in two different sites in the crystal. When the crystals are warmed to room temperature (or when irradiated at room temperature), another radical with properties like CO_2^- is formed. (auth)

57472 EFFECT OF THALLOUS IONS ON THE YIELDS OF HYDROGEN AND HYDROGEN PEROXIDE IN RADIOLYZED AQUEOUS SOLUTIONS. Faraggi, M. (Nuclear Research Center, Negev, Israel); Zehavi, D.; Anbar, M. Trans. Faraday Soc.; 67: No. 583, 2057-67(Jul 1971).

The radiolysis of Tl_2SO_4 in neutral and in 0.8 N H_2SO_4 aqueous solutions in the presence and absence of air was investigated. In the absence of air and with low doses of radiation, a steady-state concentration of H_2O_2 is observed. In air-saturated solutions $G(H_2O_2)$ decreases with Tl^+ concentration. The effect of Tl^+ on $G_{H_2O_2}$ was measured by two independent methods, following $G(H_2O_2)$ in aerated solutions and by measuring $G(H_2O_2^{18,18})$ formed in H_2O^{18} in the presence of $H_2O_2^{16,16}$ as protective additive. In neutral and acid solutions, $G(H_2) = G_{H_2} = 0.42 \pm 0.02$, which was independent of Tl^+ concentration. The relatively high efficiency of Tl^+ for scavenging the precursor of H_2O_2 is discussed and compared with that of other reactants known to diminish $G_{H_2O_2}$. The mode of formation of the "molecular" products in the radiolysis of water is discussed in the light of the findings. (auth)

57473 MECHANISM OF THE RADIOLYSIS OF CYCLOHEXANE. Herler, Horst (Technische Univ., Munich). Angew. Chem. Int. Ed. Engl.; 10: No. 6, 420-1(Jun 1971).

The three main products of the radiolysis of cyclohexane (hydrogen, cyclohexene, and bicyclohexene) are formed by rupture of C—H bonds. Absorption of ionizing radiation leads to excited and ionized cyclohexane molecules and to electrons. Amounts of the main products of radiolysis of cyclohexane are increased by addition of small quantities of organic compounds such as benzene, anthracene, and pyrene; the amounts of all three products are maximal at ca. 10^{-4} mole of aromatic compound per liter. Studies using electron scavengers indicate that the probability of ion–electron recombination is about 0.7 if that for ion–molecule reactions is set at 1. (J.G.B.)

57474 GAMMA RADIOLYSIS OF GASEOUS ETHYLENE IN THE PRESENCE OF ISOBUTYLENE. Niedzielski, J.; Gawlowski, J. (Univ. of Warsaw). Radiat. Eff.; 10: No. 1-2, 1-7(Jul 1971).

The effective consumption of isobutylene added to gamma-irradiated ethylene was attributed to ion-molecule reactions. Approximately 4 molecules of isobutylene were used per ion pair (for 0.2 % vol of isobutylene in ethylene). The neutralization of ions, having isobutylene molecules inserted, did not yield hydrogen atoms, as evidenced by the depression in the yields of normal paraffins. In the absence of isobutylene the yield of H atoms from the neutralization of ions was approximately 0.6 G_{ion}. The formation of isobutane, due to the presence of isobutylene, was attributed mainly to two distinct ion-molecule reactions. (auth)

57475 RATE CONSTANTS OF REACTIONS OF PHOTOGENERATED SOLVATED ELECTRONS WITH MONOMERS. Moorthy, P. N.; Kumar, Vijay; Rao, K. N.; Shankar, J. (Bhabha Atomic Research Centre, Trombay, India). Radiat. Eff.; 10: No. 1-2, 129-31(Jul 1971).

The reaction rate constants of solvated electrons were measured in a flash photolysis apparatus for the following monomers: acrylonitrile, methyl acrylate, ethyl acrylate, methyl methacrylate, vinyl isobutyl ether, N-vinylpyrrolidone, vinyl acetate, vinyl benzoate, methacrylic acid, acrylamide, s-trioxane, ethylene, and styrene. The nonvinylic monomers are rather unreactive, but conjugation of the ethylenic double bond with the benzene ring, carbonyl, or cyano group results in high reactivity. (D.L.C.)

57476 RADICALS OF THE γ-IRRADIATED HYDRATES OF THE THREE-MEMBERED CYCLES. Trofimov, V. I.; Blumenfeld, A. L.; Kostyanovskii, R. G.; Chkheidze, I. I. (Inst. of Chemical Physics, Moscow). Tetrahedron Lett.; No. 35, 3267-70(Aug 1971).

The striking increase in stability of the radicals formed by γ-irradiation of clathrate hydrates of cyclopropane, ethylene oxide, and propylene oxide is reported. (auth)

57477 RADIOLYTIC FORMATION OF LONG-LIVED AMMONIATED ELECTRONS AT ROOM TEMPERATURE. Belloni, J.; de la Renaudiere, J. F. (Faculte des Sciences, Orsay, France). Nature (London) Phys. Sci.; 232: No. 34, 173-4(23 Aug 1971).

The γ radiolysis of a 5×10^{-2}M solution of KNH_2 and hydrogen at pressures from 0.2 to 0.8 atm was studied in order to clarify the mechanism for the production of e^-_{m}. Absorbance in the visible and near infrared was recorded before and after irradiation, the slow post-irradiation decay being accelerated by contacting the solution with Pt foil. Results indicate the formation of a species with properties similar to those of solvated electrons from metal–ammonia solutions, provided that the disappearance reactions of e_{am} with NH_2 radicals and NH_4^+ ions are prevented. (J.G.B.)

57478 RADIOLYSIS OF PETROLEUM PRODUCTS. Reyes Lujan, Javier (Comision Nacional de Energia Nuclear, Mexico City. Univ. Nacional de Mexico, Mexico City). Rev. Mex. Fis.; 19: FA1-40(1970). (In Spanish).

The advances made in the area of radiolysis of petroleum products are reviewed. The radiation cracking of crude petroleum and the combination of radiation with the conventional thermal or catalytic cracking procedures are discussed. The radiation treatment of various fractions of petroleum or refined products in order to obtain products with special properties that are unobtainable with conventional procedures is considered. The radiation treatment of residual products of normal refining in order to obtain new useful products is discussed. (J.S.R.)

Radioisotope Production

57479 (BMBW-FBK-71-6) CALCULATIONS FOR PRODUCTION OF ^{231}Pa AND ^{232}U BY NEUTRON IRRADIATION FROM ^{230}Th AND ^{232}Th MIXTURES IN THE REACTOR WITH VARIOUS IRRADIATION CONDITIONS. Kim, J. I.; Gueckel, W. (Technische Hochschule, Munich (West Germany). Institut fuer Radiochemie). Jun 1971. 264p. (In German). Dep. NTIS (U. S. Sales Only).

Calculations were made for production of ^{231}Pa and ^{232}U by reactor neutron irradiation of thorium–ionium mixtures. The production yields of all transmuted nuclides in the system were calculated with respect to all irradiation conditions available from thermal reactors. The resonance flux was also included in the calculations. From results the buildup patterns of ^{231}Pa and ^{232}U are demonstrated and some examples of production schemes prepared. Discussions are made on the effective irradiation conditions, the efficacity of production, the dilution of ^{232}U in total uranium, and the irradiation of thorium with low ionium concentration. (auth)

57480 (JINR-P6-5955) FAST THERMOCHEMICAL METHODS OF SEPARATION OF RADIOACTIVE ELEMENTS. I. PRODUCTION OF THE RADIOACTIVE Re ISOTOPES. Bayar, B.; Zaitseva, N. G.; Novgorodova, A. F. (Joint Inst. for Nuclear Research, Dubna (USSR). Lab. of Nuclear Problems). 1971. 18p. (In Russian). Dep. NTIS (U. S. Sales Only).

On the basis of the thermochemical properties of Re oxides a fast gas thermochromatographic method was developed for separation of Re from the complex mixture of products produced by bombarding NH_4ReO_4 and OS_{met} targets with high-energy protons. This method allows radioactive samples of Re to be obtained for studying of nuclear-spectroscopic properties of short-lived isotopes with a half-life of several minutes. (auth)

57481 (KURRI-TR-76, pp 8-14) CHEMICAL SEPARATION IN AN ISOTOPE SEPARATION ON-LINE (ISOL) SYSTEM. Kume, Sanshiro (Kyoto Univ. (Japan). Research Reactor Inst.). (In Japanese).

From Meeting on nuclei with short life; Osaka, Japan (30 Jun 1969).

In Reports of the study meeting on nuclei with short life.

Super-fast chemistry for the study of short-lived nuclei far off beta stability line is discussed. Objective nuclides are produced by reaction through highly excited compound nuclei, and various other nuclides are produced simultaneously. The nuclide, therefore, must be separated chemically from the others, and mass separation with an isotope separator on-line (ISOL) is carried out. This chemical separation should be performed within a very short time because of short lifetime of the nuclei produced. Main processes of the separation are extraction of the nuclides from a target, transportation, chemical separation, and ionization as ion source of the mass separator. Two methods are considered for the extraction. The one is a diffusion-evaporation method. The nuclides come out from the target by the diffusion process. The target is usually maintained at high temperature. The other method is the recoil method. The nuclides come from the target with the aid of recoil energy. The extraction time is negligibly short. The flight path of the recoiling ions, however, is short; and the target should be thin. The transportation of the nuclides is performed by flowing carrier gas such as nitrogen or helium. Sometimes, some element is removed during the transportation by the use of condensation process. The super-fast chemistry is very important in the ISOL system, but still a method for selective separation is not established. Wet methods may be impossible within a very short time. Dry methods were tried. For example, the nuclei in the carrier gas are contacted with reaction material until chemical equilibrium is reached. Hot-atom chemistry is also used for the chemical separation. A table of ISOL systems currently in use throughout the world is presented. (Japan)

57482 (ORNL-tr-2535) ELAN-2B, PILOT PLANT FOR ^{137}Cs AND ^{90}Sr SOURCES. Prevotel, Marc. Translated by Martha Gerrard (Oak Ridge National Lab., Tenn.), from Ind. At.; 14: No. 9/10, 41-6(1970). 7p. Dep. NTIS.

An abstract of this paper, prepared from the original language, appeared as NSA 25: 23633.

57483 PREPARATION OF ^{99m}Tc BY DIRECT ADSORPTION FROM ORGANIC SOLUTION. Tachimori, Syoichi; Amano, Hiroshi; Nakamura, Haruto (Japan Atomic Energy Research Inst., Tokai). J. Nucl. Sci. Technol. (Tokyo); 8: No. 7, 357-62 (Jul 1971).

Purification of ^{99m}Tc extracted into methyl ethyl ketone from an alkaline solution of neutron-irradiated MoO_3 was studied in order to establish a rapid method for producing ^{99m}Tc. After removal of the organic solvent by evaporation, ^{99m}Tc could be purified from remaining traces of Mo and other contaminants by adsorption in an alumina column from an aqueous solution and by subsequent elution with 0.1N HCl or with physiological saline solution. Organic solvents containing ^{99m}Tc could also be treated directly in an alumina column to purify the ^{99m}Tc. This method saved the time required for the evaporation of the solvent. Problems essential to the adsorption of ^{99m}Tc on alumina in organic media were studied to determine the optimum conditions for the adsorption. A standard procedure for ^{99m}Tc preparation would consist of extraction of the ^{99m}Tc into methyl ethyl ketone from alkaline solution, passing the organic phase through a cation exchange column to remove Na and then through an alumina column, and finally, elution of ^{99m}Tc from alumina column with 0.1N HCl or saline solution. The process can be finished within 1 hr. About 500 mCi of ^{99m}Tc is obtained with a chemical yield higher than 95%, and the product contains less than 10^{-4}% of radiochemical impurities. (auth)

57484 GENERATOR SUBSTANCE FOR PRODUCING RADIOACTIVE ^{137m}Ba. Bernhard, Horst; Lieser, Karl-Heinrich (to EURATOM). British Patent 1,242,159. 11 Aug 1971. Priority date 12 Dec 1968, Germany.

A method for prolonging the life of a ^{137}Cs generator for the production of ^{137m}Ba is proposed. Contamination of the desired product or loss of ^{137}Cs by successive milking operations is reduced by the use of a carrier or framework substance consisting of iron or steel, the surface of which is coated with a thin layer of iron ferrocyanide to which the ^{137}Cs is fixed. The generator, which has a practically unlimited life, can be eluted rapidly and produces ^{137m}Ba with a decontamination factor of more than 10^6. (J.G.B.)

57485 METHOD OF PRODUCING GASEOUS NUCLIDES. Schmeling, Per Erik (to Aktiebolaget Atomenergi). British Patent 1,242,450. 11 Aug 1971. Filed 8 Nov 1968.

A method is described for the production of gaseous radionuclides from neutron-irradiated target materials, such as ^{133}Xe from irradiated U; it is claimed to be less complicated and more reliable than some other methods in use, and to be suitable for commercial production. It comprises melting the target material with a fluxing agent to produce a comparatively low-melting fluxed target, enclosing this target in a gas-tight container, and irradiating in a nuclear reactor. The container and contents are then heated until the contents are molten, thus releasing the gaseous nuclides, followed by placing the gaseous phase in communication with a suitable gas-recovery apparatus, which may consist of a closed evacuated system containing an appropriate adsorption agent. An example of a suitable fluxed U target is the mixture of molten salts produced by dissolving UO_2 in molten sodium pyrosulphate; this has a melting point of 500° to 600°C, is readily soluble in water, and can achieve 30% by weight of U. A liquid-nitrogen-cooled carbon trap may be used in the adsorption system, giving nearly pure ^{133}Xe on desorption. (UK)

57486 ^{52}Fe: IMPROVING ITS RECOVERY FROM CYCLOTRON TARGETS. Thakur, M. L.; Nunn, A. D.; Waters, S. L. (Hammersmith Hospital, London). Int. J. Appl. Radiat. Isotop.; 22: No. 8, 481-3(Aug 1971).

Previous methods of recovering ^{52}Fe from cyclotron targets and their shortcomings are briefly reviewed. A modified chromium target system and a simplified solvent extraction method, for which >98% ^{52} Fe recovery is ensured, are described. The advantages of this method are noted and variations in the extraction technique, with their retrieval percentages, explained. Higher extraction efficiency results after boiling the etch solution, and possible reasons for this are discussed. Use of a 15-cc Ge(Li) detector to assess the efficiency of individual steps is noted. (UK)

Recoil Production and Reactions

Refer also to abstracts 57456, 57501, and 57503.

57487 (COO-1713-25) REACTION STUDIES OF HOT SILICON AND GERMANIUM RADICALS. Progress Report, September 1, 1970–August 31, 1971. Gaspar, Peter Paul (Washington Univ., St. Louis, Mo. Dept. of Chemistry). Contract AT(11-1)-1713. 14p. Dep. NTIS.

Research progress is reported on the following topics: product-forming steps in the reactions of recoil silicon atoms, primary reactions of recoiling silicon atoms, reactions of recoiling germanium atoms, and kinetics of silyl radical reactions and flow-discharge production of Si, Ge, and C atoms. (D.H.M.)

57488 CHEMICAL CONSEQUENCES OF THE REACTION $^{238}U(n,\gamma)^{239}U$ IN URANIUM SULFATES AND ACETATES. Heitz, Ch.; Ruffenach, J. C. (Centre de Recherches Nucleaires, Strasbourg). Radiochem. Radioanal. Lett.; 7: No. 5-6, 319-24(10 Sep 1971). (In French).

The oxidation states of ^{239}U formed by the $^{238}U(n,\gamma)$ reaction in uranyl and uranous sulfates and acetates were measured. Effects of secondary oxidation and isotope exchange reactions are discussed. (auth)

57489 EFFECTS OF THERMAL NEUTRON CAPTURE IN PLATINUM ACETYLACETONATE. Belgrave, E. (Centre de Recherches Nucleaires, Strasbourg). Radiochem. Radioanal. Lett.; 7: No. 5-6, 325-9(10 Sep 1971).

A study of the chemical consequences of neutron capture in platinum acetylacetonate revealed an important isotope effect. (auth)

57490 THERMAL ANNEALING AND SOLID STATE ISOTOPE EXCHANGE OF ^{51}Cr IN POTASSIUM TRISOXALATO CHROMATE-(III) TRIHYDRATE. Kishore, K.; Venkateswarlu, K. S. (Bhabha Atomic Research Centre, Trombay, India). Radiochem. Radioanal. Lett.; 7: No. 5-6, 263-8(10 Sep 1971).

Neutron-irradiated potassium trisoxalato chromate(III) trihydrate yields four radioactive species after dissolution. The presence of a ligand-deficient species and the change in its yield on annealing at lower temperatures suggest a stepwise mechanism for the annealing reaction. Doping of the nonirradiated complex with ^{51}Cr and the following of the Cr exchange also indicate the presence of ligand-deficient intermediate species. The exchange reaches about 80%. (auth)

57491 DIFFERENCES BETWEEN THE REACTIONS OF GASEOUS CH_4 WITH ^{80}Br AND ^{82}Br ACTIVATED BY ISOMERIC TRANSITION. Yagi, M.; Kondo, K.; Kobayashi, T. (Tohoku Univ., Sendai). Radiochem. Radioanal. Lett.; 7: No. 5-6, 275-80(10 Sep 1971).

The reactions of ^{80}Br and ^{82}Br, activated by the isomeric transition, with gaseous CH_4 were compared with each other. It was confirmed that the total organic yields in the $CH_4-{}^{80m}BrBr$ system are much higher than those in the $CH_4-{}^{82m}BrBr$ system. This difference is attributed to the consecutive, two-step internal conversion process in the cascade de-excitation of ^{80m}Br. (auth)

57492 DIFFERENCES BETWEEN THE REACTIONS OF GASEOUS CH_3Br WITH ^{80}Br AND ^{82}Br ACTIVATED BY ISOMERIC TRANSITION. Shiokawa, T.; Kobayashi, T.; Kondo, K.; Yagi, M. (Tohoku Univ., Sendai). Radiochem. Radioanal. Lett.; 7: No. 5-6, 281-6(10 Sep 1971).

The reactions of isomeric transition-activated ^{80}Br in the $CH_3Br-{}^{80m}BrBr$ system were compared with those in the $CH_3Br-{}^{82m}BrBr$ system. The organic yields and the highly brominated product yields in the former system were found to be higher than those in the latter system. These facts suggest that there are fundamental differences between the reactions of ^{80}Br and ^{82}Br, activated by the isomeric transition, with gaseous CH_3Br. (auth)

57493 ISOTOPE EXCHANGE AND THERMAL ANNEALING OF RECOIL DAMAGE IN TRISOXINATOCOBALT(III). Venkateswarlu, K. S.; Anthony, M. C.; Ramshesh, V. (Bhabha Atomic Research Centre, Trombay, India). Radiochem. Radioanal. Lett.; 7: No. 5-6, 259-62(10 Sep 1971).

Trisoxinatocobalt(III) was investigated for thermal annealing following neutron capture, and for isotope exchange with $^{58}Co^{2+}$, both in the presence and absence of oxygen. (auth)

57494 $^{80m}Br/I.T./^{80}Br$ REACTIONS IN INORGANIC BROMIDE–HYDROCARBON SYSTEMS. I. VARIATION OF THE ORGANIC YIELD WITH THE INORGANIC BROMIDE. Mohan, H.; Iyer, R. M. (Bhabha Atomic Research Centre, Trombay, India). Radiochem. Radioanal. Lett.; 7: No. 5-6, 381-5(10 Sep 1971).

If ^{80m}Br present as NH_4Br, $MgBr_2$, $CaBr_2$, $ZnBr_2$, $SrBr_2$ or $HgBr_2$ undergoes isomeric transition reactions in n-hexane, the observed organic yields do not follow the trend expected from differences in kinetic energy of the ejected ^{80}Br. It was concluded that the resultant positive charge on ^{80}Br at the time of its break from its original partner determines the final chemical stabilization of the radioactive atom. (auth)

57495 HOT-ATOM CHEMISTRY OF POLYPHOSPHATES. IV. RADIATION EFFECT ON THE OXIDATION STATE OF ^{32}P IN AQUEOUS PHASE. Matsuura, Niro; Lin, Tsing-ko (Tokyo Univ.). J. Inorg. Nucl. Chem.; 33: No. 8, 2281-9(Aug 1971).

Tripolyphosphate solution with various scavengers such as phosphite, hypophosphite, formate, and benzene was irradiated in the reactor. The radioactive yields of hypophosphite (^1P), phosphite (^3P), and phosphate (^5P) as well as diphosphite ($^2P-{}^4P$) and hypophosphate ($^4P-{}^4P$) depended on the irradiation time and the scavenger used. The recoil ^{32}P species that had a mean oxidation state of +2 at zero γ-dose were mainly composed of ^1P and ^3P species; however, both H and OH radicals produced from the γ radiolysis of water oxidized ^1P to ^3P and ^3P to ^5P through the intermediate states of ^2P and ^4P, respectively. On the basis of these observations, the reaction mechanism of ^{32}P in the aqueous phase was also discussed. (auth)

57496 TRANSFER ANNEALING IN CHROMIUM(III) TRISACETYLACETONE. Gainar, I.; Ponta, A. (Inst. for Atomic Physics, Bucharest). J. Inorg. Nucl. Chem.; 33: No. 8, 2291-2300(Aug 1971).

A comparative study of the thermal transfer, or exchange, in $^{51}Cr(III)$-doped chromium trisacetylacetone crystals and the thermal annealing in the neutron-irradiated crystals was carried out. Quite different thermal behaviors were found in the case of Cr. $acac_3$-crystals, doped with the ^{51}Cr species present in a methanolic solution of $^{51}CrCl_3$ and the undoped crystals. The thermal transfer in Cr. $acac_3$ crystals doped with the ^{51}Cr species present in a methanolic fraction obtained as a recoil product was quite similar to the thermal annealing in the neutron-irradiated crystals. A ligand transfer mechanism is suggested to account for such behavior. (auth)

57497 BEHAVIOR OF RADIOACTIVE RHENIUM ATOMS IN THE THERMAL ANNEALING OF CRYSTALLINE RHENIUM SALTS, IRRADIATED WITH 660 MeV PROTONS. Zaitseva, N. G.; Ianovich, E. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 103-7(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 107-13(Jan-Feb 1971).

The influence of thermal annealing on the chemical behavior of rhenium recoil nuclei, formed in the irradiation of sodium perrhenate and potassium hexachlororhenate crystals with 660-MeV protons, was studied. The behavior of radioactive rhenium depends on the chemical form of the irradiated compound: competing reactions of reduction and oxidation take place in $NaReO_4$ crystals, while processes of reduction of rhenium corresponding to the classical shape of the isothermal annealing curves take place in K_2ReCl_6 crystals (the fast step of the reduction of radiorhenium and a slower step with pseudoplateau). On the basis of the results of a kinetic investigation of the thermal annealing of K_2ReCl_6 crystals, the rate of reduction of radioactive rhenium, activation energy, and order of the reaction were determined for the

XUM

fast step of the process. The behavior of radiorhenium in the thermal annealing of K_2ReCl_6 crystals, irradiated with 660-MeV protons and thermal neutrons, is the same, which is an indication of independence from the recoil energy. The mechanism of the behavior of radioactive rhenium atoms in thermal annealing is discussed from the standpoint of the interaction of recoil atoms with defects of the lattice of the irradiated crystals. 57498 (CONF-711002–, pp 283-92) SAMPLING AND DILUTION PROBLEMS IN RADIOACTIVITY MEASUREMENTS. van der Eijk, W.; Vaninbroukx, R. (European Atomic Energy Community, Geel (Belgium). Central Nuclear Measurements Bureau). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Techniques for achieving minimal errors introduced by dilution and sampling in the preparation of radioactivity standards are discussed. The two techniques employed at the Central Bureau of Nuclear Measurements in Geel, Belgium, namely gravimetric and volumetric methods, are discussed. Stability of solutions and sources are also considered. It was concluded that in the calibration of radioactive solutions, errors due to sampling and dilutions can be kept below 0.03% for drop masses of about 100 mg and below 0.07% for drop masses of about 20 mg, provided that the weights can be calibrated with sufficient accuracy. (D.H.M.)

57499 FORMATION OF IODIDES IN SOLID BUTANE IRRADIATED BY I^+ IONS. Cailleret, J.; Abbe, J. Ch.; Paulus, J. M. (Centre de Recherches Nucleaires, Strasbourg). Radiochem. Radioanal. Lett.; 7: No. 5-6, 331-7(10 Sep 1971). (In French).

An ion generator was built in order to study the reactions of a solid butane target with 3000- to 50-eV I^+ beams. The analysis is performed by gas chromatography and the following products are generated: ICH_3, IC_2H_5, n-IC_3H_7, s-IC_4H_9, n-IC_4H_9. The organic yields and the distribution are energy dependent. (auth)

57500 FAST PREPARATION METHOD OF ^{32}P APPLICATORS. Svobodova, J. (Vyzkumny Ustav pro Vyuziti Radioisotopy v Lekarstvi, Prague); Kolinska, J.; Kronrad, L. Radioisotopy; 11: No. 3, 447-56(1970). (In Czech).

A fast and simple preparation method of ^{32}P applicators for clinical use was developed. The applicators are made by sorption of ^{32}P-labeled sodium phosphate ^{32}P-labeled phosphoric acid on Anex foil Zerolith FF. The detailed experimental procedure and sorption conditions are described. (auth)

57501 SOME EXPERIMENTAL DATA CONFLICTING WITH THE EXPLOSION MODEL IN GASEOUS BROMIDES. Takita, Y.; Hiraga, M.; Yoshihara, M.; Shiokawa, T. (Tohoku Univ., Sendai). Radiochem. Radioanal. Lett.; 7: No. 5-6, 313-18(10 Sep 1971).

Some experimental results that qualitatively conflict with the "explosion model" proposed by Carlson and White were obtained in the x-ray irradiation of gaseous bromides and in the isomeric transition of ^{80m}Br-labeled methyl bromide. The hydrogen-deficient species, such as CH_2Br^+, $CHBr^+$, and CBr^+, were detected in addition to the parent ion CH_3Br^+ after the isomeric transition. Limitations of the "explosion model" are discussed. (auth)

57502 DEVICE FOR THE SAFE HANDLING OF TRITIUM GAS. den Hollander, W. (Vrije Univ., Amsterdam). Radiochem. Radioanal. Lett.; 7: No. 5-6, 345-50(10 Sep 1971).

A device for tritium handling is described, which has three distinct advantages: (1) Tritium gas is stored as uranium tritide behind a palladium diffusion tube in a completely sealed vessel. The palladium tube ensures chemical purity of the tritium gas. (2) A specially designed gas burette is connected to the storage vessel. The amounts of gas can be determined before and after use. (3) Tritium gas is transferred from gas burette to reaction vessel and vice versa with the aid of a Toepler pump. The tritium gas in the reaction vessel can be pressurized up to 3 atmospheres. (auth)

57503 CHEMICAL EFFECTS OF NUCLEAR TRANSFORMATIONS IN THE ALKALI CHLORIDES. PART 3. BEHAVIOUR OF ION IMPLANTED ^{35}S. Kasrai, M.; Maddock, A. G.; Freeman, J. H. (Cambridge Univ., Eng.). Trans. Faraday Soc.; 67: No. 583, 2108-16(Jul 1971).

The valence distribution of ion-implanted ^{35}S in sodium chloride was investigated and the influences of pre-bombardment of the crystal with O, S, and Cl measured. The effects of pre- or post-irradiation of the crystals with γ radiation and of thermal annealing combined with these treatments were examined. A small part of the ^{35}S penetrates deeply into the crystal, giving a supertail to the distribution. This phenomenon is attributed to interstitial diffusion and the valence distribution of this sulphur was measured. (auth)

57504 SYSTEM FOR THE PRODUCTION AND STUDY OF BROMINE DELAYED NEUTRON PRECURSORS FROM FISSION. Mitsonias, C. A.; Perricos, D. C. (Democritus Nuclear Research Center, Athens). Radiochim. Acta; 15: No. 4, 187-90(Jun 1971).

A system is described for the fast separation of bromine delayed neutron precursors from fission products, based on gas sweeping of a uranium solution in concentrated sulfuric acid. The system was developed for the study of the delayed neutron energy spectrum by a time-of-flight $\beta-n$ coincidence technique and is fully automated. (auth)

57505 ABSOLUTE ACTIVITY MEASUREMENT OF ^{3}H. Kokta, L.; Kits, J.; Bucina, I.; Novotna, P. (Ustav Pro Vyzkum, Vyrobu a Vyuziti Radioisotopu, Prague). Radioisotopy; 11: No. 5, 953-71(1970). (In Czech).

On the basis of experiences with absolute determination of ^{14}C a method of absolute activity measurement of ^{3}H was proposed and realized. Tritiated water forming the standard solution is reduced with zinc powder in a sealed ampoule at 600°C. The active hydrogen thus formed is completed with methane to atmospheric pressure and after mixing with a Toeppler pump measured by three internal proportional counters of various lengths. The specific activity of the standard solution is determined on the basis of counting rate distribution in two counters with relation to volume difference and corrections are made for the wall effect, discrimination threshold, dead time of the measuring device, background, and conversion efficiency to active gas. The standard deviation from the specific activity established in this way is ±0.53% which corresponds to a maximum error of ±1.6%. (auth)

57506 EVALUATION METHOD OF THE GAMMA SPECTROMETRICAL DETERMINATION OF RADIUM IN STATE OF NONEQUILIBRIUM. Thomas, J.; Malatova, I. (Vyzkumny Ustav Hygieny Zareni, Prague). Radioisotopy; 11: No. 5, 815-21 (1970). (In Czech).

A method of analysis of a time-dependent multicomponent spectrum of radium and its decay products in a state of nonequilibrium is described. The method is based on the multidimensional nonlinear regression spectral analysis leading simultaneously to the determination of the counting efficiency coefficients of the individual components and of their activities. In routine measurements of the preparation under identical measurement conditions it is possible to apply once for ever the determined measurement coefficients and to determine the activity of the spectrum components by linear multidimensional regression analysis. The method of simultaneous determination of detection coefficients in initial activities described is applicable to mixtures with time to variable activities. (auth)

Separation Processes

57507 (ANL-7799) CHEMICAL ENGINEERING DIVISION FUEL CYCLE TECHNOLOGY QUARTERLY REPORT, JANUARY–MARCH 1971. Webster, D. S.; Jonke, A. A.; Bernstein, G. J.; Levitz, N. M.; Pierce, R. D.; Steindler, M. J.; Vogel, R. C. (Argonne National Lab., Ill.). Jul 1971. Contract W-31-109-eng-38. 71p. Dep. NTIS.

During the period January through March, 1971, work was done in the following areas: (1) further development of a liquid-metal head-end process for LMFBR fuel by study of the reduction of declad fuel oxide, (2) investigation of a procedure for separating stainless steel cladding from fuel oxide by melting the cladding, (3) additional laboratory-scale work to develop a fluid-bed process for the conversion of uranyl nitrate and plutonium nitrate in nitric acid solutions to an oxide form (UO_2-PuO_2) suitable for the fabrication of fuel shapes for LMFBR fuel, (4) additional development of x-ray diffraction spectrometry as an in-line analytical method for determining the Pu/U ratio of oxide fuels during fabrication, (5) continued investigation of the performance characteristics of a centrifugal contactor for plutonium isolation steps in the solvent extraction of LMFBR fuels, and (6) study of electrode reactions and process parameters that affect the electrolytic reduction and reoxidation of plutonium in the Purex process. (auth)

57508 (ANL–7810) DEVELOPMENT OF A MIXER-SETTLER FOR LIQUID METAL-SALT SYSTEMS. Knighton, J. B.; Bernstein, G. J.; Vargo, G. N.; Pierce, R. D. (Argonne National Lab., Ill.). Jun 1971. Contract W-31-109-eng-38. 49p. Dep. NTIS.

A single-stage mixer-settler was developed for application in a multistage extraction process to extract plutonium from spent LMFBR fuel material. This device is designed to separate plutonium from fission products by salt extraction and salt transport procedures. (Salt transport is selective transfer of a solute from a liquid donor alloy to a liquid acceptor alloy by circulating molten salt between the two alloys.) The design of the unit fabricated provides for contacting of two liquid phases in a mixing chamber by blades on the outside of a hollow agitator-pump rotating in the mixing chamber; the mixture is then pumped through the interior of the mixer-pump to discharge openings at its top, from which the mixture is routed as required for a particular application. Preliminary tests with a 5-cm-OD, 20-cm-long stainless steel mixer-pump showed it to be capable of pumping Mg–Cu alloy at 670°C. However, mixing blades at the bottom of the mixer-pump failed to provide sufficient agitation. A second stainless steel mixer-pump was fabricated. This pump employed a stepped cylindrical wall with mixing blades attached to the outer surface of the pump near its bottom. A mixing chamber design was developed whereby gas entrainment in the mixing chamber was eliminated. In runs with water only, flow rate was related to pump speed, the size of the inlet orifice in the bottom of the pump, and the depth of water on the outside of the pump (pump submergence). The residence time distribution for water flowing through the mixing chamber was also studied. High-temperature runs were performed with the mixer-pump installed in an assembly containing a settling chamber, all within a sealed heated vessel. Metal flow rates were successfully measured with a metering cup and an induction liquid-level probe. To measure extraction efficiency, tagged cerium was extracted from Mg–Cu alloy into chloride salts at 650°C. Stage efficiencies above 99% were achieved. The overall mechanical performance of the single-stage mixer-settler was considered satisfactory. (auth)

57509 (ARH-SA–58) MACRORETICULAR ION EXCHANGE RESIN CLEANUP OF PUREX PROCESS TBP SOLVENT. Schulz, Wallace W. (Atlantic Richfield Hanford Co., Richland, Wash.). 1 Aug 1970. 27p. Dep. NTIS.

This report appeared in rough draft form in NSA 25: 34679 as ARH-SA-58-RD (CONF-710417-2). (D.H.M.)

57510 (ARH-SA–82) CONTROL OF A CONTINUOUS ION EXCHANGE SYSTEM. Hobart, R. L. (Atlantic Richfield Hanford Co., Richland, Wash.). 20 Oct 1970. Contract AT(45-1)-2130. 18p. (CONF-701022–2). Dep. NTIS.

From Regional meeting of the AIChE; Richland, Wash. (23 Oct 1970).

The control system that is necessary to operate the continuous anion exchange equipment used in the purification of plutonium at the Hanford Purex Plant is described, including process description, resin "push" system and controls, absorption-scrub column, elution column, programmer, alpha monitors, and operating history. (D.H.M.)

57511 (BNWL-B–121) DESTRUCTION OF NITROUS ACID AND HYDRAZOIC ACID IN PUREX SYSTEMS. Swanson, J. L. (Battelle Pacific Northwest Labs., Richland, Wash.). Aug 1971. Contract AT(45-1)-1830. 13p. Dep. NTIS.

Most of the hydrazoic acid formed in the Purex process is present in the organic phase until it is removed as azide ion by the carbonate wash in the organic recovery process. Destruction of the azide ion in the carbonate solution can be accomplished by platinum-catalyzed hydrazine reduction. Azide destruction can be accomplished in several ways in acid solution; the most promising method for use at Hanford is the reaction with permanganate following acidification of the mixed permanganate–carbonate solvent wash solution. Elimination of nitrous acid from the organic stream fed to the partition column (the 1BXF solution) would markedly reduce if not eliminate hydrazoic acid formation in the 1BX column. Several ways of accomplishing this were demonstrated; the most promising method for plant application is the reaction with hydroxylamine before the organic stream is fed to the column. (auth)

57512 (DOCKET-50201–87) WEST VALLEY REPROCESSING PLANT. Technical Specifications, Change No. 15. (Division of Materials and Licensing (AEC), Washington, D. C.). 24 Sep 1971. 36p. Dep. NTIS.

The publication "Technical Specifications of License No. CSF-1" was revised to incorporate Technical Specifications related to operation of the main plant and to the low-level liquid waste treatment plant and to discharge of effluents to the watershed. Reporting requirements in connection with operation of the low-level waste treatment plant are listed. Safety evaluations of the waste treatment facility are given. (M.C.G.)

57513 (DOCKET-50201–88) WEST VALLEY REPROCESSING PLANT. Final Safety Analysis Report, Revised Tornado Missile Analysis. (Nuclear Fuel Services, Inc., Rockville, Md.). 23 Sep 1971. 6p. Dep. NTIS.

A revised tornado missile analysis is presented, which uses a pressure drop of 3 psi in 3 sec during tornado passage. (M.C.G.)

57514 (DOCKET-50201–89) WEST VALLEY REPROCESSING PLANT. Addendum to Safety Evaluation for Transfer and Processing of Plutonium Nitrate–Uranyl Nitrate Solutions. (Nuclear Fuel Services, Inc., West Valley, N. Y.). 15 Oct 1971. 5p. Dep. NTIS.

Details of transfer and processing of plutonium nitrate–uranyl nitrate solutions are modified and expanded. Topics covered include: transfer to the dissolver, feed adjustment and accountability, and solvent extraction processing. (M.C.G.)

57515 (DOCKET-50268–15) MIDWEST FUEL RECOVERY PLANT. Amendment No. 18, Supplement No. 1 to Amendment No. 15. (General Electric Co., San Jose, Calif. Nuclear Fuel Dept.). 20 Aug 1971. 38p. (NEDO–10178–4). Dep. NTIS.

Information is presented in support of the request for authorization of activities requiring source, special nuclear, and by-product materials. (M.C.G.)

57516 (DOCKET-50332–20) BARNWELL NUCLEAR FUEL PLANT. Reasons Why the Construction Permit Should Not Be Suspended Pending Supplemental Environmental Review. (Allied-Gulf Nuclear Services, Barnwell, S. C.). 11 Oct 1971. 244p. (EMP–100; EMP–101). Dep. NTIS.

An environmental impact program for the Barnwell Nuclear Fuel Plant and an analysis of the impact of the plant's liquid discharges on Lower Three Runs Creek are presented. Reasons for not suspending the construction permit are listed. (M.C.G.)

57517 (DP–1266) REMOTE DECONTAMINATION OF EQUIPMENT IN A RADIOCHEMICAL SEPARATIONS PLANT. Hill, A. J. (Du Pont de Nemours (E. I.) and Co., Aiken, S. C. Savannah River Lab.). Sep 1971. Contract AT(07-2)-1. 33p. Dep. NTIS.

At the Savannah River Plant, process equipment from the radiochemical separations plants is decontaminated rapidly and economically by scouring with high-velocity jets of water and by applying dilute solutions of simple reagents at elevated temperatures. The decontamination, disassembly, and some maintenance and auxiliary work are done by remote operation to minimize exposure of personnel to radiation. In over five years of operation, this technique made possible the salvage and repair of much valuable equipment and significantly reduced radiation exposure during maintenance work. (auth)

57518 (EURFNR–888) AQUEOUS REPROCESSING OF FAST BREEDER FUEL ELEMENTS. COMMON EXTRACTION AND SEPARATION OF MACROQUANTITIES OF PLUTONIUM AND URANIUM IN THE PUREX PROCESS. Ochsenfeld, W.; Schmieder, H.; Theiss, S. (Kernforschungszentrum, Karlsruhe (West Germany). Institut fuer Heisse Chemie). Translation of report KFK–911. 104p. Dep. NTIS.

Work Performed under United States–Euratom Fast Reactor Exchange Program.

For the reprocessing of irradiated fast breeder fuel elements by solvent extraction with 20% TBP–alkane, coextraction, cobackwash, and partitioning of uranium and plutonium were studied. In the coextraction and cobackwash countercurrent experiments, losses of plutonium and uranium to the aqueous raffinate (HAW) and to the organic extractant (HCW) remained below 0.1%. Partitioning of plutonium and uranium by reduction with uranium(IV) was studied intensively, and compared with reduction by ferrous sulfamate. Countercurrent experiments resulted in plutonium losses to the uranium stream (1BU) of less than 0.2%, while the decontamination of the plutonium product (1BP) from uranium yielded a decontamination factor of $\sim 10^3$. (auth)

57519 (IN–1484) PROCESS CHEMISTRY FOR BURNER PRODUCT FROM GRAPHITE FUELS CONTAINING NIOBIUM. Paige, B. E.; Evans, T. L. (Idaho Nuclear Corp., Idaho Falls). Jun 1971. Contract AT(10-1)-1230. 32p. Dep. NTIS.

A burn-leach process is being developed for reprocessing Rover rocket fuels at the Idaho Chemical Processing Plant. Data are reported for an aqueous process for recovering uranium from the HNO_3-soluble oxide in the burner product and also from the HNO_3-insoluble uranium, Nb_3UO_{10}, which forms during combustion. Dissolution rates of Nb_3UO_{10} and of Nb_2O_5 from overhead product increased with increasing fluoride concentration both for various concentrations of hydrofluoric acid and for mixtures of hydro-

XUM

fluoric acid–nitric acid. Solubility of uranium in the dissolver product and the species precipitated are discussed. A stable region for Nb–Al–F solutions is defined. The corrosion of stainless steel is evaluated with respect to the degree of complexing of the fluoride by niobium. A dilute uranium dissolver product with minimum fluoride-to-niobium mole ratio, completely complexed at 0.4 M aluminum or less, is the best extraction feed from the standpoint of stability and corrosion of extraction equipment. (auth)

57520 (JINR–E6-5952) ELECTROMIGRATION SEPARATION OF TRANSURANIUM ELEMENTS IN SOLUTIONS OF ETHILENDIAMINTETRACETIC AND CYCLOHEX ANDIAMINTETRACETIC ACIDS. Buklanov, G. V.; Korotkin, Yu. S. (Joint Inst. for Nuclear Research, Dubna (USSR). Lab. of Nuclear Reactions). 1971. 8p. Dep. NTIS (U. S. Sales Only).

Electromigration separation of a mixture of transuranium elements in solutions of EDTA and CDTA was carried out. Clear separation of Am and Cm was achieved. Electromigration behavior of Po, Ac, Th, Pa, and Ra under the same conditions was investigated. The possibility of fast separation of microquantities of transuranium elements and milligrams of lanthanum is shown. (auth)

57521 (KURRI-TR–76, pp 15-18) RAPID CHEMICAL SEPARATION. Kusaka, Yuzuru (Kyoto Univ. (Japan). Research Reactor Inst.). (In Japanese).

From Meeting on nuclei with short life; Osaka, Japan (30 Jun 1969).

In Reports of the study meeting on nuclei with short life.

A proper separation method in radiochemistry is a method to obtain elements with high purity and large yield within a short time in comparison with lifetime of the elements. The following factors determine the mode of separation: chemical and physical properties of the nuclide to be separated, half-life of the nuclide, kinds and amounts of nuclides existing together, and daughter nuclei in decay series. The mode is classified by half-life as superfast ($T_{1/2} < 1$ min), fast (1 min $< T_{1/2} < 20$ min), and conventional ($T_{1/2} > 20$ min). Steps of the fast separation are preparation of a target, irradiation, transportation of the target, separation (gas separation, recoil method, extraction, ion-exchange method, precipitation or electrochemical separation), preparation of samples to be measured, and measurement of yield. When the life-time is very short, e.g., less than 1 min, all the steps of the separation should be finished within 1 min. In this case, the separation in the gas phase or the recoil method is applied, and the on-line or loop method is employed for the transportation. Steps of the gas phase separation are phase transfer, gas sweeping, and gas collection. Hot atoms produced by nuclear reaction have large recoil energy, and emerge from the target spontaneously. Separation of Kr and Xe has been studied, and many experiences were reported. A distillation method is used to separate volatile elements or compounds. Separated gas is collected by condensation, absorption, pyrolysis, chemical fixation, or electrostatic collection. (Japan)

57522 (ORNL–4676, pp 234-71) MOLTEN-SALT PROCESSING AND PREPARATION. (Oak Ridge National Lab., Tenn.). Aug 1971.

REACTOR FUELS—reprocessing of molten salt, flowsheet analysis for
THORIUM—solubility in lithium–bismuth solutions
URANIUM—separation from MSBR fuel by fluoride volatility process, flowsheet analysis for
—separation from MSBR fuel by oxide precipitation (M.C.G.)

57523 (ORNL–4677) RADIOACTIVE CONTAMINATION OF COPPER RECOVERED FROM ORE FRACTURED WITH NUCLEAR EXPLOSIONS. Arnold, W. D.; Crouse, D. J. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 55p. Dep. NTIS.

Results of laboratory tests simulating the processing of copper ore after fracturing with nuclear explosives indicate that only very small fractions of the radioactive fission products and neutron activation products will be dissolved on leaching with sulfuric acid. Tritium (as tritiated water) will be, by far, the dominant radionuclide in the circulating leach liquor, assuming use of a fusion device. Copper that was recovered from the leach solution by cementation was significantly contaminated with ^{106}Ru. The ^{106}Ru was rejected effectively in electrolytic purification; therefore, the final copper product should be very weakly radioactive and not hazardous to the customer. However, the radioactivity level may be high enough to make the copper unsuitable for some specific uses. The tritiated water in the leach liquor and the ^{106}Ru in the cement copper are potential problems at the plant site and should be carefully considered in the design and in the operation of the facility. However, since the radioactivity levels would be low, adequate protection for the operating personnel should be neither difficult nor costly to provide. Results of these tests showed that the use of solvent extraction as an alternative to cementation for recovering copper from the leach liquor would have important advantages. Since copper is efficiently separated from radionuclides in the extraction step, radioactivity in the processing operations beyond the extraction contactors should be negligible. The radioactivity level of the final copper product recovered from the solvent extraction strip solution by electrowinning should be almost undetectable; therefore, marketing of the copper should not present any difficulties. Because of the superior marketability of the product and the much simpler radiation control problems at the processing site, use of the solvent extraction—electrowinning flowsheet is recommended. (auth)

57524 (ORNL-TM–3343) SUMMARY OF THE CAMPAIGN DURING FEBRUARY 1969 TO PROCESS SIX IRRADIATED HFIR TARGETS IN THE TRANSURANIUM PROCESSING PLANT. King, L. J.; Collins, E. D. (Oak Ridge National Lab., Tenn.). Aug 1971. Contract W-7405-eng-26. 45p. Dep. NTIS.

Six irradiated HFIR targets were processed in the Transuranium Processing Plant (TRU) to recover the transuranium elements. This was the first campaign in which recycle americium–curium targets were processed. Prior to irradiation, each of the targets contained approximately 4.38 g of ^{244}Cm, 0.34 g of heavier curium isotopes, and 0.78 g of ^{243}Am that had been recovered in TRU from irradiated plutonium targets. The six targets had been fabricated in the remote target fabrication equipment in TRU, using americium–curium oxide powder, which had been prepared during development studies of the curium sol-gel process. Purified products contained about 0.3 g of ^{243}Am, 17 g of ^{244}Cm, 1.2 mg of ^{249}Bk, 9.2 mg of ^{252}Cf, 68 μg of ^{253}Es and 10^8 atoms of ^{257}Fm. Processing steps were: dissolution of the aluminum using caustic–nitrate solution, dissolution of the actinide oxides using concentrated hydrochloric acid, removal of radioiodine and recovery of plutonium using a batch solvent extraction process (Pubex), decontamination of the transplutonium elements using the Tramex solvent extraction process, and separation of americium and curium from the transcurium elements using a LiCl-based anion exchange process. The transcurium elements were separated and purified using laboratory-scale equipment installed in one of the processing cells. Newly-installed metal (tantalum) equipment for the LiCl-based anion exchange process performed satisfactorily. All product fractions were taken based on continuous in-line alpha monitoring of the column effluent line and on neutron and gamma scans of the tantalum column. Only 300 millicuries of ^{131}I (of 400 curies present in the targets) were released from TRU during the campaign. Most of the iodine-bearing off-gas was confined to a 3-cfm stream, and an experimental iodine removal system was installed in this small stream. The treatment system was composed of a caustic scrubber to remove acid vapors, a heater, a bed of oxidation catalyst (operated at 350°C), a cooler, and a bed of KI-impregnated charcoal. The 3-cfm off-gas stream was decontaminated from ^{131}I by a factor (DF) as high as 10^4. (auth)

57525 (RFP–1723) EVALUATION OF METHODS TO RECOVER PLUTONIUM FROM INCINERATOR ASH. Ziegler, Donald L.; Lindsay, John W.; Fraser, John K. (Dow Chemical Co., Golden, Colo. Rocky Flats Div.). 16 Aug 1971. Contract AT(29-1)-1106. 10p. Dep. NTIS.

Laboratory experiments were performed to evaluate the methods of hydrochloric acid leaching, nitric acid leaching, various fusion-leaching, and fluorination-leaching used for removal of plutonium from incinerator ash and residue from leached incinerator ash. Three precipitation methods were evaluated for removing the plutonium from a hydrochloric acid solution. The results indicate that the hydrochloric leaching of ash, coupled with a lanthanum fluoride-carried precipitation, is superior to other methods tested from recovering plutonium from incinerator ash. 57526 (UCRL–73190(Rev.1)) LIQUID CHROMATOGRAPHY. I. HIGH SPEED SEPARATION OF THE RARE EARTHS. Sisson, D. H.; Mode, V. Alan (California Univ., Livermore. Lawrence

Radiation Lab.). May 1971; Revised Aug 1971. 13p. (CONF-710711-2). Dep. NTIS.

From fourth conference on liquid chromatography; Los Angeles, Calif. (8 Jul 1971).

A high-pressure liquid chromatographic technique using α-hydroxyisobutyric acid as eluant is presented that will allow rare earth separation, Lu through La, in three to four hours. (D.H.M.)

57527 (UJV-2557-Ch) PARTITION CHROMATOGRAPHY OF URANIUM AND FISSION PRODUCTS ON POROUS STYRENE-DIVINYLBENZENE COPOLYMER SWOLLEN IN THE SOLUTION OF TRIBUTYLPHOSPHATE. III. PROPERTIES OF COPOLYMER AS CARRIERS OF STATIONARY PHASE AND PREPARATION OF SWOLLEN GELS. Literature Survey. Beranova, H.; Tejnecky, M. (Ceskoslovenska Akademie Ved, Rez. Ustav Jaderneho Vyzkumu). Jun 1971. 38p. Dep. NTIS (U. S. Sales Only).

The literature concerning partition chromatography is surveyed. Properties of styrene–divinylbenzene copolymers as carriers of stationary phase are evaluated. The preparation of swollen gels and the concentration of tributyl phosphate in swollen gels were studied in relation to the tributyl phosphate concentration in the swelling agent, diluent type, and divinylbenzene content in standard (S) and macroporous (P) copolymers. Porous copolymers were convenient as carriers of the organic phase in accordance with the original assumption. The effects of surfaces or pore volume of porous copolymers were determined for some compounds that did not swell the copolymers. The sorption of nitric acid and hydrochloric acid was examined for the concentration range in the liquid phase 1 to 8M. The heats of swelling were measured for chosen copolymer–diluent system and the results were applied for the swelling process evaluation. (112 references). (auth)

57528 (UR–3999-11) CALCULATION OF SOME ISOTOPE SEPARATION FACTORS FOR CHEMICAL EXCHANGE, DISTILLATION, EXCHANGE DISTILLATION, AND ABSORPTION USING $UF_{6(g)}$. Bigeleisen, Jacob (Rochester Univ., N. Y. Dept. of Chemistry). [1971]. Contract AT(30-1)-3999; Subcontract 3234. 18p. Dep. NTIS.

The reduced partition function of $({}^{238}UF_6/{}^{235}UF_6)_g$ was calculated from the vibrational potential function of Claassen in good agreement with a previous calculation by Mayer and Bigeleisen. Implications of this calculation with respect to chemical exchange reactions of $UF_{6(g)}$ with complexes of UF_6 are discussed. The quantum mechanical theorem of corresponding states and the vibrational spectra of $UF_{6(g)}$, $UF_{6(l)}$, and UF_6 dissolved in C_7F_{16} were used to calculate $\ln(f_c/f_g)$ in the liquid and solution. These lead to $\ln\alpha$ values for distillation and absorption of -4×10^{-5} and -6×10^{-5}, respectively. ${}^{238}UF_6$ was calculated to be more volatile than ${}^{235}UF_6$ in agreement with experiment. The feasibility of separation of uranium isotopes by exchange chromatography is discussed. (auth)

57529 LIQUID WASTES OF RADIOLOGICAL INSTITUTES AND ISOTOPE DIVISIONS. Mende, H. Sanit. Heizungstechnik: 35: No. 10, 641-7(1970). (In German).

The treatment of radioactive waste solutions of radiological institutes are described taking the "Strahlenschutzverordnung" of the Federal Republic of Germany as the basis of the considerations. Special emphasis is given to clinical laboratories and the equipment for storage and decontamination is illustrated. (INIS)

57530 ISOLATION OF BERKELIUM ON A ZIRCONIUM PHOSPHATE–SILICATE SORBENT. Myasoedov, B. F.; Barsukova, K. V.; Rodionova, G. N. (Inst. of Geochemistry and Analytical Chemistry, Moscow). Radiochem. Radioanal. Lett.; 7: No. 5-6, 269-74(10 Sep 1971).

A simple and effective method for isolation of berkelium on a zirconium phosphate–silicate sorbent in a mixture with lead dioxide was proposed, which ensures the quantitative and selective isolation of berkelium from solutions of complex composition containing other transplutonium and fission elements. The method consists in the successive passing of a 1M nitrate solution containing berkelium through two columns. On the first column filled with a pure zirconium phosphate–silicate sorbent Pu^{4+}, Cs, Nb, Zr, and partly Ru are separated. Then the solution is passed through the second column filled with a mixture of the same sorbent and PbO_2 where tetravalent berkelium is separated from macroamounts of Al, corrosion products, as well as from transplutonium and rare earth elements. The separation of Bk from Ce occurs on the lower bed of the second column, which is a mixture of anionite Dowex – 1 × 4 and PbO_2. (auth)

57531 TREATMENT OF SUSPENSIONS OR SOLUTIONS OF SOLID RADIOACTIVE MATERIAL IN LIQUID. (to Siemens Aktiengesellschaft). British Patent 1,242,665. 11 Aug 1971. Priority date 29 Jun 1968, Germany.

This method for the treatment of a suspension or solution of a solid radioactive material in a liquid involves concentrating the suspension or solution by evaporation, adding a film-forming agent to increase viscosity, and adding a binding agent. The suspension or solution is then dried in order to obtain a mass of solid material that is placed into a cask lined with a material that absorbs radiation. The film-forming agent is polyacrylamide and the binding agent is bone glue. The proposed method is cheaper and freer from dust than methods involving the imbedding of the radioactive waste material in bitumen or cement mixtures. (J.G.B.)

57532 CONTRIBUTION TO STUDIES ON GASEOUS RuO_4 REMOVAL BY MEANS OF FERRIC OXIDE-SILICA FILTERS. Donato, A.; Bocola, W. (CNEN, Rome). Energ. Nucl. (Milan); 18: No. 6, 353-9(Jun 1971).

The behavior of a ferric oxide–silica filter for ruthenium tetroxide removal from gases was studied. Removal occurs through RuO_4 decomposition mainly in the first layer of filtering material. At a temperature higher than 200°C, gas flowrates lower than 6 l/min and RuO_4 amounts less than 40 mg/min, the filter efficiency has been found higher than 99.9%. Filter efficiency increases with temperature increases and gas flowrate and RuO_4 amount decreases. (auth)

57533 EXTRACTION OF HAFNIUM WITH CYCLOHEXANONE SOLUTION OF THIOCYANIC ACID. Motov, D. L.; Skabichevskaya, G. I. J. Appl. Chem. USSR (Engl. Transl.); 44: No. 2, 247-51(Feb 1971).

Translated from Zh. Prikl. Khim.; 44: No. 2, 249-54(Feb 1971).

A study was made of the extraction of hafnium from sulfate solution obtained during treatment of native ore containing zirconium. The extraction of hafnium from sulfate solutions into cyclohexanone solutions of thiocyanic acid showed that two- or three-stage extraction at 1 : 1 volume ratio of the original sulfate solution containing zirconium to the cyclohexanone solution of thiocyanic acid gives a zirconium raffinate in which the admixture of hafnium to zirconium is about 0.02%, and also an extract containing 10 to 15% HfO_2 in Σ-zirconium and hafnium oxides. Conditions were found for stripping zirconium from the extract, giving a hafnium extract containing about 90% HfO_2 in $\Sigma\ HfO_2 + ZrO_2$. (auth)

57534 IRRADIATED NUCLEAR FUEL RECOVERY PROCESS. Weech, Marx Elson (to General Electric Co.). British Patent 1,240,766. 28 Jul 1971. Priority date 18 Jun 1968, United States.

A method for the recovery of irradiated nuclear fuel is presented. The irradiated fuel, which consists mainly of uranium or a uranium compound, is dissolved in an aqueous HNO_3 solution. This fuel solution is contacted with an organic solvent composed of TBP and a water-immiscible hydrocarbon solvent to extract U, Pu, and Np. The organic solution is passed countercurrent to an aqueous reflux stream containing sufficient U to maintain the organic solution at at least 90% of U saturation, while Pu, Np, and fission products are being scrubbed from the solution. The aqueous reflux stream is stripped of its U using TBP and a water-immiscible hydrocarbon solvent. An aqueous stream is then used to strip the U from the organic solution. A one-cycle multi-stage reflux column may be used for the process. (J.G.B.)

57535 BEHAVIOR OF NEPTUNIUM IN AQUEOUS SOLUTION. II. STABILITY OF PENTAVALENT NEPTUNIUM ION. Chang, Chau-ting; Liaw, Chiu-fong (National Tsing Hua Univ., Hsinchu, Taiwan). J. Inorg. Nucl. Chem.; 33: No. 8, 2717-20(Aug 1971).

The extraction behavior of Np(V) with TTA under the masking effect of EDTA was investigated. The dependence of the distribution coefficient, D, on pH at (EDTA) = 10^{-4} M and fixed (TTA) is illustrated graphically. D was found to increase with pH, attaining a maximum at pH of about 7, and then to decrease. The variation of D with respect to (HT) at pH 5.30 and (EDTA) = 10^{-4} M is also shown graphically. The slope was found to vary between +1 and +2. The slopes of the curves showing the dependence of apparent distribution coefficient on EDTA concentration at pH = 5.30 and fixed TTA varied between 0 and –1. Equilibrium constants for various reactions are tabulated. (UK)

57536 UNDERGROUND LEACHING OF URANIUM AT THE PITCH MINE. Marrs, Len F. Mining Congr. J.; 56: No. 11, 35-6; 41-3(Nov 1970).

High-grade U ore is being recovered by underground leaching. Research on raising the recovery rate for the ore with different solutions is in progress and it was found that increasing pH and bicarbonate levels and temperature increase production. The feed from the mill is processed through a clarifier and then treated in an ion-exchange column. An elution column strips out the U, which is precipitated as uranium hydroxide and dried to produce a product with 83% U_3O_8. (Metals Abstr.)

57537 DETERMINATION OF THE DISSOCIATION CONSTANTS OF THE DOUBLE COMPLEXES OF THE TYPE $MeY_2H_n^{(3-n)-}$ FORMED BETWEEN TRIVALENT LANTHANIDES AND HYDROXYETHYLENEDIAMINETETRAACETIC ACID. Merciny, E.; zur Nedden, P.; Duyckaerts, G. (Univ. Liege, Sart Tilman, Belg.). Anal. Lett.; 4: No. 1, 29-40(Jan 1971). (In French).

The complexes $MeY_2H_n^{(3-n)-}$ formed between trivalent lanthanides and HEDTA [indexed to N-(carboxymethyl)-N′-(2-hydroxyethyl)-N,N′-ethylenediglycine] are studied with the idea of determining their stability constants and their degree of protonation. The method is based on the titration curve of the chelating agent in the presence of an equimolar quantity of the complex MeY. (auth)

57538 HYDROGEN/DEUTERIUM SEPARATION FACTORS ON CATHODE AND DIFFUSION SIDES OF 25% Ag–Pd FOILS. Smith, Frank R. (Memorial Univ. of Newfoundland, St. John's); Hammerli, Martin Z. Phys. Chem. (Frankfurt); 74: No. 1-2, 75-7 (1971).

Separation factors for the separation of deuterium from hydrogen were measured for the gas evolved on the cathode side of Ag–Pd foils and for the gas produced after diffusion through the foils and subsequent combination. Mass spectrometric analysis of the gases made it possible to compare simultaneously the separation factors on both sides of the alloy foil. Unexpected time dependences were revealed. (J.G.B.)

57539 PROCESS AND APPARATUS FOR THE CONTINUOUS DISSOLVING TREATMENT OF SHEATHED NUCLEAR FUELS WITH A LIQUID. (to Saint-Gobain Techniques Nouvelles). British Patent 1,240,517. 28 Jul 1971. Priority date 24 Sep 1968, France.

A process for the continuous treatment of sheathed nuclear fuels with a liquid that will dissolve all parts of the fuel is described. The fuel elements are fed at a steady rate to several baskets, one after another, and immersed in a dissolving bath. The part of the element remaining in the first basket after the other part has been dissolved, but before all the baskets have been filled with fuel elements, is transferred to a rinsing bath, then removed. The liquid is fed to the rinsing bath at a steady rate, transferred to the dissolving bath, then drawn out at a constant rate. Preferably the level of liquid in the rinsing bath is maintained above the level of liquid in the dissolving bath. The result is that the rate of feed of the fuel elements and the rate of flow of the liquid into and out of the dissolving bath remain constant, the liquid and the elements being circulated in opposite directions. The only noncontinuous part of the process is the removal of the fuel or the sheaths, according to whether the liquid in the baths attacks the sheath or the fuel in the irradiated elements. The term "element" is intended to include both the uncut rod and sheath and also sections of cartridge filled with nuclear fuel. The invention extends to the design of various components of the continuous treatment apparatus. (J.G.B.)

57540 TREATMENT AND FINAL DISPOSAL OF RADIOACTIVE WASTE. Krause, H. (Gesellschaft fuer Kernforschung mbH, Karlsruhe, Ger.). Atomwirt., Atomtech.; 16: No. 8-9, 461-7(Aug-Sep 1971). (In German).

Experience obtained from more than one decade of collecting, treating, and final storing of radioactive waste in the FRG is summarized. The data reveal the possibility for handling all radioactive waste produced by nuclear energy installations in such a way that the remaining effluent radioactivity represents no danger to the environment. The Asse salt mine alone, with the addition of a few technical installations, will be able to store all radioactive waste produced in the FRG up to the year 2000. (tr-auth)

57541 THOREX TWO-STAGE PROCESS FOR REPROCESSING THORIUM REACTOR FUEL WITH HIGH BURNUP. Kuechler, L.; Schaefer, L.; Wojtech, B. (Farbwerke Hoechst AG, Frankfurt am Main). Kerntech. Atomprax.; 13: No. 7-8, 319-22(Jul-Aug 1971). (In German and English).

For the recovery of thorium and uranium from thorium reactor fuel the Thorex two-stage process was worked out that yields high decontamination factors and avoids precipitation. Hot-cell investigations showed that uranium can be decontaminated by a factor of 10^7 or more if a third uranium cycle, which was also worked out, is added to the Thorex two-stage process. (auth)

57542 REPROCESSING OF OXIDIC THORIUM-CONTAINING NUCLEAR FUEL PARTICLES WITH CHLORINE GAS. Knotik, K.; Bildstein, H. (Reaktorzentrum, Seibersdorf, Austria). Kerntech. Atomprax.; 13: No. 7-8, 323-9(Jul-Aug 1971). (In German and English).

Experimental studies are described on chloride extraction from coated uranium–thorium oxide particles. A description of the chlorinating apparatus and of the working method is followed by a discussion of the results (yield and enrichment factor of uranium). The reaction conditions were determined on the basis of results obtained in a preliminary thermogravimetric study of the chlorination of uranium carbide and thorium carbide particles. (auth)

57543 SEPARATION FACTORS IN A EUROPIUM CHLORIDE–SAMARIUM CHLORIDE–NEODYMIUM CHLORIDE–DI(2-ETHYLHEXYL)PHOSPHORIC ACID SYSTEM. Matsumoto, Akira; Takatsuji, Kazuhiko; Hirashima, Yoshiyuki; Shiokawa, Jiro (Osaka Univ.). Kogyo Kagaku Zasshi; 74: No. 7, 1328-31(Jul 1971). (In Japanese).

In a system of their aqueous chloride solutions and a solution of 1.0 mole/l of D2EHPA in n-heptane, the effects of three factors were studied on the distribution coefficients of the three elements and on the separation factors of europium with respect to samarium ($\beta_{Eu,Sm}$) and neodymium ($\beta_{Eu,Nd}$). The three factors were: HCl concentration (0.25, 0.50, 0.75 mole/l), total rare earth concentration (0.25, 0.50, 0.75 mole/l) and mole ratio (Eu : Sm : Nd = 1 : 5 : 100, 1 : 5 : 10, 1 : 2.5 : 10, 1 : 5 : 1, 1 : 1.25 : 1). As the distribution coefficient of Eu approximated that of Sm compared to the single component system, Eu and Sm behaved similarly in the extraction. The distribution coefficient of Nd decreased with an increase in the concentration of the two elements. The extraction of Nd was suppressed subsequently by the coexistence of the two elements. On the effects of $\beta_{Eu,Sm}$ and $\beta_{Eu,Nd}$, all the three factors were highly significant and the interaction of the factors was found in the case of $\beta_{Eu,Nd}$. These separation factors and the distribution coefficients of the three elements in the mixed system decreased with an increase in the concentration of HCl, of total rare earths, and of Eu in the mixed solution, respectively. (auth) (Japan)

57544 ACIDIC ORGANODIPHOSPHORUS EXTRACTANTS. PART V. EXTRACTION DEPENDENCY OF TRIVALENT EUROPIUM ON THE DIELECTRIC CONSTANT OF THE ORGANIC PHASE. Jamil, M.; zur Nedden, P.; Duyckaerts, G. (Univ., Liege). Anal. Lett.; 4: No. 2, 87-93(Feb 1971).

The extraction of Eu(III) was carried out from a 1 M (H,Na)ClO_4 solution into different organic solvents at constant total concentration (6.67×10^{-3} M) of the extractant, di-n-butyl ethane-(1,2)-diphosphonate (H_2B_2EDP). The distribution coefficient of Eu(III) is influenced quite appreciably by the nature of the organic solvent. The distribution coefficient can vary by a factor of 10^6 for two solvents such as chloroform and isooctane. The experimental results are compared with those previously reported that were obtained by using di-n-butyl phosphate (HDBP) for the extraction of Eu(III) into different organic solvents. If it is assumed that H_2B_2EDP remains a monomer for a total concentration of 6.67×10^{-3} M in the solvents used, then it may be concluded that the extraction of Eu(III) by the associated HDBP or the monomer H_2B_2EDP is influenced in the same manner in the solvents used. (auth)

57545 METHOD AND APPARATUS FOR THE PURIFICATION OF HEAVY WATER. Dirian, Gregoire; Roth, Etienne (to Commissariat a l'Energie Atomique). British Patent 1,247,590. 22 Sep 1971. Priority date 21 Jun 1968, France.

The proportion of hydrogen and tritium contained in a continuous stream of heavy water withdrawn from a nuclear reactor is lowered by an isotopic exchange reaction with deuterium gas. The heavy water is returned to the reactor and the deuterium gas thus enriched in hydrogen and tritium is subjected to fractionation by chromatography. The apparatus is shown in diagrams. (M.C.G.)

57546 EXTRACTION OF PROTACTINIUM AND ITS ANALOGS FROM SOLUTIONS OF OXALIC AND TARTARIC ACIDS WITH TRIBUTYLAMINE. Pal'shin, E. S.; Ivanova, L. A.; Davydov, A. V. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 43-7(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 48-52(Jan-Feb 1971).

The extraction of protactinium and its analogs from solutions of oxalic and tartaric acids by tributylamine in chloroform was studied. Protactinium and its analogs, Nb, Ta, Zr, are quantitatively extracted by a 0.22 M solution of TBA in chloroform from 0.1 to 0.5 M solutions of $H_2C_2O_4$. The extraction of the elements from tartaric acid solutions is less effective. The distribution of oxalic, tartaric, and phosphoric acids between the aqueous solution and TBA in chloroform was investigated. Tartaric and phosphoric acids are practically not extracted by the amine. This indicates the possibility of the use of extraction from solutions of oxalic acid with tributylamine for separation of the elements from phosphate and tartrate anions. (auth)

57547 INVESTIGATION OF PROCESSES OF OXIDATION AND DISSOLUTION OF URANIUM COMPOUNDS IN NONAQUEOUS MEDIA. I. DISSOLUTION OF URANIUM OXIDES IN SOLUTIONS OF EXTRACTION REAGENTS SATURATED WITH MINERAL

ACIDS. Filippov, A. P.; Strelkov, L. A. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 48-52(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 52-7(Jan-Feb 1971).

The possibility of selective dissolution of sparingly soluble compounds of uranium by various classes of extraction reagents in conjunction with oxidation processes, shown in this work, demonstrates a new application of extraction reagents for the direct extraction of uranium from various materials without their preliminary dissolution in acid. (auth)

57548 INVESTIGATION OF PROCESSES OF OXIDATION AND DISSOLUTION OF URANIUM COMPOUNDS IN NONAQUEOUS MEDIA. II. INFLUENCE OF THE FORM OF EXISTENCE OF NITRIC ACID IN THE TBP–HNO_3 SYSTEM ON THE PROCESS OF OXIDATION AND DISSOLUTION OF UO_2. Strelkov, L. A.; Filippov, A. P. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 53-7(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 58-62(Jan-Feb 1971).

The effective process of oxidation and dissolution of UO_2 proceeds in a TBP solution saturated with nitric acid at an equilibrium concentration of HNO_3 in the aqueous phase greater than 4M (the mole ratio $[HNO_3]_0/TBP > 0.6$). The oxidizer of U(IV) in TBP solutions is molecular nitric acid, contained in the complex TBP · $2HNO_3$ with lower stability constant. The oxides of nitrogen liberated in the oxidation of uranium are capable of repeatedly participating in the processes of oxidation and dissolution, as a result of which the degree of utilization of nitric acid in the process increases. (auth)

57549 INVESTIGATION OF COMPLEX FORMATION WITH DIETHYLENETRIAMINEPENTAACETIC ACID. I. PRASEODYMIUM(III). Piskunov, E. M.; Rykov, A. G. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 78-83(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 84-9(Jan-Feb 1971).

In separation studies it was established by pH-potentiometric and spectrophotometric methods that at an equimolar ratio of the concentrations of DTPA and praseodymium(III) in the region of pH from 1.0 to 3.6, only one complex is formed with the composition PrA^{2-} (20°, $\mu = 0.5$). Good agreement of the stability constants of the complex PrA^{2-}, determined by two independent methods, was obtained. (auth)

57550 SEPARATION OF THE ACTINIDES AND LANTHANIDES ON ZIRCONIUM PHOSPHATE. I. SEPARATION OF NEPTUNIUM(V), PLUTONIUM(IV), AND PROMETHIUM(III). Shafiev, A. I.; Efremov, Yu. V.; Nikolaev, V. M.; Yakovlev, G. N. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 120-2 (Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 126-9(Jan-Feb 1971).

The possibility of the chromatographic separation of Np(V)–Pu(IV)–Pm(III) on zirconium phosphate was demonstrated. In this case Np(V) is not retained by the ion exchanger, while the trivalent elements are eluted with 1 N HNO_3. Plutonium(IV) is eluted by rapid-action reducing agents in 0.5 to 1N HNO_3, such as 0.1N solutions of Mohr's salt, iron sulfamate, or hydroquinone. (auth)

57551 SEPARATION OF THE ACTINIDES AND LANTHANIDES ON ZIRCONIUM PHOSPHATE. II. SEPARATION OF AMERICIUM(V), (VI), AND CURIUM(III). Shafiev, A. I.; Efremov, Yu. V.; Nikolaev, V. M.; Yakovlev, G. N. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 123-5(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 129-31(Jan-Feb 1971).

Am(V) is not sorbed by zirconium phosphate and is entirely eluted by the "blank" solution. Am(VI) is retained more firmly by zirconium phosphate and is eluted with a solution of 0.05 to 0.15N HNO_3. Cm(III) behaved in exactly the same way as Pm(III), i.e., it is eluted together with Pm(III) by a solution of 1 N HNO_3. The results on the separation of a mixture of americium and curium with promethium are presented. The experiments show that zirconium phosphate is stable in oxidizing media and has no reducing effect on Am(V) and Am(VI), and it can be used to separate americium from curium and the trivalent lanthanides. (auth)

57552 SEPARATION OF RUTHENIUM, RHODIUM, AND PALLADIUM BY COPRECIPITATION WITH FERRIC HYDROXIDE. Novikov, A. I.; Rustamov, S. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 130-2(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 134-7(Jan-Feb 1971).

The coprecipitation of small quantities of ruthenium, rhodium, and palladium with ferric hydroxide in 1M solutions of ammonium nitrate and chloride was studied as a function of the pH of the medium. There was no coprecipitation of palladium under the indicated conditions; ruthenium was entirely sorbed in the interval of pH = 7 to 8 and not coprecipitated at a KOH or NaOH concentration more than 3M; rhodium was entirely coprecipitated in the interval of pH from 7 up to 3M KOH or NaOH. The elements are separated by successive coprecipitation of ruthenium and rhodium with ferric hydroxide in solution of ammonium salts at pH = 7 to 8, and in this case palladium is not sorbed by the precipitate of the carrier. Rhodium is separated from ruthenium by secondary coprecipitation with ferric hydroxide in a 3M solution of alkali in the presence of ammonia. Rhodium is separated from the carrier by reprecipitation of the ferric hydroxide at pH = 3 to 3.7 in a solution of 1M ammonium chloride and 0.2M hydrogen peroxide. (auth)

57553 SEPARATION OF THE ACTINIDE ELEMENTS AND THEIR VALENCE FORMS BY PARTITION PAPER CHROMATOGRAPHY AND THIN-LAYER CHROMATOGRAPHY. Korotkin, Yu. S. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 133-6(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 137-40(Jan-Feb 1971).

The possibility of the separation of a mixture of certain actinide elements and their valence forms in HNO_3 and $HClO_4$ by the method of partition chromatography on paper impregnated with tetrabutylhypophosphoric acid as demonstrated. Milligram quantities of U, Np, Pu, as well as Am were separated by thin-layer chromatography on Teflon-40. (auth)

57554 SEPARATION OF PLATINUM FROM THE DAUGHTER ISOTOPE OF GOLD. ISOLATION OF PLATINUM IN RADIOCHEMICALLY PURE FORM. Rakovskii, E. E.; Rabinovich, B. S.; Starozhitskaya, M. I. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 144-6(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 146-8(Jan-Feb 1971).

The possibility of producing platinum in radiochemically pure form, using extraction of the tetrachloroaurate ion with triphenylguanidinium chloride for the separation of gold, was investigated. (M.C.G.)

57555 ION EXCHANGE FIBERS AND FABRICS. II. ANION EXCHANGE FIBERS AND FABRICS STABLE IN AGGRESSIVE MEDIA. Laskorin, B. N.; Smirnova, N. M.; Yuzhina, A. D.; Semenova, E. I.; Savel'eva, T. I. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 161-4(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 160-2(Jan-Feb 1971).

The possibility of producing anion exchangers of the ÉDÉ-10P type on the basis of fluoropolymers, in the form of a powder or fabric, and polyethylenepolyamines was investigated. The optimum conditions of synthesis were determined. The synthesized anion exchangers AF-1, AF-2, and AF-3 contain 11.0, 2.6, and 6.2% nitrogen and have a total exchange capacity of 3.8, 1.05, and 4.2 meq/g, respectively. The anion exchangers sorb uranium from artificial sulfuric acid solutions (C_{eq} = 1 g/liter) in amounts of 100 to 110, 27.0, and 61.0 mg/liter for the exchangers AF-1, AF-2, and AF-3, respectively. When the uranium concentration in solution is increased to 19 g/liter, the capacity of the anion exchangers increases, reaching 170 mg/g for AF-3 fabric. The anion exchange fabrics obtained can be used to sorb the anions of acids and various metals in anionic form from solutions. (auth)

57556 DEACTIVATION OF RADIOACTIVE SEWAGE BY THE METHOD OF TWO-STEP COAGULATION OF FERRIC HYDROXIDE. Zolotavin, V. L.; Konstantinovich, A. A.; Sanatina, V. N.; Pushkarev, V. V.; Petrov, V. S. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 167-9(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 164-6(Jan-Feb 1971).

Use of a two-step process of coagulation, in comparison with one-step coagulation with the same consumption of iron sulfate, increases the degree of deactivation of radioactive sewage with respect to α activity by 12 to 20-fold, and the β activity by 2 to 5-fold. (auth)

57557 ON THE ARTICLES, STUDY OF THE RATE OF EXTRACTION IN SYSTEMS WITH TRIBUTYL PHOSPHATE, BY M. F. PUSHLENKOV AND N. N. SHCHEPETIL'NIKOV. Fomin, V. V. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 170-1(Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 167-8(Jan-Feb 1971).

57558 RAPID SEPARATION OF FISSION-PRODUCT RARE EARTHS AND YTTRIUM BY ELECTROMIGRATION. Ohyoshi, Emiko (Kumamoto Univ., Japan); Ohyoshi, Akira; Tamai, Tadaharu; Shinagawa, Mutsuaki. J. Nucl. Sci. Technol. (Tokyo); 8: No. 8, 444-9(Aug 1971).

The separation of fission-product La, Ce, Pr, Nd, and Y was performed in 4 min by electromigration. As complexing agent, nitrilotriacetic acid was used at two concentrations of the NTA ion selected so as to optimize mutual separation of the elements. Rapid location of the zone on the paper strip reached after migration was obtained by color reaction of the carrier added to the irradiated sample. The purity of the elements thus separated was checked by γ spectrometry. At the higher concentration of NTA ([NTA] = $1.0 \times 10^{-2}_{M}$, pH = 4.1) under which all of rare earths and Y migrate toward the anode, the elements were well separated from each other, although appreciable amounts of other F.P. were also found in each fraction. On the other hand, at the lower NTA concentration ([NTA] = $4.0 \times 10^{-3}_{M}$, pH = 2.0) where the F.P. all migrate toward the cathode, each zone contained the isotopes of the respective element almost exclusively, except for a few small photopeaks attributable to other elements. In each fraction, the 92.5-min ^{142}La and 14-min ^{143}La, the 14-min ^{146}Ce (24-min ^{146}Pr), the 24-min ^{146}Pr and 12-min ^{147}Pr, the 1.8-hr ^{149}Nd, the 20.3-min ^{94}Y and 10.9-min ^{95}Y were identified from the energies of photopeaks and their decay rates. (auth)

57559 POSSIBILITIES OF RAPID SEPARATION OF RADIOIODIDE, RADIOIODATE, AND RADIOPERIODATE. Palagyi, S.; Zaduban, M. (Prirodovedecka Fakulta UPJS, Kosice, Czech.). Radioisotopy; 11: No. 5, 835-49(1970). (In Czech).

Possibilities of the rapid separation of radioiodide, radioiodate, and radioperiodate based on paper, ion-exchange, and thin-layer chromatography and electrophoresis are described. Attention was paid mainly to the separation of individual chemical forms of a carrier-free radioiodine and radioiodine with a carrier on the untreated and chemically treated paper and on the thin-layer. The preparation of the carrier-free $^{131}IO_3^-$ and $^{131}IO_4^-$ by the oxidation of $^{131}I^-$ is also described. Possibilities of the application of the separation methods presented even to other radioisotopes of iodine, such as ^{132}I, ^{133}I, ^{134}I, and ^{135}I, are discussed. (auth)

57560 (INP–732) PULSED NEUTRON METHOD FOR URANIUM WELL LOGGING. Czubek, Jan A. (Institute of Nuclear Physics, Krakow (Poland)). Apr 1971. 53p. (CONF-710402–3). Dep. NTIS (U. S. Sales Only).

From Meeting on neutron sources and applications; Augusta, Ga. (18 Apr 1971).

The physical principles of a new method of uranium detection based on use of a pulsed source of neutrons are presented. The method is based on measurement of the neutron time distributions in rock media following a burst of fast neutrons. A time and energy, space independent theory is developed for the four principal time distributions occurring after production of fission neutrons by each of the two possible reactions: prompt thermal fission of ^{235}U with epithermal neutron time distribution or thermal neutron time distribution; and delayed fission of uranium with neutron time distribution due to delayed fission in ^{235}U or neutron time distribution due to delayed fast fission in ^{238}U. Theoretical analysis of these phenomena leads to the conclusion that the detection of uranium in rocks is possible using either the epithermal neutron time distribution from the prompt fission of ^{235}U by thermal neutrons or the delayed neutron distribution from fast neutron fission of ^{238}U or thermal neutron fission of ^{235}U. Experiments performed in laboratory models of uranium show the feasibility of detection of fission neutrons and the validity of the theory presented. For normal borehole logging measurements, a pulsed neutron source with an average output of about 10^9 n/sec is needed. (auth)

57561 (TID–25786) RELATIONS AMONG RADIONUCLIDE CONTENT AND PHYSICAL, CHEMICAL, AND MINERAL CHARACTERISTICS OF COLUMBIA RIVER SEDIMENTS. Glenn, J. L. (Geological Survey, Portland, Oreg. Water Resources Div.). 1971. 125p. Dep. NTIS.

Contains section on Sand Mineralogy by R. O. Van Atta.

The radionuclides discussed were produced by neutron activation of elements in Columbia River water that was used to cool the once-through nuclear reactors in the Hanford area near Pasco, Wash., prior to their final shutdown early in 1971. After return of the low-level radioactive cooling waters to the Columbia River, some radionuclides were attached to sediment particles and some particles incorporated in the streambed. Data are presented on radionuclides in size separates of streambed sediments and relations among radionuclide content, particle size, cation exchange capacity, carbon and nitrogen content, and mineralogy are described. Differences in radionuclide concentrations with particle size and with sample location are evaluated in the framework of simple models for the origin of radionuclides in streambed sediments. Chromium-51, zinc-65, scandium-46, manganese-54, and cobalt-60, in decreasing order of concentration, are the gamma-emitting radionuclides identified in Columbia River size separates. Clay separates contain an average of 36 percent of the sum of the zinc-65 concentrations in all separates; fine and medium sand separates combined contain less than 2 percent of the sum of the zinc-65 concentrations in all separates. Weighting radionuclide concentrations with results from particle-size analyses shows that the relatively more abundant fine and medium sands contain nearly 45 percent of the total amount of zinc-65; the relatively less abundant clay separate contains only 16 percent. (L.C.L.)

57562 (USGS–474–110) LOG OF HYDROLOGIC TEST WELL 1, TATUM DOME AREA, LAMAR COUNTY, MISSISSIPPI. Dribble-6. Armstrong, Clarence A.; Harris, Hobart B.; Taylor, Richard E.; Chafin, Robert V.; Shows, Thad N. (Geological Survey, Denver, Colo.). 1971. Contract AT(29-2)-474. 24p. Dep. NTIS.

Hydrologic Test Well 1 is located about 0.5 mi northeast of Tatum salt dome, Miss., the site of the Dribble Project. The well was drilled to a depth of 2,616 ft. Gamma ray-neutron, electric, micro, and sonic logs and drill core data were obtained to determine the depth, thickness, general characteristics, and stratigraphic sequence of geologic formations and aquifiers. Tabulated data is presented on aquifier zones, lithographic log of the test well, description of rotary cores, and chemical contents of test well water. (L.C.L.)

57563 (USGS–474–111) LOG OF HYDROLOGIC TEST WELL 2, TATUM DOME AREA, LAMAR COUNTY, MISSISSIPPI. Dribble-7. Armstrong, Clarence A.; Harris, Hobart B.; Taylor, Richard E.; Chafin, Robert V.; Shows, Thad N. (Geological Survey, Denver, Colo.). 1971. Contract AT(29-2)-474. 23p. Dep. NTIS.

Hydrologic Test Well 2 is located about 0.6 mi southwest of the Tatum salt dome in Mississippi, site of the Dribble Project. The well was drilled to a depth of 2,622 ft. Gamma ray-neutron, electric, micro, and sonic logs and core data were obtained to determine the depth, altitude, thickness, and areal extent of the water-bearing strata and their stratigraphic sequence; the hydrologic characteristics, such as storage and transmissibility coefficients, of the aquifers and their relationship to the geologic conditions; the hydrostatic head and the head fluctuations that occur in the observation wells completed in the hydrologic test well; the chemical and radiochemical character of the water in the aquifers; the ion-exchange capacity of the different strata as determined from selected cores; and the effects of large detonations on aquifers. Tabulated data are presented on aquifer zones, lithographic log of the test well, description of rotary cores, and chemical contents of test well water. (L.C.L.)

57564 POLLUTION OF THE ATMOSPHERE IN URANIUM MINES. Billard, F. (CEA, Fontenay-aux-Roses, France); Madelaine, G. J.; Chapuis, A.; Fontan, J.; Lopez, A. Radioprotection; 6: No. 1, 45-61(1971). (In French).

Free ions are defined and the techniques used to determine the concentration and dimension of particles suspended in the atmosphere of French uranium mines are reviewed. Measurement by counting condensation nuclei shows that the mean concentration of particles present in the air of the mine is about 5×10^4 particles/cm^3, their average diameter being around 0.1 to 0.2 μm. The charged particle mobility spectrum shows that 60 percent of the RaA, B, and C is fixed on particles smaller than about 0.1 μm and that less than 1% is fixed on free ions. The results are discussed. (auth) (France)

57565 IVORY COAST MICROTEKTITES: FISSION TRACK AGE AND GEOMAGNETIC REVERSALS. Durrani, S. A.; Khan, H. A. (Univ. of Birmingham, Eng.). Nature (London); 232: No. 5309, 320-2(30 Jul 1971).

In the studies described the minimum track inclination with the surface that leads to successful etching (known as the critical angle) was determined using a novel comparison method. A ^{252}Cf spontaneous fission source was used to bombard first an indochinite and then a microtektite for equal lengths of time under identical 2π geometry. The two materials were then etched with HF under identical conditions. The critical angle for the microtektite was found to be 24°13′, in good agreement with that for the indochinite (25°21′) determined in a similar manner by comparison with a glass slide of known critical angle. The growth of observed etch pit densities with duration of etching for an irradiated microtektite, an indochinite, and a soda lime reference glass is illustrated. The mean value of the U content of the microtektites was found to be 0.43 ppM. It was found that the deduced ages of the microtektites appeared to coincide with the dates of the last two geomagnetic reversals, indicating a possible causal relationship. (UK)

57566 RADIOMETRIC SURVEY AT THE SOUTHERN FOOT OF Mt. OBORA, MIE PREFECTURE. Matsui, Hiroshi (Geological survey of Japan, Kawasaki); Mimura, Koji. Chishitsu Chosaho Geppo; 20: 579-87(Sep 1969). (In Japanese).

This survey was carried out in Nov. 1968 to survey the radiation intensity of the Miocene sediments at the southern foot of Mt. Obora, Japan. The Miocene group, lying unconformably on the Ryoke metamorphic complex (banded gneiss, gneissose granodiorite), is divided into the Nobori, Oigano, and Mitaki formations in ascending order. The Nobori formation is the basal conglomerate of this Miocene group and the radioactive anomalies were detected at its base in the adjacent area in 1967. No anomaly is recognized at the base of the Nobori formation and in the other two formations in this field. (auth)

57567 GAMMA SPECTROMETRIC MEASUREMENT OF SOIL RADIOACTIVITY. Mishra, U. C.; Sadasivan, S. (Bhabha Atomic Research Centre, Bombay). Int. J. Appl. Radiat. Isotop.; 22: 256-7(Apr 1971).

A gamma spectrometric method of estimating concentrations of terrestrial and long-lived bomb-produced gamma emitting isotopes in countryside soil samples is described. The method was used for measuring soil samples collected during 1964 to 1970 from different places in India from undisturbed plain and open areas. The dried samples were powdered and sieved through 30 to 40 mesh size and stored in leak proof containers for at least one

XUM

month to allow for equilibration of radon and thoron with their daughters. The prominent gamma energies of the isotopes analysed (^{144}Ce + ^{144}Pr, ^{125}Sb, ^{106}Ru + ^{106}Rh, ^{137}Cs + ^{137m}Ba, ^{54}Mn, ^{238}U, ^{232}Th, ^{40}K) and the details of the analyser system used are tabulated. (UK)

57568 COSMOGENIC ^{22}Na IN SURFACE WATERS OF DRY LAND. Fleishman, D. G.; Kanevskii, Yu. P. (Inst. of Evolutionary Physiology and Biochemistry, Leningrad). Dokl. Akad. Nauk SSSR; 198: No. 6, 1397-1400(21 Jun 1971). (In Russian).

Of the cosmogenic radionuclides which are being formed in the earth's atmosphere, only ^{3}H and ^{22}Na are suitable for investigating hydrologic processes in nature. Rainfall and evaporation combined lead to an increase of ^{22}Na in surface waters as compared with that in atmospheric moisture. Rivers, as opposed to landlocked lakes, are discussed as regards the ^{22}Na content, and how the latter has been affected by the 1961 to 1962 nuclear explosions in the atmosphere. (K.S.W.)

57569 FISSION TRACK AGES AND URANIUM CONTENTS OF OBSIDIANS. Suzuki, Masao (Tokyo Univ.). Jinruigaku Zasshi; 78: No. 1, 50-8(Mar 1970).

The method of dating and measuring uranium concentrations by fission tracks is described and applied to a number of obsidians from known volcanic sources. Measured values of fission track ages and uranium contents of obsidians are given as a basis of the identification of geologic origins of obsidian artifacts from archaeological contexts. The usefulness of the method for this purpose is discussed. (auth) (Japan)

57570 MEASUREMENT OF URANIUM, THORIUM IN MANGANESE NODULES USING FISSION TRACKS AND ALPHA PARTICLE TRACKS. Yabuki, Hideo; Shima, Makoto (Inst. of Physical and Chemical Research, Yamato, Japan). Rikagaku Kenkyusho Hokoku; 47: No. 2, 27-32(Mar 1971). (In Japanese).

Induced fission track and alpha-particle track methods were used for measuring the uranium and thorium contents of four manganese nodules collected from the North and Central Pacific Ocean floor. Results for these four nodules are included in the range of 5 to 7 ppM for uranium and 18 to 32 ppM for thorium. Gamma spectrometric analysis performed for the same sample for comparison gave rather good agreement. By improving some points to cause errors, these methods could be adopted satisfactorily for determining uranium and thorium distributions in manganese nodules. (Japan)

57571 RADIOACTIVITY AND ELECTRICAL LOGGING TOOL COMBINATION. Winkler, John H. Jr. (to Schlumberger Tech. Corp.). U. S. Patent 3,566,682. 2 Mar 1971. Filed 22 Jan 1969.

An illustrative embodiment of the invention is directed to a combination sidewall radioactivity and electrical logging tool. One or more radiation detectors spaced from a source of radioactivity are housed within a skid that is urged against the borehole wall. A backup pad extending from the opposite side of the logging tool also is urged against the borehole wall. The working surface of the pad is formed of a tough electrical insulator that supports three vertically spaced electrodes. The electrodes are either flush with or recessed in the face of the insulator. This structural arrangement prevents the exposed electrodes from being short-circuited through the drilling mud or from being torn off the pad during operation. (Official Gazette)

57572 (COO–1340-24) RADIOACTIVE FALLOUT AND DISTURBANCES IN THE MID-LATITUDE WESTERLIES. Glasser, Marvin E.; Reiter, Elmar R. (Colorado State Univ., Fort Collins. Dept. of Atmospheric Science). Jul 1971. Contract AT(11-1)-1340. 37p. Dep. NTIS.

Surface radioactive fallout data for North America are compared with the meridional transport of momentum and with the shear characteristics of atmospheric flow in the lower stratosphere and upper troposphere. Cyclogenetic events during January 1964, their effect on radioactive fallout and on tropopause behavior are examined. (auth)

57573 (ORNL–4226) SIZE CLASSIFICATION OF SUBMICRON PARTICLES BY A LOW-PRESSURE CASCADE IMPACTOR. Parker, G. W.; Buchholz, H. (Oak Ridge National Lab., Tenn.). Jun 1968. Contract W-7405-eng-26. 64p. Dep. NTIS.

Aerosol particles in the submicron range are expected to be released as a consequence of a more or less severe core meltdown in reactor accidents. The behavior of aerosol particles is often explainable exclusively in terms of the laws of mechanics, which invariably include particle size as one parameter. Devices to measure particle size in the submicron region are therefore required; and a simple, passive, nearly foolproof device is particularly desirable. The principle of the cascade impactor is simple. A gas which is carrying particles is accelerated through a nozzle and impinged on a plate; particles having sufficient inertia (i.e. the large particles) leave the jet stream lines and settle on the plate. Successive stages with jets of increasing velocity remove successively smaller particles. Operation at low pressure increases the mean free path of the gas molecules and the Cunningham correction (for the slip of small particles between gas molecules). A cascade impactor of reasonable jet size which will separate submicron particles may be designed using these parameters. A commercially available (Andersen) impactor, modified for low pressure operation, and an impactor of original design were built, tested and calibrated. Design data and calibration curves are reported. The particle size range separated is from about 0.01 μ to several microns diameter. The original design impactor is assembled and disassembled very simply and employs throw-away impactor plates to facilitate decontamination. (auth)

57574 (PNE–524) OFF-SITE SURVEILLANCE FOR PROJECT SCHOONER, DECEMBER 8, 1968. Final Report. (Western Environmental Research Lab., Las Vegas, Nev.). Jun 1971. 91p. Dep. NTIS.

Project Schooner was a nuclear excavation experiment conducted at the Nevada Test Site on December 8, 1968, as part of the Plowshare Program. The results of the off-site radiological surveillance program performed for this event are presented. Aircraft observations soon after detonation indicated the top of the radioactive debris rose to approximately 19,000 feet above mean sea level. Aircraft and ground monitoring showed that the main cloud moved to the northeast across Utah and Colorado, while the base surge moved north into Idaho and then eastward across Montana and North Dakota. The highest external gamma exposure rate observed off-site was 350 mR/hr at 1100 hours PST on an azimuth of 54 degrees and at a distance of 44 miles from ground zero. The highest external gamma exposure rate observed at a populated location was 8.5 mR/hr at the Diablo Maintenance Station (33°, 47 miles) on Highway 25. The highest integrated external gamma exposure to an off-site resident wearing a personal dosimeter was 165 mR, received by a sheepherder from Uhalde's Ranch near Adaven, Nevada (45°, 75 miles), from December 8 through 17, 1968, while he was working several miles east of the ranch. The predominant radionuclide found in environmental samples was ^{187}W. The highest integrated ^{187}W concentration observed in air at a populated location was 12,000 μCi · sec/m^3 at Stickelman's Farm (357°, 55 miles) near Clark Station on December 8, 1968. The highest ^{187}W concentration in milk (9,100 pCi/l) was found in a December 9, 1968, sample from the Chavis Ranch (57°, 127 miles), north of Pioche, Nevada. The highest ^{187}W concentration (21,000 pCi/l) in a water supply used for human consumption was found in a December 11, 1968, sample from the Simpson's Ranch (42°, 75 miles) at Adaven, Nevada. The highest ^{3}H concentration in a water supply used for human consumption (2,800 pCi/l) was found in a December 11, 1968, sample from the Lotspeich Ranch (15°, 266 miles) near Deeth, Nevada. Iodine-131 was found in its highest concentration in milk (100 pCi/l) in a December 11, 1968, sample from the Boyd Schena Ranch (56°, 252 miles) near Abraham, Utah. The only other isotope of interest, ^{181}W, has been found in low levels in natural vegetation which has grown since the occurrence of the Schooner deposition, and in the muscles of cattle grazing in the deposition areas. Analyses of radiological data indicate that radioactive effluent arising from this event did not present any health hazard to the off-site population, based on presently accepted safety criteria established by the USAEC. (auth)

57575 (RA–42) GROSS RADIOACTIVITY IN AIRBORNE DUST. RESULTS OF MEASUREMENTS DURING 1967. van Dongen, R.; Moonen, H. P. M.; Wolf, H. J. (Rijks Instituut voor de Volksgezondheid, Bilthoven (Netherlands). Laboratorium voor Stralingsonderzoek). Apr 1968. 12p. Dep. NTIS (U. S. Sales Only).

Gross long-lived alpha, beta, and gamma activities of airborne dusts collected at De Bilt/Bilthoven, the Netherlands, during 1967, are reported. A short discussion of some results is given. (auth)

57576 RADIOAKTIVNOST' ATMOSFERY. Doklady na Simpoziume v g. Obinske 30 Iyulya–2 Avgusta 1868 g. (Radioactivity of the Atmosphere. Symposium Held at Obninsk, 30 July–2 August, 1968). Makhon'ko, K. P. (ed.). Trudy Inst. of Experimental Meteorology, No. 17. Moscow; Moskovskoe Otdelenie Gidrometeonzdata (1970). 132p. (CONF–680733).

Information on the products of nuclear explosions residing in the atmosphere and those that comprise eventual fallout on the ground is included. Radioactive fallout in the USSR during the interval 1963 to 1967, and airborne radioactivity in Prague are also discussed. Three papers were presented which deal with the natural radioactivity of the atmosphere in Budapest, Bratislaw, and throughout the USSR. The use of radioactive tracers to investigate mixing of air in the stratosphere and troposphere is also discussed. The last five papers consider methodology: sampling and measurement of aerosols; types of filters; and filter correction factors. (K.S.W.)

57577 RADIOACTIVE PARTICLES FROM THE EIGHTH CHINESE NUCLEAR TEST. **Persson, Gunnar; Sisefsky, Jan (Research Inst. of Swedish National Defence, Stockholm). Health Phys.: 21: No. 3, 421-8(Sep 1971).**

Debris from China's eighth nuclear explosion test was examined with γ spectrographic and autoradiographic methods. Nearly all of the debris was borne by submicroscopic particles, and "hot" particles, visible under the microscope (≥ 0.2 μm) were very rare. The few found were all nearly colourless spheres. Their specific β activity was the highest found so far. The largest particles are highly fractionated (especially mass-chain 141) but debris "in bulk" is not, as the gravitational separation between differently sized particles during the transport process is negligible. The difficulties in interpreting the fractionation factors of the hot particles as a reflection of the time between explosion and particle formation are discussed. If the particles are assumed to consist of Al_2O_3 and no mutual fractionation between Al and mass-chain 95 has occurred, the content of inactive construction material incorporated in the fire ball is estimated to be ~300 kg Al. (auth)

57578 RADIOACTIVE CERIUM FALLOUT AND HOT PARTICLES IN THE ATMOSPHERE. **Beck, James Noble. Fayetteville, Ark.; Univ. of Arkansas (1971). 89p. University Microfilms Order No. 71-19,534.**

Thesis

A study of the variation of the radioactive cerium isotopes in rain at Fayetteville, Arkansas, was carried out during the period between May 1, 1966, to December 31, 1968. The mean stratospheric residence time for ^{144}Ce was calculated and a value of 0.84 year was obtained for data collected in this laboratory since 1963. A fine structure was observed in the variation of the ^{141}Ce/^{144}Ce immediately after the third Chinese nuclear explosion of June 9, 1966, and the seventh Chinese nuclear explosion of December 24, 1967. This fine structure was explained as being due to the fact that the debris travels rapidly eastward and circles the earth a number of times. Long-range 500 mb and 300 mb air trajectories were computed in an attempt to interpret the daily variation of the number of fallout particles in the ground-level air observed at Fayetteville (36°N, 94°W), Arkansas, after a nuclear weapon was tested at Lop Nor (40°N, 90°E), China, on December 24, 1967. The dates of occurrence of peak concentrations of fallout particles generally coincided with the arrival times of air masses at 500 mg and/or 300 mb after completing a cycle around the world and the passage of 500 mb troughs at Fayetteville. (auth)

57579 RECENT FALLOUT OF RADIOACTIVE DUST IN JAPAN. **Miyake, Y. (Tokyo Univ. of Education); Katsuragi, Y. Tenki (Meteorol. Soc. Jap.): 17: No. 12, 593-8(Dec 1970). (In Japanese).**

The change of ^{137}Cs and ^{90}Sr fallout at eight localities in Japan from 1963 to a recent date was investigated. Recent nuclear weapon experiments by Communist China have been affecting the ^{90}Sr fallout in whole northern hemisphere, and their effects were estimated. The residence time of ^{90}Sr in the stratosphere, estimated from the amount of ^{90}Sr fallout from 1963 to 1966, is 1.3 to 1.4 years. Relations of the ^{90}Sr fallout in each locality in Japan with the amount of ^{90}Sr in the stratosphere over the northern hemisphere and with the ^{90}Sr fallout in the whole northern hemisphere are also discussed. The amounts of ^{90}Sr in the stratosphere over the northern hemisphere at the ends of 1967 and 1968 were 250 kCi and 200 kCi, respectively. The ^{90}Sr fallout in 1969 estimated from these values, is about 80 percent of that in the preceding year, and this coincides with the value 0.84 estimated from the ^{90}Sr fallout in the six localities in Japan. (Japan)

57580 DEBRIS OVER SWEDEN FROM THE CHINESE NUCLEAR WEAPON TEST SEPTEMBER 1969. **Sisefsky, J.; Persson, G. (Research Inst. of Swedish National Defense, Stockholm). Health Phys.: 21: No. 3, 463(Sep 1971).**

Debris from China's 10th nuclear test was air-sampled at 14 km over Sweden, and found to be very similar to that from China 8. Maximum debris (number of fissions per kg air) was found six months after the explosion and measurements are continuing. Debris was examined γ spectrographically and the $(n,\gamma)/(n,2n)$ ratio found to be 1.4; characteristic of a thermonuclear device. (UK)

57581 ANALYSIS OF PROCESSES OF URANIUM REDISTRIBUTION AND DETACHMENT FROM ROCKS DURING THEIR PROGRESSIVE METAMORPHISM. **Ermolaev, N. P. (Inst. of Geochemistry and Analytical Chemistry, Moscow). Geokhimiya; No. 8, 949-62(Aug 1971). (In Russian).**

Redistribution and detachment of uranium dispersed in rocks occurs during progressive metamorphism and ultrametamorphism of these rocks in processes of: recrystallization of sediments; desorption of uranium by aqueous carbonate solutions, which are formed during metamorphism; and rock transformation with removal of components—carriers of uranium (divalent bases, titanium) during granitization of sediments. Uranium removal from rocks is realized in a complex carbonate form or (under non-carbonate conditions) in association with the hydrometasilicate ion. (auth)

57582 ENHANCING BACTERIAL ACTIVITY IN A URANIUM MINE. **Duncan, D. W.; Bruynesteyn, A. (British Columbia Research, Vancouver). CIM (Can. Mining Met.) Bull.; 64: 32-6(May 1971).**

Acidic mine waters containing solubilized uranium were observed in many uranium and some copper mines. In every case, the sulfide and iron oxidizing bacterium, Thiobacillus ferrooxidans, was also present. This bacterium provides the ferric iron required to oxidize U^{+4}, both by oxidizing available ferrous iron and by oxidizing pyrite or other available sulfide minerals. This latter oxidation also provides sulfuric acid and may increase extraction by exposing more uranium. The enhancement of bacterial activity and the results of some field tests are discussed. (auth) (Canada)

57583 URAN V GRANITOIDAKH RAIONA GUL'SHAD TSENTRAL'NYI KAZAKHSTAN. **(Uranium in Granite in the Gul'shad Region, Central Kazakhstan). Ivanov, D. N. Leningrad; Izdatel'stvo Nauka Leningradskoe Otdelenie (1967). 80p.**

Elementary statistical methods were used to investigate the distribution of uranium in various types of granites from central Kazakhstan, USSR. This work showed the specific nature of U distribution in granites and explained how mathematical methods can be used to solve geochemical problems. The systematic study of granites showed that U is accumulated in acid intrusions and parallels the accumulation of potash and silicon. (tr-auth)

57584 SEDIMENTARY URANIUM DEPOSITS. **Robertson, David S.; Doublas, Richard F. (David S. Robertson and Associates, Ltd., Toronto). CIM (Can. Mining Met.) Bull.; 63: No. 697, 557-66(May 1970).**

Proterozoic quartz-pebble conglomerates contain about 60% of the known uranium reserves. These are all similar in appearance, in mode of distribution and in manner of origin. They carry uranium minerals and/or gold and abundant pyrite. Their unique distribution in Huronian time required a pre-existing crust well enough evolved to have plentiful quartz and abundant gold, uranium and pyrite. The materials of value were deposited as detrital heavy minerals prior to the appearance of an oxidizing atmosphere in late Proterozoic time. Epigenetic uranium deposits occur in arkosic sedimentary rocks through the entire geological column. About 30% of the western world's known ore reserves are in these rocks. This type of deposit is particularly prominent in semi-arid parts of the United States, having yielded most of the uranium ore produced and containing nearly all of the known reserves. The Western States type of deposits occur in lenticular, permeable stream-laid sedimentary rocks. The deposits are believed to have been precipitated from moving ground water at locations where plant debris or other organic matter had accumulated. The uranium may be derived from volcanic sediments, which are commonly associated with the units containing the ore, or it may be leached from exposed granite surfaces or from granitic debris which forms the sediments. A significant part of the world's uranium resources are in black shales and lignitic rocks. The lignites that contain uranium are virtually valueless as potential sources of heat. Uranium concentrations at levels such as to be potential sources of by-product uranium occur in many phosphorites. Reworked sediments may provide uranium in pegmatites and vein-like deposits. (auth) (Canada)

57585 ANOMALOUS ^{234}U/^{238}U ON THE EAST PACIFIC RISE. **Veeh, H. Herbert (Australian National Univ., Canberra); Bostroem, Kurt. Earth Planet. Sci. Lett.; 10: 372-4(Feb 1971).**

Data on the isotopic composition of uranium and thorium in sediments and iron deposits from the East Pacific Rise are reported and are used to support theories as to the origin of uranium in these iron-rich sediments. (L.C.L.)

57586 CONSTANT GEOMETRY APPROACH TO IN SITU SEABED GAMMA MONITORING. Reynolds, E. (Fisheries Radiobiological Lab., Lowestoft, Eng.). Health Phys.; 20: 241-51 (Mar 1971).

An in situ, temperature compensated, seabed gamma probe is described and the application and design philosophy discussed. Experimental results obtained in the Irish Sea are compared with results from seabed samples analyzed in the laboratory. The agreement between the two sets of data indicates the usefulness of the method for the rapid assessment of the intensity of the seabed gamma field arising from radioactive waste disposal. (auth)

57587 URANIUM GEOCHEMISTRY OF THE GULF OF MEXICO. Sackett, W. M.; Cook, G. (Texas A and M Univ., College Station). Trans., Gulf Coast Ass. Geol. Soc.; 19: 233-8(1969). (ORO-3852-2).

The economic importance, the dissimilarity in chemical behavior of its two oxidation states and the unique usefulness of its radioactive daughter products make uranium and its geochemistry extremely interesting to earth scientists. The Gulf of Mexico (GOM) has the attractive feature of being a semi-closed system that offers the possibility of a complete monitoring of all inputs and removal processes for trace elements such as uranium. Experimental values obtained in this study of the geochemical cycle of uranium in the GOM are given. High uranium concentrations in midwest U.S.A. rivers relative to other rivers of the world can be explained by solubilization of the uranium in phosphate fertilizers applied to the land surface. Estimated pre-fertilizer uranium input to the GOM is nearly balanced by uranium co-deposition with carbonates on the Yucatan shelf. (auth)

57588 QUESTION OF POSSIBLE VARIATIONS IN THE PAST CONCENTRATIONS OF URANIUM IN THE OCEAN. Kuznetsov, Yu. V. Sov. Radiochem. (Engl. Transl.); 13: No. 1, 113-19 (Jan-Feb 1971).

Translated from Radiokhimiya; 13: No. 1, 118-25(Jan-Feb 1971).

On the basis of experimental data on the vertical distribution of ^{230}Th and uranium in core samples of ocean sediments, the presence of an excess of ^{230}Th in the sedimentary core samples with respect to the amounts of it that should have been deposited from the column of water above the deposit was established. Working hypotheses explaining the detected phenomenon are presented. (auth)

57589 (CGS-746-12) EARTHQUAKES ON AND AROUND THE NEVADA TEST SITE, 1950-1971. King, Kenneth W.; Bayer, Kenneth C.; Brockman, Stanley R. (National Oceanic and Atmospheric Administration, Las Vegas, Nev. Earth Sciences Labs.). Aug 1971. Contract AT(29-2)-746. 32p. Dep. NTIS.

World seismic data files were searched for earthquakes that occurred within a 100 mi radius of the Nevada Test Site (NTS) during the period from 1950 to Aug. 1971. Since 1968 18 stations located near the NTS have monitored seismic activity in the area. Data showing the geographic location and magnitude of earthquakes and principal aftershocks for each year and information which relates the time of specific nuclear detonations and the date and location of earthquakes are presented. (L.C.L.)

57590 (COO-2138-4) AN INVESTIGATION INTO THE POTENTIAL SEISMOLOGICAL EFFECTS OF THE CANNIKIN EVENT. Willis, D. E.; Poetzl, K. G.; Saltzer, C. E.; Shakal, A. F.; Woodzick, T. L. (Wisconsin Univ., Milwaukee. Dept. of Geological Sciences). Sep 1971. Contract AT(11-1)-2138. 239p. Dep. NTIS.

The potential seismological effects of the proposed CANNIKIN underground nuclear shot at Amchitka are discussed. The main three areas of concern were considered to be the generation of a large natural earthquake by the shot, changing the regional seismicity pattern of naturally-occurring events, and the possible generation of a damaging tsunami. These studies indicate a very low probability that any damaging effects from the above would result from the CANNIKIN test. A statistical study of the Aleutian arc area indicates that there is a mean probability of 0.86% for a $M_s \geq 8.0$ earthquake occurring in the whole area in any given month and a 1.96% relative probability of a $M_s \geq 8.0$ earthquake occurring in the Rat Island/Amchitka area in any given year. 57591 (INIS-mf-71, pp 181-98) PROGRESS OF SEISMOLOGY IN INDIA. Tandon, A. N. (Bhabha Atomic Research Centre, Bombay (India)). 1970. (CONF-690730-1). INIS.

From Symposium on use of Gauribidanur data for seismological research; Bombay, India (4 Jul 1969).

Seismological developments in India from 1869 are traced. A description of the seismic array of the Bhabha Atomic Research Center at Gauribidanur is given. The Center has undertaken research in seismology directed primarily towards establishing more effective techniques for precisely locating underground nuclear explosions in time and space and to exploit the possibility of identifying such sources. (INIS)

57592 (JAB-99-70) APPROXIMATE PROCEDURE FOR DETERMINING BUILDING DYNAMIC RESPONSE CHARACTERISTICS. Raggett, Jon D. (Blume (John A.) and Associates Research Div., San Francisco, Calif.). Oct 1971. Contract AT(26-1)-99. 23p. Dep. NTIS.

An analytical procedure for determining the linear dynamic response characteristics of a building given a time history of the response of a point on the building and a time history of the ground motion is described. Modal characteristics are equated to those of a single-degree-of-freedom system which best fits the building response in a least squares sense. This best fit modal response is subtracted from the total response and the residual is treated in an analogous manner for the next most dominant mode. Two hypothetical and one actual building-ground time history pairs are analyzed using this procedure. Visual comparisons between actual and regenerated response time histories are made. (auth)

57593 (TID-25572) NUCLEAR-EXPLOSION SEISMOLOGY. AEC Critical Review Series. Rodean, Howard C. (California Univ., Livermore. Lawrence Livermore Lab.). 1971. 164p. Dep. NTIS.

Unclassified information that is pertinent to the generation of seismic signals by underground nuclear explosions, including the phenomena associated with decoupling and low-coupling techniques to minimize the seismic signals is summarized. These related topics are introduced with a review of the history of nuclear-explosion seismology and a general description of nuclear-explosion phenomena. The fraction of nuclear-explosion energy that is radiated in the form of seismic waves ranges from a few percent down to a few hundredths of one percent. This wide variation is a consequence of corresponding variations in the inelastic response of the material immediately surrounding the explosion. Some insight into inelastic-region phenomena is given by static-equilibrium solutions, but for an understanding of how explosions generate seismic waves, the dynamic process of inelastic-stress-wave propagation must be considered. Several theoretical and experimental examples of inelastic wave propagation, including a recent computer calculation of a 5-kt nuclear explosion in granite, are given. The physical principles of elastic-wave theory are summarized for three types of waves, P, S, and R, which are of predominant importance in differentiating between explosions and earthquakes. Other types of seismic waves are also generated by explosions and earthquakes, but this study is restricted to these three. The P or compressional waves are the first to arrive at distant seismic stations and are used in detection of seismic events. The R or Rayleigh waves, together with the P waves, are presently the most important with respect to identification of the event as an explosion or an earthquake. The S or shear waves are considered because, if R waves exist, P and S waves are also present. The discussion of P waves is more extensive than that for either S or R waves because much more theoretical and experimental information is available concerning the generation of P waves by explosions. Theoretical P-wave solutions are presented for both head and teleseismic varieties, with and without anelastic attenuation, as a function of explosion yield. Corresponding theoretical amplitude-yield curves for assumed seismometer-response functions are also presented. Available experimental amplitude-yield and magnitude-yield data for P waves are also given, and the observed effects of different geological environments, as well as cavities, on distant seismic signals are discussed. Concluding the review is a summary of what is and is not known concerning the generation of seismic waves by underground nuclear explosions. The greatest unknowns include accurate equations of state for rocks, especially for the process of adiabatic unloading, necessary for a complete description of inelastic-stress-wave propagation and the influence of various explosion parameters on R-wave characteristics. (auth)

57594 (UCRL-73369) CALCULATION OF SURFACE AND GROUND WAVES FROM ABOVE-GROUND AND UNDERGROUND EXPLOSIONS. Wilkins, Mark L. (California Univ., Livermore. Lawrence Radiation Lab.). 25 Aug 1971. 18p. (CONF-710918-1). Dep. NTIS.

From third international conference on gasdynamics of explosions and reactive systems; Marseille, France (12 Sep 1971).

The effectiveness of finite difference techniques for the study of wave and ground motions resulting from both above-ground and underground explosions is demonstrated. The accuracy of the calculational technique is established by a comparison with a selected problem that can be solved by other methods for the propagation of Rayleigh waves. Solutions are given for an explosion above the surface and for explosions below the surface. (auth)

57595 (USGS-474-112) VELOCITY CROSS SECTION 5, EXTENDING SOUTHWEST FROM TATUM DOME, LAMAR COUNTY, MISS. Eargle, D. Hoye; Black, R. A.; Davis, Beth O.; Stanford, J. F. Jr. (Geological Survey, Denver, Colo.). 1962. Contract AT(29-2)-474. 11p. Dep. NTIS.

Velocity cross section 5 extends about 18 miles southwest from Tatum salt dome, south-central Lamar County, Miss., to the northeastern part of Washington Parish, La. Cross section 5 shows major sonic velocity zones (and lateral variation of sonic velocity within these zones) for a region within a radius of about 25 miles of Tatum salt dome. Tatum dome is the site proposed for a series of seismic experiments (Dribble Project), for improving the detection of underground nuclear explosions. Data on sonic velocities of the sedimentary rocks surrounding Tatum dome are required for planning of instrumentation for recording the proposed seismic events and in the interpretation of the recorded seismograms. (auth)

57596 (USGS-474-129) STRUCTURE OF THE SOUTHEASTERN MISSISSIPPI REGION. Dribble-26. Eargle, D. Hoye; Stanford, John F. Jr.; Davis, Beth O. (Geological Survey, Denver, Colo.). 1971. Contract AT(29-2)-474. 23p. Dep. NTIS.

Logs of about 230 wells were analyzed and the data used to define the subsurface structure of the southeastern Mississippi region, an area of about 3,000 square miles in southeastern Mississippi and the northeastern part of Washington Parish, La. This subsurface structure was determined in order to characterize the lateral and vertical distribution of seismic velocities within the subsurface sedimentary rocks. The three-dimensional distribution configuration of the rocks is of interest in connection with Project Dribble at Tatum salt dome, Lamar County, Miss. Tatum salt dome is near the center and approximately 25 miles from the edges of this nearly square area. Structure-contour maps were prepared showing the tops of four lithologic units that are consistent sonic-velocity units. Isopach maps were prepared showing the thicknesses of selected stratigraphic units within the Cretaceous and Tertiary rocks. From a comparison of these maps some significant incidents in the geologic history and environmental conditions prevailing in the region can be reconstructed. (L.C.L.)

57597 EXPLOSION EFFECTS AND EARTHQUAKES IN THE AMCHITKA ISLAND REGION. Engdahl, E. R. (National Oceanic and Atmospheric Administration, Boulder, Colo.). Science; 173: No. 4003, 1232-5(24 Sep 1971).

Microearthquakes were monitored by a network of seismographs located on Amchitka and nearby islands; the nature of earthquake activity in this region was found to be consistent with the hypothesis of underthrusting of the Aleutian arc by a rigid lithospheric plate. Seismic effects of the nuclear explosion Milrow were small, of short duration, confined to the region immediate to the explosion, and were apparently independent of this geotectonic mechanism. (auth)

57598 EARTHQUAKE RESPONSE ANALYSIS OF NUCLEAR POWER PLANT. Muto, Kiyoshi; Uchida, Kazuyoshi; Inoue, Masasuke; Iwata, Yukio (Kajima Construction Co. Ltd., Tokyo). Kajima Kensetsu Gijutsu Kenkyusho Nempo; 18: 399-406(Oct 1970). (In Japanese).

Problems of damping and methods of simulating the earthquake response of BWR-type nuclear power plants are discussed. In earthquake response analysis for nuclear power plants, special attention must be paid to the simulation of the vibration model. If the structural behavior of each part of the nuclear power plant cannot be simulated correctly for earthquakes it is impossible to analyze earthquake response. As is well known in earthquake response analyses for ordinary buildings, almost any kind of conclusion may be reached at the stage of simulating the vibration model. Hence, even if calculations are made by a digital computer, the results may not always be satisfactory. Therefore, in order to obtain reliable results, it is necessary to use accurate information; that is, simulations must fit the conditions between vibration models and actual structure. By examining phenomena from both theoretical and practical aspects, it is possible to assess them more accurately, verifying information, and giving trustworthy calculation results. The dynamic system of nuclear power plants, consisting of buildings and equipment, is so complicated that it is hardly possible to work out a perfect idealization of the vibration model with current deficiencies in information. However, in view of the importance of nuclear power plants, more than cursory efforts must be made to create an accurate model. (auth) (Japan)

57599 P-WAVE SPECTRA FROM UNDERGROUND NUCLEAR EXPLOSIONS. Molnar, Peter. Geophys. J. Roy. Astron. Soc.; 23: 273-87(1971).

Observations are reported of P-wave spectra from underground nuclear explosions for periods greater than about 1 sec. The spectra have a maximum at about 2 to 3 sec and decrease rapidly at longer periods. Two phenomena could cause such a decrease: the surface reflection (pP), with its polarity opposite to that of the direct P wave, might differentiate the long-period signal and cause a modulation of $2|\sin \omega t_0/2|$ where t_0 is the interval of time between P and pP; or the source time function for the pressure on the boundary of the elastic zone surrounding the explosion might more nearly resemble an impulse than a step function as often assumed. The data are consistent with the simultaneous occurrence of both phenomena, but they are of insufficient quality or quantity to establish which is more important. If other information shows that the reflection does not have a large effect on the observed spectrum, then the data show that the source time function is primarily an impulse. In addition, the pronounced difference in spectral content of P waves from earthquakes and underground nuclear explosions suggests a method for identification that is applicable for explosions large enough to be recorded by long-period seismographs at teleseismic distances. This method may be particularly important when long-period instruments are disturbed by other events and methods of identification that rely on analysis of surface waves become inapplicable. (auth)

57600 DISCRIMINATION OF EARTHQUAKES AND EXPLOSIONS USING SHORT PERIOD SEISMIC ARRAY DATA. Anglin, F. M. (Dept. of Energy, Mines, and Resources, Ottawa). Nature (London); 233: No. 5314, 51-2(3 Sep 1971).

It is stated that, using data recorded at the Yellowknife short period seismic array in northern Canada, a simple two-divisional identification parameter was obtained that completely separated underground explosions at some Soviet test sites from shallow earthquakes within about 15° of these sites. Optimum discriminants were obtained both in the time and frequency domains. Extensive testing will be necessary to show whether this short period discriminant will apply on a worldwide basis or for larger event populations; if it does, it should provide a positive discriminant for explosions with yields <10kT in hard rock. 57601 (LMSC–D-177630(Vol.2)) STUDY OF NUCLEAR EXPLOSION SERVICES FIELDING SYSTEM. VOLUME II. SUPPORTING DATA (APPENDIXES A THROUGH H). Final Report, Phase II. (Lockheed Missiles and Space Co., Sunnyvale, Calif.). 24 Jun 1971. Contract AT(26-1)-526. 351p. Dep. NTIS.

Volume II of the final report of Phase II of the Study of Nuclear Explosion Services Fielding System is presented and consists of the following eight appendixes: user explosive emplacement schedules; NES field personnel requirements; explosive transportation requirements data; control system; NES headquarters personnel and facilities requirements; system and subsystem evaluation methodology; cost models and cost data; and reference data. (L.C.L.)

57602 (SC-RR-69-376) GROUND MOTION PREDICTIONS FOR AMCHITKA. Merritt, M. L. (Sandia Labs., Albuquerque, N. Mex.). Jul 1969. 51p. Dep. NTIS.

Predictions of ground motion and underwater pressures from nuclear shots at Amchitka were made using Long Shot data against the background of Nevada experience. The ground motion data agree very nicely with data from previous shots in hard rock, but the underwater data can only be compared with theory, and the agreement is poor. Long Shot did not form a collapse crater but the larger shots in Nevada did, so that it is probable that large shots at Amchitka will also. Thus, a megaton device buried at 4000 feet is predicted to produce a surface zero acceleration of 24 g and a permanent displacement before collapse of 1.5 feet. Vertical accelerations will be above 1 g to a range of two miles. Overpressures in water will be above 300 psi to a range of 7000 feet. (auth)

57603 (TID-3522(Rev.9)) A SELECTED, ANNOTATED BIBLIOGRAPHY OF THE CIVIL, INDUSTRIAL, AND SCIENTIFIC USES FOR NUCLEAR EXPLOSIONS. West, Robert G. (comp.) (Division of Peaceful Nuclear Explosives (AEC), Washington, D. C.); Kelly, Robert C. (comp.) (Division of Technical Information Extension (AEC), Oak Ridge, Tenn.). Sep 1971. 359p. Dep. NTIS.

This bibliography contains 1594 annotated references to reports and published literature on the USAEC's Plowshare Program. The references are arranged by subject category. Report Number and Availability, Author, Experiment, and Foreign Literature Indexes are included. (auth)

57604 (UCRL-73130) NUCLEAR CHIMNEYS: UNDERGROUND CONTAINERS FOR CHEMICAL AND METALLURGICAL PROCESSING. Lewis, A. E. (California Univ., Livermore. Lawrence Radiation Lab.). 26 Aug 1971. 32p. (CONF-711105–1). Dep. NTIS.

From Symposium on the underground environment; Washington, D. C. (3 Nov 1971).

It is practical to use contained nuclear explosions to construct underground openings (nuclear chimneys) under a variety of geologic conditions. The underground environment of these chimneys provides opportunities for the development of industrial processes that may not be practical at the earth's surface. Examples discussed are: the in situ, high-pressure, high-temperature recovery of metals from sulfide ores, and the in situ incorporation of nuclear-fuel reprocessing waste in molten silicate rock. (auth)

57605 GAS PRODUCTION BY NUCLEAR STIMULATION. Glass, Eugene D. (to Cities Service Oil Co.). U. S. Patent 3,566,966. 2 Mar 1971. Filed 26 Sep 1968.

Gases in the chimney of broken reservoir rock formed by the detonation of a nuclear device are withdrawn as quickly as possible following the detonation. The gases are pumped to another geologic horizon for disposal until the level of long half-life, gaseous contamination drops below the tolerable limits for such contamination. By withdrawing the contaminated gases from the chimney quickly, the pressure in the chimney at the time of withdrawal will be near that immediately after the nuclear explosion and will not have built up to values near the equilibrium pressure of the reservoir. The amount of reservoir gas contaminated with radioactivity and the consequent disposal problem are thereby minimized. Decontaminating processes at the surface to reduce the long half-life, gaseous contamination may be avoided. When the level of the long half-life, gaseous radioactive contamination falls below the tolerable limits for such contamination, the gases thereafter withdrawn from the chimney may be recovered as product gas suitable for processing and use. (Official Gazette)

57606 ESTIMATION OF NUCLEAR EXPLOSION ENERGIES FROM MICROBAROGRAPH RECORDS. Posey, J. W.; Pierce, A. D. (Massachusetts Inst. of Tech., Cambridge). Nature (London); 232: No. 5308, 253(23 Jul 1971).

An approximate theoretical relationship was developed between certain air waveform features from nuclear explosions and energy yield; this relationship is stated to be insensitive to changes in atmospheric conditions, such as average atmospheric temperature and wind profiles above the path connecting source to microbarograph, small changes in which appear to cause relatively large changes in the waveforms. The extent to which this relationship agrees with experimental data was examined. (UK)

57607 ANALYSIS OF JORUM CONTAINMENT. Crowley, B. K.; Glenn, H. D.; Kahn, J. S.; Thomsen, J. M. (Univ. of California, Livermore). Int. J. Rock Mech. Mining Sci.; 8: No. 2, 77-96(Mar 1971).

A pioneering calculational effort is described that dealt with problems relating to the stemming of an underground nuclear event before the event occurred. The Jorum Event presented two often-encountered situations: stemming of the main emplacement hole and stemming of a satellite hole. This event was unusual, however, in that portions of these holes were located below the water table. One- and two-dimensional, time-dependent, finite difference calculations that solved the conservation equations, with general equations-of-state and static and dynamic frictional forces, were used to simulate the two stemming situations. The models, assumptions and parameters used in the various calculations are discussed. Even when conservative parameters were used to represent the effects of water, the calculational results indicated that the planned stemming configurations would contain the event. (auth

57608 (70-CNA-658) CANADIAN CENTRIFUGAL PUMP INDUSTRY: TWENTY YEARS OF DYNAMIC GROWTH. Meschino, J. L. (Borg-Warner (Canada) Ltd., Toronto (Ontario). Byron Jackson Div.). [1970]. 13p. (CONF-700564–13). Dep. NTIS (U. S. Sales Only).

From tenth annual international conference of the Canadian Nuclear Association; Toronto, Canada (24 May 1970).

Centrifugal pump manufacturing in Canada, particularly for the nuclear industry, is reviewed. In 1950 there was no fully integrated pump industry in Canada. Heavy pump equipment for refinery and process industries had to be imported completely or parts brought in for assembly only. By 1970 Canada could produce with its own labor and materials pumps for any industry including those required by power utilities, for nuclear or conventional thermal stations, regardless of size or horsepower. Specific pumping systems which have been built or which are under construction are described. (L.C.L.)

57609 (AED-C-1-18) BIBLIOGRAPHIES IN NUCLEAR SCIENCE AND TECHNOLOGY. Section 01: Civil Engineering. (Zentralstelle fuer Atomkernenergie-Dokumentation, Frankfurt am Main (West Germany)). May 1971. 100p. (In English and German). Dep. NTIS (U. S. Sales Only).

A bibliography of 130 articles published from 1966 to 1971 on prestressed concrete pressure vessels for reactors is presented. The following indexes are included: author; report number; subject; source material, including regular publications, symposium reports, and individual reports. (L.C.L.)

57610 (BNL-50293) EXPERIMENTAL WORK IN THE BROOKHAVEN CHEMONUCLEAR IN-PILE RESEARCH LOOP. Beller, M.; Tucker, W.; Steinberg, M. (Brookhaven National Lab., Upton, N. Y.). Dec 1970. 58p. Dep. NTIS.

Chemonuclear processes making direct use of the energy of the nuclear fission process in producing industrial chemicals are discussed. Potential applications of these processes, such as production of ozone, fixation of nitrogen, and manufacture of carbon monoxide for pipeline gas, are described. Radiation and fission fragment chemistry data for these systems are summarized. The program of chemonuclear fuel development is described. The operational history of the chemonuclear loop is described, proceeding from initial dosimetry measurements to ozone synthesis from oxygen. The loop was installed in the Brookhaven Graphite Research Reactor. Budgetary restrictions prevented operation with chemonuclear fuel. The experiments were limited to the low-dose-rate neutron and gamma background radiation available from the Brookhaven Graphite Research Reactor. Despite this drawback, extremely encouraging results were obtained. Radiation yields (G-values) as high as 12 and ozone concentrations up to 500 ppM were achieved. This G-value compares favorably with the best yields obtained in carefully controlled laboratory experiments and was achieved in an all-metal, recirculating flow system (up to 425 csfm) with a high surface/volume ratio and at elevated pressures (up to 800 psi). The system was operated routinely by only two men and its operation was highly stable and reproducible. It was found that the addition of nitrogen enhanced the ozone concentrations obtained. It appears that at a given operating pressure, an optimum nitrogen concentration exists which results in maximum ozone concentration. The smooth operation of the chemonuclear loop and the high yields of ozone achieved represent an advance in nuclear technology and indicate that industrial chemicals can indeed be produced on a large scale by chemonuclear processes. (auth)

57611 (CTC-51) LABORATORY QUALITY CONTROL COMPUTER PROGRAM. Davis, M. H.; Hedge, W. D. (Union Carbide Corp., Oak Ridge, Tenn. Computing Technology Center). 1 Oct 1971. Contract W-7405-eng-26. 121p. Dep. NTIS.

An IBM System/360 FORTRAN IV computer program is described which is used to process quality control data for the laboratory Division, Oak Ridge Gaseous Diffusion Plant. The program can be used to screen quality control data on the basis of tolerance limits, and then compute the statistical quantities necessary to assist the Laboratory in the quality evaluation of measurement methods. The statistical techniques used in analyzing the data are discussed. Program features are described, and operating instructions are provided. A detailed description of the input and output data is given. Examples of the types of output generated are presented. (auth)

57612 (HEDL-TME-71-114) CCTL MARK II SUBASSEMBLY SHIPPING PROCEDURE TESTING AND AND SHIPPING REPORT. Edgar, J. B.; Tillson, D. D. (Hanford Engineering Development Lab., Richland, Wash.). Aug 1971. Contract AT(45-1)-2170. 73p. Dep. NTIS.

The method of shipping a Mark II test assembly, mounted on Pimcore foam and tied down with nylon straps in an exclusive use air-ride moving van, is described and was adequate to maintain the average acceleration intensity at less than 0.2g's vertical. Occasional shocks greater than 1.5g occurred, but were not prevalent. Analysis of data from test #8—Shok Foam with nylon tie-down—should be made to determine if additional improvements in reducing vibration and shock are possible. (auth)

57613 (JAERI-Memo-4446) CONCEPTUAL DESIGN OF THE REACTANT FLOW LOOP FOR FISSIOCHEMICAL STUDIES. Kiyose, Ryohei; Sato, Shoichi; Moriyama, Noboru; Ishii, Toshio; Hirata, Mitsuho (Japan Atomic Energy Research Inst., Tokyo). May 1971. 46p. (In Japanese). Dep. NTIS (U. S. Sales Only).

A conceptual design of a gas flow loop has been made for dynamic fissiochemical reaction studies. Heat generation and reaction yields in the reactor section of the loop are estimated assuming the radiation fields of JRR-4 (Japan Research Reactor–4, swimming pool type, with 2.5 MW), together with the temperature distributions in the reaction vessels using external gas cooling in which cooling is done by a third gas flowing outside jacket of the vessel and alternatively using internal gas cooling in which vessel temperature is controlled by the reactant gas itself. Fission product activities are also evaluated. The flowsheet of the loop is prepared which has a helium cooling system for temperature control of the nitrogen reactant gas. The main structural component, iron, is heated mainly by gamma radiation at a rate of about 0.32 W/cm^3, and the nitrogen is heated mainly by fission fragment energies released within the reaction vessel. A vessel designed to contain 5 foils of 20% U–Pd alloy, 2.5 μ thick, 6 cm in width and 10 cm in length will be heated at a rate of 50 kcal/hr, and the reactant gas at 7.2 kcal/hr. The volatile fission products I + Xe + Kr will have a total activity of 1 Ci, after 20 minutes operation of the loop. A practical loop design is presented, based on the proposed power-up plan of JRR-4. (auth) (Japan)

57614 (KFK-1387) CHANGE OF INTERPRETATION OF THE INTERMEDIATE HEAT EXCHANGER FOR THE SODIUM COOLED REACTOR USING FERRITIC STEEL DESIGN. Schnauder, H.; Mueller, R. A. (Kernforschungszentrum, Karlsruhe (West Germany). Institut fuer Reaktorentwicklung). Mar 1971. 26p. (In German). Dep. NTIS (U. S. Sales Only).

A comparison of the economics of a sodium/sodium intermediate heat exchanger design using ferritic steel and one using austenitic steel is made. A program system was available for the investigation which carries out the most important strength calculations in addition to the thermal design. Under constant operating conditions, the influence of the diameter of the heat exchanger tube and the wall thickness on overall costs as related to building volume and heating area is investigated and represented in curves. The influence of various operating parameters on the total costs is shown for the optimum tube diameters selected. (auth)

57615 (LA-4746) QUARTERLY STATUS REPORT ON THE SPACE ELECTRIC POWER R AND D PROGRAM FOR THE PERIOD ENDING JULY 31, 1971. PART I. (Los Alamos Scientific Lab., N. Mex.). Aug 1971. Contract W-7405-eng-36. 5p. Dep. NTIS.

Research and development progress is reported on heat pipe systems. Activities are summarized on tests of high-purity Li heat pipe, effects of impurities in heat pipes, and impurity removal methods. A method of constructing an in-pile test heat pipe is described. (J.R.D.)

57616 (LFEN-NI.-54-a) THERMODYNAMIC BEHAVIOR OF THE "MULTIFLASH" EVAPORATOR. Garcia, J. C. R.; Barros, Antonio A. S.; Costa, Augusto A. F. (Junta de Energia Nuclear, Sacavem (Portugal). Laboratorio de Fisica e Engenharia Nucleares). 1969. 31p. (In Portuguese). Dep. NTIS (U. S. Sales Only).

The solution of the problem of partial charge stability and operation of multiflash evaporators was studied. Definitions and equations are derived. The degree of approximation in the various hypotheses is analyzed. Experimental models in the design stage are used in the calculations. (J.S.R.)

57617 (N-71-26910) BALL BEARING DESIGN FOR THE SNAP-8 TURBOALTERNATOR AND MERCURY PUMP. Foley, R. S. (Aerojet-General Corp., Azusa, Calif.). May 1971. Contract NAS5-417. 81p. (NASA-CR-72825). NTIS.

The design and application of angular-contact, tool-steel ball bearings used in the turbine-alternator and the mercury pump of the SNAP-8 electrical generating system are reported. These SNAP-8 rotating machines run on ball bearings with a design objective of 99.5% reliability for 10,000 hours of continuous operation. A summary of ball bearing operating experience through September 1970 is presented. The bearing design selected for operation in the SNAP-8 system has exceeded the original life objectives, and has operated in excess of 23,000 hours. From the experience gained to date, it is anticipated that bearing life of five years or greater is feasible. (auth) (STAR)

57618 (ORNL-TM-3570) FAILURES OF THREADED FITTINGS AND FASTENERS AT NUCLEAR FACILITIES. Scott, R. L.; Harley, P. H. (Oak Ridge National Lab., Tenn.). Oct 1971. Contract W-7405-eng-26. 19p. Dep. NTIS.

Thirty-three incidents are tabulated concerning problems encountered with bolts, screws, nuts, and threaded fittings, all of which should be of interest to both designers and operators. These incidents have required approximately 70 months of additional reactor downtime. One facility estimated an expenditure of $10,000 caused by the failure of a 1-in. threaded strainer plug. The three major types of failures, corrosion, fatigue, and galling, are discussed. (auth)

57619 (RFP-1739) INVESTIGATION OF FLUORINE INTERACTIONS WITH COMMON GLOVEBOX CONSTRUCTION MATERIALS. Meile, Louis J.; Wing, Ralph O. (Dow Chemical Co., Golden Colo. Rocky Flats Div.). 13 Sep 1971. Contract AT(29-1)-1106. 6p. Dep. NTIS.

The interactions between common glovebox construction materials and fluorine gas (F_2) were investigated to ascertain the potential safety hazards of handling high pressure fluorine within a glovebox system. Construction materials from volatile-fluoride, plutonium recovery gloveboxes at Rocky Flats Plant were tested in various fluorine and air mixtures at concentrations of 1 to 100 percent. All of the materials tested remained stable in fluorine concentrations of 10 percent, which is the calculated maximum anticipated in the event of a major fluoride release within the prototype gloveboxes. Many test materials spontaneously ignited in fluorine concentrations exceeding 25 percent. Combustion spread rapidly between close-proximity test samples in a fluorine atmosphere. Data reported are for static gas conditions at specified temperatures. Conclusions are given with a list of recommendations for use of fluorine within a glovebox system. (auth)

57620 (RISO-204) LOW-TEMPERATURE IRRADIATION FACILITY FOR HEAVY-ION RADIATION DAMAGE STUDIES

XUM

OF METALS. Andersen, H. H.; Simonsen, H.; Soerensen, H. (Danish Atomic Energy Commission, Risoe. Research Establishment). Mar 1971. 59p. Dep. NTIS (U. S. Sales Only).

A liquid-helium temperature facility for irradiation of thin metal foils with MeV protons, deuterons, ^{3}He, and ^{4}He was built in connection with the Tandem van-de-Graaff accelerator of the Niels Bohr Institute. The set-up includes a beam handling system (focusing devices and a beam sweep to create a homogeneous flux over the target area) and a liquid-helium cryostat with a built-in calorimetric dosimetry system (absolute accuracy 0.5%). Changes in electrical resistivity of the irradiated samples are measured with a superconducting chopper amplifier system with a dc sensitivity of 3×10^{-12} V and a relative reproducibility of 1 in 2×10^5. The performance of the facility is described in detail, and the data handling is discussed together with the necessary corrections to the experimental data. (auth)

57621 (TRG-Report-2141) ACOUSTICALLY INDUCED VIBRATIONS OF SLENDER RODS IN A CYLINDRICAL DUCT. VOLUMES I AND II. Hine, Michael John (Southampton Univ. (England)). Jan 1971. 185p. Dep. NTIS (U. S. Sales Only). Thesis.

The nature of acoustically-induced transverse vibrations of slender rods contained within a fluid-filled cylindrical duct was investigated for both single rods and rod clusters. The effect of low Mach number fluid flow on acoustically-induced rod response was also studied. (UK)

57622 SPECIAL VEHICLE FOR FIGHTING DAMAGES IN TERRAINS CONTAMINATED WITH ABC SUBSTANCES. Haas, Willy (to Daimler-Benz Aktiengesellschaft). U. S. Patent 3,567,273. 2 Mar 1971. Priority date 17 Nov 1965, Germany.

A vehicle is described for use in areas contaminated with atomic, biological and chemical substances or war materials, having a driver cab provided with built-in communication equipment and devices for determining radiation levels existing in the immediate environment of the vehicle, a center section having radiation-measuring apparatus and one or more devices for cleaning contaminated persons or objects, and a rear body section having water tanks, pumps and other necessary equipment. (Official Gazette)

57623 JET-MIXED LIQUID-LIQUID EXTRACTION COLUMN. Vermeulen, Theodore; Kahn, Daniel R. (to United States Atomic Energy Commission). U. S. Patent 3,574,558. 13 Apr 1971. Filed 6 May 1969.

A jet-mixed extraction column which incorporates the advantages of existing column-type extractors, while eliminating the need for internal moving parts is described. The column provides high rates of mass transfer, with only normal or even decreased extents of unwanted longitudinal dispersion compared to various prior column-type extractors. The column utilizes uniformly spaced, horizontal, tubular jetting and intake rings at the inner and outer boundaries of an annular cross-section. At each level, both rings are perforated so as to promote nearly straightline radial flow between the jetting and intake rings. Externally these rings are connected by way of a centrifugal circulating pump or a double-action reciprocating pump. (Official Gazette)

57624 PLUGGING COMPOUND COLLECTOR. Blair, Roy C. (to United States Atomic Energy Commission). U. S. Patent 3,554,374. 12 Jan 1971. Filed 2 Jul 1968.

A device is described for selectively extracting impurities from sodium coolant for subsequent analysis, identification and/or disposal. This is accomplished by arranging a battery of demountable, narrow sodium flow passages in a system where sodium temperature can be controlled. As sodium temperature decreases, any impurity will precipitate and collect on the flow passage walls when its equilibrium solubility is exceeded. The demountable arrangement of the device allows easy access to the collected material for removal and identification or disposal. (Official Gazette)

57625 IMPROVEMENTS IN OR RELATING TO IRRADIATION. (to Sulzer Brothers Ltd.). British Patent 1,230,950. 5 May 1971. Priority date 5 Dec 1968, Switzerland.

A method of irradiating articles is described in which the material to be irradiated is enclosed in a medium capable of combining with oxygen. The irradiation package is gas-tight and the materials are in contact with the contained gases during irradiation. Using this method, materials can be radiosterilized and deoxygenated simultaneously. (J.R.D.)

57626 K SERIES CENTRIFUGES (6 Jul 1971) (Engineering Materials). (Oak Ridge Gaseous Diffusion Plant, Tenn. Oak Ridge National Lab., Tenn.). (CAPE-1681(Rev.)). 28 drawings.

High-capacity zonal centrifuges in the K series are described. The K-II was designed for purification of influenza virus at a rate of ~100 liters/day making the instrument commercially feasible. The operating mode is continuous flow-with-banding using a tapered core with six vanes (similar to the B-IX core described in CAPE-1415). The rotor has a single path fluid-line seal at each end that eliminates the possibility of cross leakage between inlet and outlet streams. The air turbine drive is a modified commercial item. The K-XII zonal rotor is an improved K-II rotor, which eliminates the speed-dependent back pressure developed on the end and core caps by the K-II at a speed of 35,000 rpm. Seal leakage is also lowered. The incorporated improvements are applicable to all K-series cores and rotors. (For details see TID-4100 Suppl. 65). (F.S.)

57627 AUTOMATED CAMERA FOR HOT CELL METALLOGRAPHY. Bender, J. H.; Johnson, K. A. (Los Alamos Scientific Lab., N. Mex.). pp 19-23 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From 3. meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

Standard equipment modification and re-design permits the use of a viewing screen with a swing-out mirror in combination with a 70 mm roll film magazine. The associated electric shutters and timers, automatic film advance and integrated identification system are discussed. (auth)

57628 CONTROL OF AN INSTALLATION FOR THE IMPREGNATION AND GAMMA IRRADIATION OF WOOD. THE DEVELOPMENT AND PROGRAMMING OF A COMPUTER CONTROL SYSTEM. Silie; Worm; Taieb (Ecole Superieure d'Ingenieurs d'Electrotechnique et d'Electronique, Paris). Elec.-Electron. Mod.; 41: No. R251, 14-16; 27(Feb 1971). (In French).

The active part of the irradiator is divided into 5 parts, corresponding to the occupation of the irradiator by five different lots. Each time the first basket of a lot enters a new phase, the velocity is varied. The integrated dose is thus the sum of the five partial doses obtained with the successive velocities V1, V2, V3, V4, and V5. The computer must therefore control the treatment chain and the irradiation doses, and must perform the three following operations: calculation of the velocity associated with a given lot, calculation of the partial dose received associated with the velocity of the chain, and the calculation of the mean velocity associated with the velocities of the different lots. The order of magnitude of the voltages and resistances, the number of circuits necessary, and the read-out systems for the various parameters are studied. (France)

57629 AUTOMATIC ULTRASONIC INSTALLATION FOR DECONTAMINATION OF FOOTWEAR ON HUMAN LEGS. Vylezhnin, I. A.; Gol'dshtein, D. S.; Gorodinskii, D. S.; Kobylkin, A. F. (Moscow Inst. of Biophysics). Izotopy SSR; No. 17, 39-41(1970). (In Russian).

An ultrasonic facility for decontaminating footwear of personnel handling β- and β-γ active materials is described. The decontamination facility is highly efficient and prevents the possibility of contaminating the environment. (tr-auth)

57630 IMPROVEMENTS IN OR RELATING TO HEAT EXCHANGERS. Coles, Harold John (to Atomic Power Constructions Ltd.). British Patent 1,244,611. 2 Sep 1971. Filed 1 Dec 1967.

Reference is made to heat exchangers of the helical type, and the construction described is claimed to provide an exchanger that is easier and cheaper to assemble than some constructions previously used. This exchanger comprises a number of tubes, with transverse support members, and suitable attachment members. The support members are of elongated shape and are supported at at least one end, the tubes being arranged in parallel layers with support members between adjacent layers, and the attachment members of a layer of tubes are used to carry the support members of the next adjacent layer. The attachment members may take the form of suitable clips, and the tubes may be substantially in the form of helices fitting one inside the other. A number of alternative geometrical arrangements are described, together with constructional methods. (UK)

57631 PHYSICAL MEASUREMENTS ON A ^{60}Co IRRADIATION UNIT. Burlin, T. E.; Chan, F. K. (Polytechnic, London). Int. J. Appl. Radiat. Isotop.; 22: 73-83(Feb 1971).

The physical properties of a ^{60}Co irradiation unit were measured. Particular attention was paid to those aspects of the radiation field inside the radiation cell about which there is no information in the literature. The photon field has a large electron contamination, which would lead to an excess dose in the surface layers of irradiated objects. The photon energy spectrum is considered—about 20% of the photons in the irradiation cell arise from scattering processes. The exposure rate is measured by three methods and the exposure distribution presented. (auth)

57632 LEAK DETECTION IN SODIUM HEATED BOILERS. Hayes, D. J.; Horn, G. J. Brit. Nucl. Energy Soc.; 10: 41-8(Jan 1971).

Freedom from leaks in the sodium–heated boilers of a civil fast reactor cannot be guaranteed. Reliable procedures must be available so that the operator can detect, locate and isolate a leak with minimum interference to the running of the plant. Detection of a leak and isolation of the faulty unit should be achieved before the possibility of adjacent tube failure due to erosion. Analysis of available erosion data indicates that for $2\frac{1}{4}$ Cr–Mo material a leak as small as 100 μm dia could cause such a failure in a period of the order of 1 min. The design and performance of possible leak detection systems based on the detection of hydrogen in the sodium system are analyzed and discussed. (auth)

57633 MELCHETT LECTURE, 1970. THE FUTURE OF POWER GENERATION IN GREAT BRITAIN. **Allibone, T. E. (Central Electricity Generating Board, London).** J. Inst. Fuel; 44: 85-91(Feb 1971).

The pattern of growth of electrical generation and distribution, in Great Britain, during the next 30 yr is considered. Attempts are made to define the major changes in the balance of the fuels, coal, oil, gas, U, and H. The discussion includes a description of the growth and economics of nuclear power. It also envisages future prospects for thermonuclear devices, magnetohydrodynamics and the potential use of superconducting cables for power transmission. (UK)

57634 IMPROVEMENTS IN BEARINGS. **(to Messerschmidt-Boelkow-Blohm Gesellschaft Mit Beschraenkter Haftung). British Patent 1,245,894.** 8 Sep 1971. **Priority date 23 Apr 1968, Germany.**

A design is described for bearings of the kind in which a lubricant pressure support is utilized, the bearing, in use, being immersed in a lubricant bath, and the lubricant pressure being generated hydrodynamically in a wedge shaped gap between bearing surfaces of a body having a spherical bearing surface and a cup having a complementary bearing surface into which the body fits, the cup being provided with bores and grooves for the introduction of lubricant, and its bearing surface being divided by slits into segments which can deflect under load. Bearings of this kind are used for rotors turning on a vertical axis, such as ultracentrifuges, and often have to support the entire weight of the rotor, thus being subjected to considerable strain. This design results in a bearing which in use has a film of lubricant of reliable supporting capacity, which will not break up, formed between the bearing surfaces when moving at relatively high speed, which film will be maintained so that the supporting capacity of the bearing is improved, and its length of useful life increased, by comparison with known bearings. (L.C.L.)

57635 PRESSURE CELLS (8 Sep 1969) (Engineering Materials). **(California Univ., Livermore. Lawrence Radiation Lab.). (CAPE-2117).**
2 drawings.

Two pressure cells are described which are used in obtaining equilibrium thermodynamic data for liquid metals at high temperatures and pressures. A specimen of wire one mm in dia and 25 mm long is mounted between two current leads so that it is actually concentric with the cell. The cell is filled with He to the desired working pressure. A current pulse of controlled magnitude and duration, from the overdamped discharge of a high voltage capacitor bank, heats the wire to the desired state at a rate such that expansion is nearly isobaric. Energy deposited in a segment of the sample is calculated from data obtained by measuring the current through the sample and the potential difference between two probes spaced about 5 mm apart near the center of the specimen. From this collected data resistance is calculated. The thermodynamic specification of the high-temperature state is completed by measuring the expanded dia of the sample using x-radiographic techniques. Temperatures exceeding 5000°K at pressures up to 2 kbar have been reached with Pb. In the 3 kbar cell, construction is axial. The cell bottom is sealed with a steel plug that carries the plumbing required for gas transfer. Top and bottom seals are "O" rings that float between brass wedge rings and a 45° bevel on the opening in the Be cylinder. A Cu plug, through which three Cu leads pass, seals the top. These leads carry current to the sample and return voltage signals from the two voltage probes. Brass sample supports and current leads offer mechanical strength without sacrificing electrical conductivity. The top sample support is fitted with a notched end plate attached with a screw to securely clamp the sample and to provide electrical contact. The bottom support is cantilevered from a rod attached to the top plug of the cell to give support axially and symmetrically to the cell. Three Cu or tinned Cu rods extend downward into a plane through the axis of the sample. These rods are oriented with respect to two x-ray sources. The rods serve as calibration rods for the determination of the dia of the expanded sample. The cell is enclosed in a steel cylinder which provides rupture containment. Two major improvements are incorporated in the 7 kbar cell. The Be cell is supported by a steel sleeve. One inch square openings provide x-ray windows and a method for providing seal preload sufficient to maintain the seal is utilized. In the 3 kbar cell, pressure is provided by residual pressure in three reservoirs through appropriate valves and tubes. Pressures in the reservoirs are 1500, 5500 and 25,000 psi. An air driven oil pumping system is employed in the 7 kbar cell. This system supplies oil pressure for operating a seal-loading ram and an oil-gas separator. The pump can be connected to the ram, separator, and intensifier separately, thus making it possible to vary gas pressure and the seal load in incremental steps to achieve any desired pressure. (For details see TID-4100 Suppl. 66) (see also 25: 35342) (F.S.)

57636 FLUID IRRADIATING APPARATUS USING GAMMA RAYS AND HELICAL PASSAGEWAYS. **Mann, Leland A.; Woodbridge, David D.** (to Energy Systems, Inc.). **U. S. Patent 3,602,712. 31 Aug 1971. Filed 17 Feb 1969.**

A radioactive apparatus is provided for the sterilization and treatment of liquids and especially for the sterilization and treatment of liquid waste such as sewage and industrial waste by the use of gamma radiation sources. A spiraling input chamber spirals around a center chamber having an elongated core member with a helical pipe forming a helix or coil around said hollow member in the center chamber. Liquid waste being received by the apparatus passes through the spiraling chamber into the center chamber, into and through the elongated hollow member and then through the helical pipe to an output. Gamma radiation sources are located around the helical pipe in such a manner as to provide an efficient use of the radiation sources. (Official Gazette)

57637 DESIGN OF SAFETY VALVES AND THE LIKE FOR BWR-TYPE POWER STATIONS. **Ito, Mutsumi; Fujii, Takenori; Aoki, Tsuyoshi (Tokyo Shibaura Electric Co. Ltd., Kawasaki, Japan). Karyoku Hatsuden: 22: No. 1, 59-64(Jan 1971). (In Japanese).**

The design of safety and relief valves attached to reactor pressure vessels, according to MITI regulation revised in 1970, is described. The regulation was revised so that in the case of equipment provided with overpressurization preventing devices, the capacity of the safety valves could be reduced. This means that the effects of a reactor scram on reduction of pressure can be taken into account. Therefore, in order to design total capacity of the safety and relief valves, it is necessary to analyze the transient state of plants following such disturbances as turbine trip with a dynamic characteristic model of the plants. The transient conditions analyzed for the design of the valves are as follows: while a turbine is running under heavy load, that is 105% of the rated output, the turbine is tripped but bypass valves do not operate and the turbine trip scram fails and overpressurization of a reactor vessel is controlled by the safety and relief valves. Other means to prevent the overpressurization considered is reactor scram by detection of high neutron flux or high pressure. Sharing of required capacity between the valves is engineered so that the high pressure spring-type safety valves never blow off in case of the overpressurization which is likely to happen frequently during plant operation. The conditions analyzed for the design of the safety relief valves are turbine trip, followed by reactor scram due to the turbine trip, with failure of the bypass valves to operate. (Japan)

Heat Transfer and Fluid Flow

Refer also to abstracts 57615, 57621, 57630, 57667, 57674, 58233, 58357, 60059, and 60222.

57638 (IAE-2014) HEAT EXCHANGE CRISIS DURING MOVEMENT OF BOILING WATER ALONG FUEL ROD BANKS. **Osmachkin, V. S. (Institut Atomnoi Energii, Moscow (USSR)). 1970. 16p. (In Russian). Dep. NTIS (U. S. Sales Only).**

An analysis was made of the factors affecting the current conditions of heat exchange crisis in rod bundles. A formula is proposed for calculating the critical thermal loads in the fuel rod bundles generalizing the experimental data of various authors in a wide range of velocities, pressures, steam contents by weight at the channel output, and bundle lengths. (tr-auth)

XUM

57639 (JUL–753-RB) HEAT TRANSFER OF TUBE SHAPED FUEL ELEMENTS OF THE CENTRAL CHANNEL OF A REACTOR OF THE TYPE NATURAL URANIUM-GAS-GRAPHITE. Broeckerhoff, Peter (Kernforschungsanlage, Juelich (West Germany). Institut fuer Reaktorbauelemente). Apr 1971. 106p. (In German). Dep. NTIS (U. S. Sales Only).

With respect to both heat and flow dynamics, design of tube-shaped fuel elements was studied which were cooled externally and internally and which were planned for a natural uranium-gas-graphite-type reactor. Equations were derived for calculating the cooling medium distribution between external and internal channels. Mathematical results were compared with experimental results on smooth and ribbed tube models. Various types of cooling ribs were tested. To assess the heating efficiency of tube-shaped fuel elements under typical reactor conditions, a special computer program was developed. Computations were performed for a fuel element of 9m length and with sine-wave shaped flux distribution. Because of limitations set by the cladding temperature, external and internal cooling ribs could remove only 3.5 times more heat than smooth tubes. The lowest pressure loss occurred with longitudinal internal cooling ribs, which had the additional advantage of lowest manufacturing cost. (H.B.G.)

57640 (N–71–22591) INDUCTION PLASMA NOZZLE TESTS. Poole, John W.; Vogel, Charles E. (Humphreys Corp., Concord, N. H. TAFA Div.). Apr 1971. Contract NAS3-13227. 48p. (NASA-CR–1765). NTIS.

An experimental program was conducted to establish induction coupled arc plasma systems with high exit gas enthalpies which could be used to study various nozzle designs. The objective of this work was closer simulation of the nozzle environment expected in the Gas Core Nuclear Rocket. Air plasmas with enthalpies up to 13,000 Btu/lb were developed and evaluation of transpiration-cooled and seeded-transpiration cooled nozzles was conducted. It was shown that transpiration cooling reduces the thermal load to the nozzle and the seeded-transpiration cooling further reduces the thermal load. (auth) (STAR)

57641 INTERACTIONS OF RADIANT ENERGY WITH SMALL PARTICLES IN HOT, HIGH PRESSURE GASES. Partain, William Lee Jr. Atlanta; Georgia Inst. of Tech. (1970). 165p. University Microfilms Order No. 71-6423.
Thesis.

Aerosols of submicron-sized refractory particles are being considered as coolants for gas core reactors and for thermal radiation shielding in nuclear rocket nozzles. In order to be useful for these applications, the particles should be strongly absorbing in the ultraviolet, visible and near infrared regions of the spectrum and should withstand high temperatures at high pressures without reacting or vaporizing. Submicron-sized particles of refractory metals generally satisfy both of these requirements. The ability of dispersed particles to absorb thermal radiation is determined by the extinction parameter, the scattering parameter and the angular scattering characteristics of the particles. Measurements are needed of these heat transfer parameters as functions of temperature, pressure, and incident radiant energy wavelength in order to evaluate the propellant heating in gas core nuclear rocket engines. Measurements of the extinction parameter of tungsten-hydrogen aerosols were made as a function of wavelength from 2500 to 5800 Å at pressures to 115 atmospheres and temperatures to 2500°K. High pressure hydrogen, first unseeded and then seeded, was heated in a furnace employing an electrically heated tungsten strip. Radiant energy from a high pressure mercury arc was passed through the furnace, and measurements of the transmitted radiation and of the aerosol density yielded the extinction parameter for the tungsten-hydrogen aerosol at the selected temperature and pressure. The measured extinction parameter at room temperature for all pressures to 115 atmospheres compared well with the theoretical value of the extinction parameter calculated using the Mie theory. The extinction parameter was observed to increase with pressure at temperatures above about 1000°K. Whereas the extinction parameter had been shown earlier to increase about a factor of two, from room temperature to 2000°K, at one atmosphere pressure, the increase was found to be about a factor of four at about 10 atmospheres and much greater at 100 atmospheres pressure. According to the Mie theory, the breaking up of particle agglomerates could account for part of this increase, but not all. Several physical processes are discussed that might be excepted to enhance photon extinction beyond that predicted by the Mie theory. (Diss. Abstr. Int., B)

57642 TRANSIENT FILM AND TRANSITION BOILING FROM A SPHERE. Stevens, J. W.; Witte, L. C. (Univ. of Houston, Tex.). Int. J. Heat Mass Transfer; 14: 443-50(Mar 1971).

The nature of transition boiling from $^3/_4$ in. dia copper sphere moving through subcooled distilled water was experimentally investigated. High-speed photographs show that transition occurs as a rapidly pulsating vapor film on the forward portion of the sphere. The behavior of the vapor wake is highly dependent upon the manner in which vapor is being formed on the forward portion of the sphere. Instantaneous heat transfer rates calculated from experimental temperature-time measurements indicate that film and transition boiling are as effective as nucleate boiling over the velocity range from 9.6 to 20.0 fps, in highly subcooled water. That is, there is no significant change in the heat transfer rate at transition as observed for free convection quenching of spheres.

57643 MEASUREMENT OF THE EFFECT OF TWISTED TAPES ON THE FORCED-CONVECTION HEAT TRANSFER AND BURNOUT IN HEAT EXCHANGERS. Brevi, R.; Cumo, M.; Palmieri, A.; Pitimada, D. (Comitato Nazionale per l'Energie Nucleare, Rome). Nucl. Sci. Eng.; 46: No. 1, 131-9(Oct 1971).

Very promising results with the insertion of twisted tapes in tubular heat exchangers have suggested performance of experiments under more interesting conditions, i.e., at higher pressures (50 atm) with exchangers of larger dimensions (200 cm in length and 1-cm i.d.). The results show a great increase in the forced-convection heat transfer coefficient ranging from 100 to 150% at specific mass flow rates of 70 to 100 g/(cm^2 sec). The law of dependence of the Nusselt number on the Reynolds number varies with an exponent unity instead of 0.8. The burnout thermal power increases by 30 to 50%; correspondingly, the burnout qualities increase from 60 to 90%, thus drastically reducing the post-burnout length. Furthermore, within this length there are no characteristic, dangerous temperature oscillations. The present results, together with others cited in the referenced literature, constitute a basis for improvement of the subcritical one-through heat exchangers for pressurized-water and liquid metal fast breeder reactor power plants. (auth)

57644 THERMAL CONTACT RESISTANCE BY REFLECTION OF HEAT DIFFUSION WAVES. Robinson, M. J.; Tomsic, M. (Kansas State Univ., Manhattan). Nucl. Technol.; 12: No. 4, 393-403(Dec 1971).

The applicability of the temperature wave method to thermal contact conductance measurements is investigated. The theoretical analysis shows that the amplitudes and the phase angles of the reflected and the transmitted temperature waves at the contact depend on the contact conductance, the ratio of the thermal conductivities, and the thermal diffusivities of the two solids. Measurements for stainless steel—aluminum specimen pairs confirm the theoretically predicted dependence. The accuracy of the method is comparable to that of the steady flow method. Since periodic heat flow and small temperature gradients are used the method has some advantages over the steady flow method and in particular some special features of contact conductivity phenomena may be studied. (auth)

57645 AIR FLOW THROUGH CONCENTRIC DUCTS SEPARATED BY A POROUS PIPE. Berger, F. P. (Queen Mary Coll., London); Blake, J. P. H. J. Brit. Nucl. Energy Soc.; 10: No. 3, 217-28(Jul 1971).

Experiments on air flow through concentric cylindrical ducts separated by porous pipes were carried out as a contribution to the assessment of porous fuel elements for the gas-cooled fast reactor concept. The experiments comprised measurement of the axial pressure distribution in both ducts, of the velocity in the axis of the inner duct, and of velocity profiles in the outer duct. A computer program describing the flow distribution in such a system was developed. When pressure recovery and pressure loss factors derived from the experiments were included in the program, the calculated flow patterns were in fair agreement with the experimental ones. (auth)

57646 IMPROVEMENTS IN OR RELATING TO FLOW PRESSURE MEASUREMENT. Davidson, Daniel Fraser (to United Kingdom Atomic Energy Authority). British Patent 1,234,210. 3 Jun 1971. Filed 2 Nov 1967.

Reference is made to methods for the measurement of liquid metal flow pressures, such as the delivery pressure of liquid metal pumps. The instrument described comprises a duct having low resistance to liquid flow, adapted for incorporation in the flow path. Means are provided for setting up a magnetic field across the duct, together with a pair of opposed electrodes for conduction of current generated by flow of the liquid metal through the magnetic field. The current induced in the liquid metal is circulated across the duct by way of a low resistance shunt between the electrodes, the electrical resistance of the shunt being substantially equal to the resistance of the liquid metal between the electrodes. Means are provided for measuring the potential difference between the electrodes, which is related to the liquid metal pressure. The low resistance shunt may be a Cu or Ag coating on the duct. (UK)

57647 BURN-OUT IN TRANSIENT BOILING HEAT TRANSFER. Sakurai, Akira (Kyoto Univ., Uji, Japan). Kyoto Daigaku Kogaku Kenkyusho Iho; No. 38, 1-14(Oct 1970). (In Japanese).

Transient boiling heat transfer and burnout are most important studies related to the safety analysis of reactor accidents. Burnout in transient boiling heat transfer is reviewed using previously published experimental data and theoretical analysis. First, critical heat flux and heat flux in departure from nucleate boiling is explained with a boiling curve. Secondly, from transient boiling experiment at Oak Ridge National Laboratory, the relation between the critical heat flux and the exponential period of heat flux at incidence of film boiling is presented, and then, analytical studies by various researchers are described. A new experimental apparatus for determining transient boiling burnout is proposed and principal experimental results are summarized. (Japan)

57648 VOID FRACTION MEASUREMENTS IN TWO-PHASE AIR-WATER FLOW IN A VERTICAL CHANNEL BY GAMMA RAY ATTENUATION. Siva Kumar, M.; Srikantiah, G. (Indian Inst. of Tech., Kanpur). Indian J. Technol.; 9: No. 4, 125-8 (Apr 1971).

The variation of void fraction and slip ratio with pressure and air weight fraction for the flow of a two-phase mixture of air and water in a vertical channel were measured by the γ-ray attenuation technique. The test section used was an aluminum pipe of square cross-section (3.33 cm^2). The pressure was varied in the range from 3.0 to 12.5 psig, and the air weight fraction in the range 0 to 3.6%. The void fraction was found to increase with pressure due to the sharp reduction in slip ratio. A scan of void distribution across the section showed that the voids have a tendency to concentrate near the center of the pipe. The experimental results were compared with those predicted. The agreement between the experimental and theoretical results is not satisfactory. Further analysis of the results indicated that the flow was in the bubbly regime, though the transition region was approached at higher values of void fraction. (auth)

Isotope Technology

Refer also to abstracts 57498, 57500, 57521, 57613, 57615, 57631, 57636, 57696, 57697, 57701, 57707, 58180–58182, 58242, and 59632–59640.

57649 (CONF-711002–, pp 1-9) PREPARATION OF NUCLEAR RESEARCH MATERIALS WITH A LABORATORY-TYPE ISOTOPE SEPARATOR. Lerner, Jerry (Argonne National Lab., Ill.). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Development of laboratory-type isotope separators is reviewed. A typical separator is described and it is noted that such separators are extensively used for process research materials for nuclear measurements because they can both purify the desired isotopes and also deposit them in the form required by the nature of the experiment. Applications include targets for cyclotron, Van de Graaff and synchrotron accelerators, sources for alpha, beta, gamma spectroscopy, Mössbauer studies, and optical pumping experiments. (J.R.D.)

57650 (CONF-711002–, pp 10-20) USE OF AN ELECTROMAGNETIC ISOTOPE SEPARATOR IN PREPARING SPECIAL RESEARCH SAMPLES. Alton, G. D.; Love, L. O. (Oak Ridge National Lab., Tenn.). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

The isotope separator was first used by the Europeans in the early 1950's in the preparation of thin, isotopically enriched accelerator targets, beta spectroscopy samples, and radioactive sources. Aside from the practical advantage of direct deposition, samples which are prepared in an electromagnetic isotope separator are generally of superior chemical and isotopic quality. The separator is also in increasing demand for use in modifying the chemical composition and physical properties of solid surfaces by implanting energetic particles into these surfaces. The isotope separator has been used to great advantage for doping semiconducting materials because the choice of dopants is no longer governed by the solubility limits or diffusion kinetics of the materials in question. The principal advantages of injecting dopants in this manner is in the preciseness in which uniformity, quantity of injected material, and depth of penetration can be controlled. In preparing samples for various uses in an isotope separator, the isotopic or elemental materials are collected directly; therefore, the limits of collection are controlled by the energy dependent, ion-surface interactions. In the keV energy range, the quantity of material per unit area is limited to the saturation value due to the fact that the self-sputtering ratio of the material is greater than one. If the quantity per unit area of material is to be increased, it is necessary to decrease the incident particle energy in order to permit the building up of layers. At this reduced energy, the efficiency of collection is governed by the value of the self-sputtering ratio and the probability that a particle will stick to the surface. Self-sputtering ratios, saturation values, and collection curves as a function of energy are used as fundamental guidelines in target and sample preparation with an isotope separator. Descriptions of the calutron system and the 180° ORSIS system are included. (auth)

57651 (CONF-711002–, pp 147-59) THIN FILM RADIATION SOURCES BY RADIOFREQUENCY SPUTTERING. Jarrett, J. H. (Battelle Pacific Northwest Labs., Richland, Wash.). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Preparation of thin film radiation sources by radiofrequency sputtering is described. Information and discussions are included on source design, source preparation, source properties, and source testing. A discussion of forecasted source developments is included. (J.R.D.)

57652 (DAISE–70-8) HEAVY WATER PRODUCTION, INDUSTRIAL PROCESSES, AND PLANTS. A Bibliography. Lavrencic, D. (comp.) (Comitato Nazionale per l'Energia Nucleare, Rome (Italy)). 1970. 314p. INIS.

The bibliography, covering the period from 1946 to June 1970, is arranged under the following items: General; Determination and Analyses; Production Processes and Fabrication Plants; Heavy Water Reactors; and Heavy Water Reactors in Nuclear Power Programmes. An author index is also included. (INIS)

57653 (DP–1270) HOT PRESSING TECHNIQUES FOR FABRICATING Cm_2O_3 FOR RADIOISOTOPIC FUEL FORMS. Rankin, D. T. (Du Pont de Nemours (E.I.) and Co., Aiken, S. C. Savannah River Lab.). Sep 1971. Contract AT(07-2)-1. 19p. Dep. NTIS.

Hot pressing techniques were developed for fabricating bulk oxide and oxide-refractory metal cermet fuel forms, using Gd_2O_3 as a stand-in for $^{244}Cm_2O_3$. High-density (95% theoretical) B-type oxide compacts were produced by pressing C-type oxide at 1200°C and then heating under pressure to 1300°C where the B-type oxide forms, or by direct pressing at higher temperatures (1500°C) in the B-type oxide range. High-density (>90%) cermet compacts containing 50 to 70 vol % oxide in tungsten or molybdenum matrices were also made by hot pressing. Most of the residual porosity for these structures was open and available for release of decay helium. (auth)

57654 (DP–1279) SAVANNAH RIVER LABORATORY ^{60}Co POWER AND HEAT SOURCES. Quarterly Progress Report, April–June 1971. Angerman, C. L.; Ross, C. P. (comps.) (Du Pont de Nemours (E. I.) and Co., Aiken, S. C. Savannah River Lab.). Aug 1971. Contract AT(07-2)-1. 19p. Dep. NTIS.

Satisfactory performance through 20,000 hr at 900°C was demonstrated with an Inconel 600 capsule containing unirradiated cobalt metal. Superalloys reacted slightly more with soil than with air during exposures at 1000 and 1093°C for one year. Satisfactory performance through 1000 hr at 1200°C was demonstrated with a tungsten capsule containing unirradiated cobalt metal. Results of additional oxidation tests of Nickel 200, which is similar to the Nickel 201 that is being used as the core material in the WANL 30 kW(t) Unit, indicate a slower oxidation rate than predicted from previous tests. A thermoelectric generator fueled with ^{60}Co continued to operate satisfactorily with an electrical output of 77 watts. (auth)

57655 (MLM–1844) NEUTRON EMISSION RATE REDUCTION IN PuO_2 BY OXYGEN EXCHANGE. Chadwell, C. B.; Elswick, T. C. (Mound Lab., Miamisburg, Ohio). 24 Sep 1971. Contract AT-33-1–Gen-53. 6p. Dep. NTIS.

A method was developed to produce $^{238}Pu^{16}O_2$ depleted in oxygen-18 and oxygen-17 on a routine production basis. The method is a gas phase-packed bed method which was used successfully on both low-fired and high-fired $^{238}PuO_2$ particles. Average neutron emission rates of 4.6 × 10^3 n/sec/g of plutonium-238 were obtained on production batches with average weights of 250 g plutonium-238. (auth)

57656 (N–71-18512) THERMIONIC ENERGY CONVERSION SYSTEM DESIGN. Final Technical Report. De Steese, J. G. (McDonnell Douglas Astronautics Co., Richland, Wash. Donald W. Douglas Labs.). Jan 1971. Contracts NAS7-100; JPL-952781). 193p. (NASA-CR-116795; MDC G–2024). NTIS.

For Jet Propulsion Lab., Pasadena, Calif.

System integrated performance characteristics are calculated

XUM

for a new family of space power generators each consisting of a multicell array of low temperature, integrally-fueled radioisotope thermionic converters operating in the quasi-vacuum mode. Dominant variables, including the choice and influence of thermionic surface parameters, emitter geometry, fuel form, helium management, array reliability, system integration, and nuclear safety requirements are considered. Parametric study of plutonia-fueled multicell generators in the power range from 100 to 200 W(e) shows that system integrated specific power of approximately 4 W(e)/lb and overall conversion efficiencies in excess of 7% are achievable. This performance level is substantiated by a detailed 100 W(e) generator design. (auth) (STAR)

57657 (NUMEC-4189-6) RADIOISOTOPE POWERED CARDIAC PACEMAKER PROGRAM. Quarterly Progress Report for Phase II, May 1–July 31, 1971. (Nuclear Materials and Equipment Corp., Apollo, Pa. Energy Conversion Div.). Aug 1971. Contract AT(30-1)-4189. 32p. Dep. NTIS.

The results of developmental work on an implantable Radioisotope-Powered Cardiac Pacemaker (RPCP) are reported. Preparations for pilot production of RPCP's continued. All the fixtures and a complete tentative set of written procedures for such production were completed. During this report period two Phase I electronic circuits failed after 40 months of operation. In both circuits the failure mode was identical in that the output transistor developed an open emitter. Two preproduction nuclear batteries were assembled using essentially the materials and procedures presently intended for pilot production pacers. The performance of both units was significantly better than predicted. One of these units was placed on long term fatigue vibration testing. Recommendations were formulated and transmitted to the AEC on the fuel form to be used for the remaining heat sources required. Information and test data are presented on long term vibration testing, leak testing, elevated temperature testing of RPCP capsule with Pu metal fuel, life testing of experimental and prototype models, systems fabrication, and safety analyses. (L.C.L.)

57658 (ORNL-4723) ORNL ISOTOPIC POWER FUELS QUARTERLY REPORT FOR PERIOD ENDING JUNE 30, 1971. Lamb, Eugene (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 32p. Dep. NTIS.

Procedures have been developed with stand-in materials for fabricating cermets of varying fuel fractions which are permeable to helium and of high strength. These cermets are blends of metal and ceramic powders and can be produced by either hot-pressing or cold-pressing followed by sintering. Gadolinium is the stand-in for curium in the initial phase of process development for sized particles to be used in forming curium cermets. Rexyn 102H and Stratobed-84 ion exchange resins are being used in the study. Variables affecting density are being investigated to aid in obtaining a consistent high density. The most dense product was produced by loading the Gd_2O_3 onto Rexyn 102H. ORNL will fabricate the fuel pellets to be used in an accelerated $^{238}PuO_2$ fuel aging study. All parts of the CVD apparatus have been fabricated and are being tested. Experiments are being performed to determine phases present in $Cm_2O_3-PuO_2$ mixtures with Cm/Pu ratios of 0.03, 0.06, and 0.10. In order to eliminate or minimize pellet machining for this study, a trial hot-pressing with simulant was carried out in Al_2O_3-lined graphite dies and punches. Although densities of only 70% were obtained due to liner cracking, microprobe analysis revealed no diffusion of aluminum into the cermet. A miniaturized CVD coater system was designed and fabricated for molybdenum coating 5-g batches of $^{238}PuO_2$ and $^{242}Cm_2O_3-^{238}PuO_2$ powder. The CVD tungsten capsule was under test for 85 days at 1650°C when failure occurred. The characterization of Pt–Rh–W alloys is continuing. The effect of variations in the rhodium and tungsten contents have been investigated in order to determine the permissible limits. Only small changes in properties were obtained on alloys containing from 26 to 30% Rh and from 6 to 10% W. The compatibility of Pt–Rh–W with molybdenum and tungsten has been evaluated. An advanced version of this alloy containing small quantities of hafnium and titanium has been fabricated and shown to have a somewhat higher recrystallization temperature and slower grain growth rate which should permit its use to somewhat higher temperatures. Testing of tantalum alloys exposed to partial pressures of oxygen showed that Ta–10% W can dissolve as much as 1100 ppM oxygen without severe embrittlement while T-111 can only take something less than 750 ppM. However, a reentry heat pulse can ductilize T-111 containing up to 3000 ppM oxygen but will not help Ta-10% W. Catastrophic oxidation of T-111 in both pure oxygen and air has been discovered. After an incubation period of 2.5 hr at 800°C, T-111 has been observed to burn to powder. (auth)

57659 ISOTOPIC METHOD FOR DETERMINING THE EFFICIENCY OF EQUIPMENT FOR AGGLOMERATE PRODUCTION. Swigon, K.; Michalik, J. (Inst. fuer Kernforschung, Swierk, Poland). Isotopenpraxis; 7: No. 5, 167-71(May 1971). (In German).

The mixing efficiency of blast sintering plants for producing iron agglomerate was investigated using ^{140}La as a radiotracer. The method of labelling feed material is described. (tr-auth)

57660 STUDY OF THE COMPOSITION OF OXIDE COATINGS USING RADIOISOTOPES. Knyazeva, I. M.; Vasil'ev, V. P. Izv. Akad. Nauk SSSR, Ser. Fiz.; 35: No. 5, 1031-4(May 1971). (In Russian).

A doubly labeled oxide coating on the cathode of a lamp was employed to measure losses during lamp operation. A ternary Ba, Sr, Ca carbonate mixture containing ^{133}Ba and ^{45}Ca initially formed the cathode coating which subsequently was degassed in a vacuum and dissociated to the respective oxides at an elevated temperature. The lamp was then opened and the cathode sectioned by a microtome into 10-μ layers for making radioassays. The ratio of Ba/Ca for a given section of oxide coating was determined as a function of the depth of the layer and also as a function of the time of operation of the cathode. It was found that a large Ba loss occurred during thermal dissociation and activation of the cathode. The emission characteristics and service life of the oxide coating depend upon the volatilization processes of the Ba component. (K.S.W.)

57661 ^{252}Cf NEUTRON SOURCE. Nagy, Arpad. Atomtech. Tajek.; 13: No. 8, 492-4(Dec 1970). (In Hungarian).

The ^{252}Cf source which has become available only recently presents many advantages over conventional neutron sources. It is a high-intensity compact system which does not require target material, thereby reducing the fabrication cost. A 10^9 n/sec source fabricated on a large scale was estimated to cost about $250.00 (without packaging and transportation). In the design of sources, the amount of helium generated by the (n,α) reaction must be taken into account when calculating the volume to be incapsulated. A 5×10^{10} n/sec $^{242}Cm-Be$ source generates 470 cm^3 of helium, while the ^{252}Cf source generates only 2 cm^3. The neutron spectrum of ^{252}Cf is similar to the fission spectrum of uranium. The theoretically highest thermal or fast flux to be produced by this type of source is estimated at 10^{12} n/cm^2 sec which is close to that of a 0.1 MW reactor. The neutron spectrum can be efficiently thermalized. (TTT)

57662 INVESTIGATION OF THE EROSION OF HIGH-PRESSURE [BOILER] FITTINGS BY THE USE OF RADIOISOTOPES. Vlasov, P. V. Teploenergetika; No. 12, 47-50(Dec 1970). (In Russian).

A method is described for investigating the erosion of the hard-facing of high-pressure boiler fittings using radioactive isotopes. Hard-facings of stainless steel 1Kh18N9T and Co stellite on low-C steel St. 2 were investigated using ^{50}Cr and ^{60}Co. (Metals Abstr.)

57663 SOME USES OF RADIOACTIVE ISOTOPES IN MEASUREMENTS ON TURBINES. Noltingk, B. E.; O'Neill, P. C. (Central Electricity Research Lab., Surrey, Eng.). J. Brit. Nucl. Energy Soc.; 10: 49-54(Jan 1971).

Two measurement techniques used on large steam turbines are described. In both, radioactive isotopes are used and both have the advantage that only robust, temperature-resistant components are placed inside the turbine. In one technique, relative movement between two parts under thermal expansion is measured by arranging that the degree of overlap between two slots is varied, thus varying the radiation escaping from a partially shielded source. In the other, the progress of blade erosion is monitored by observing the activity of a button mounted at an appropriate point. (auth)

57664 SPECIFICATION FOR GAMMA RADIOGRAPHY EXPOSURE CONTAINERS FOR INDUSTRIAL PURPOSES, AND THEIR SOURCE HOLDERS. British Standard 4097 1966. London; British Standards Institution (1966). 17p. Available from American National Standards Institute, New York.

A standard prescribing requirements relating to shielding containers for sealed gamma sources for use in radiography is presented. (W.H.K.)

57665 SPECIFICATION FOR GAMMA-RADIOGRAPHY SEALED SOURCES. British Standard 3513 1962. London; British Standards Institution (1962). 15p. Available from American National Standards Institute, New York.

A standard prescribing requirements relating to the supply of a range of sealed gamma sources for use in radiography is presented. The standard covers sources of activity up to approximately 100 curies for cobalt-60 or 300 curies for cesium-137 or iridium-192. (W.H.K.)

57666 STATE OF THE FUEL CYCLE INDUSTRY IN THE FEDERAL REPUBLIC OF GERMANY. Wirths, G. (NUKEM GmbH, Wolfgang, Ger.). Atomwirt., Atomtech.; 16: No. 8-9, 455-61(Aug-Sep 1971). (In German).

In the FRG, the fuel cycle situation is reportedly characterized by too small a market and too large an excess capacity, especially for the supply of natural uranium for the production of UF_6 and for reprocessing of spent fuel elements. Only in the area of hydrogen isotopes is economical production possible on a national scale. Pilot plants exist for plutonium manufacture and for the production of uranium-thorium fuel elements for high-temperature reactors. In the field of uranium enrichment, efforts include participation in the West-European gas centrifuge project and, on a national scale, development of a nozzle separation method. (tr-auth)

57667 MASS FLOW RATE MEASURING UTILIZING THE SCATTERING CROSS-SECTION OF A MATERIAL FOR FAST NEUTRONS. Hahn, Linus K. (to Industrial Nucleonics Corp.). U. S. Patent 3,577,158. 4 May 1971. Filed 7 Jan 1969.

Measuring the mass flow rate of a fluid having a high scattering cross section for fast high-energy neutrons by irradiating the material with such neutrons which are slowed to lower energy thermal neutrons and detecting the thermal neutrons downstream is described. For a more accurate determination of the mass flow rate, a second thermal neutron detector downstream has its output compared to the first detector output. Further, a gamma source and detector is employed to derive the density of the material and to obtain the velocity thereof by division of the mass flow by the density. (Official Gazette)

57668 α-RAY HEAT SOURCE, SUITABLE FOR USE IN A CARDIAC PACEMAKER. Barthelemy, Pierre; Boucher, Rene (to Commissariat a l'Energie Atomique). U. S. Patent 3,600,586. 17 Aug 1971. Priority date 9 Nov 1967, France. Filed 5 Nov 1968.

The heat source comprises a leak-tight container and a body of α-emitting material in the container. The material is an alloy of ^{238}Pu and of Sc, Ce, In, Ga, or Am in such proportions that the alloy is in δ phase. The container consists of an inner sheath of tantalum or tungsten and of an outer sheath of platinum. (Official Gazette)

57669 EXPERIMENTAL EVALUATION OF A RADIOISOTOPE-POWERED CARDIAC PACEMAKER. Morrow, A. G.; Levitsky, S.; Frommer, P. L.; (and others) (National Heart and Lung Inst., Bethesda, Md.). J. Thorac. Cardiovasc. Surg.; 60: 836-41(Dec 1970).

A radioisotope-powered pacemaker developed by the USAEC is undergoing studies in animals. The unit has a potential operating life of 11 to 20 years. The ^{238}Pu fuel serves as a heat source for direct thermoelectric conversion. Over 200 μW are available to the pacemaker circuit. The fuel is triply encapsulated and provided with thermal and radiation shields; there is insignificant heat and radioactivity externally. The evacuated, hermetically-sealed titanium case is the anode; the unipolar stimulating electrode (cathode) is connected via a ceramic-to-metal feedthrough. The unit weighs 100 g and is comparable in size to conventional pacemakers. Seven prototype units have been implanted in dogs for periods of up to 10 months. There have been no changes in rate or in the amplitude and configuration of the stimulus artifact. Pacing has been maintained continuously, except in 1 animal in which brief interruption apparently resulted not from battery failure but from a defective electronic component. Continuing studies are directed to the development of manufacturing methods which will permit the production of these power sources in quantity at acceptable cost and at the evaluation of these units. (auth)

57670 STUDY OF EFFECTIVE NONSYMMETRIC MULTICOMPONENT ISOTOPE SEPARATION CASCADES. Kolokol'tsov, N. A.; Sulaberidze, G. A. At. Energ. (USSR); 31: No. 3, 223-5 (Sep 1971). (In Russian).

A theory of optimal multicomponent nonsymmetric separation cascades is developed. It is shown that the maximum of effectiveness corresponds to the minimum of the function of $[1/\epsilon^2\theta(1-\theta)]$ where θ is the cut and ϵ is the coefficient of separation of a pair of isotopes with a unit mass difference. It is assumed that this condition obtained only for one specific class of multicomponent cascades but may be applied to all multicomponent cascades. (auth)

57671 ELECTRICAL POWER SYSTEMS FOR SPACE: ACHIEVEMENTS AND ISSUES. Miller, P. Rex (National Aeronautics and Space Administration, Washington, D. C.). Astronaut. Aeronaut.; 9: No. 8, 22-30(Aug 1971).

The development of electric power systems for space use from 1958 to 1971 is reviewed. Solar, radioisotope-fueled, and reactor systems are discussed. It is suggested that the development of radioisotope and reactor systems for powers in the tens of kilowatts should be encouraged, that a reactor power system for manned earth-orbiting missions can be achieved, and that these developments in space power technology will have spin-off benefits for terrestrial applications. (L.C.L.)

57672 RADIOAKTIVNYE IZOTOPY NA ZHELEZNODOROZHNOM TRANSPORTE. (Radioactive Isotopes in Railway Transportation). Toropchinov, A. N.; Tikhonov, G. M.; Kuznetsov, L. F. Moscow; Atomizdat (1971). 160p.

Radioisotopes are used in the railway operating industry for controlling wear of track parts, evaluating lubrication performance, measuring corrosion, etc. The equipment and methods associated with the use of radioisotopes are discussed. Technical-economic factors in the application of radioisotopes are analyzed, including capital investment, usable lifetime, and net costs. Safety features which are dictated by the use of radioactive sources are summarized, including shielding technology, dosimetry, and radiometric apparatus. 114 references. (K.S.W.)

57673 APPLICATION OF β-RADIATION EXCITATION OF X RAYS FOR THE INVESTIGATION OF DIFFUSION IN SOLIDS. Radwan, M.; Lutze-Birk, A. (Inst. fuer Kernforschung, Swierk, Poland). Int. J. Appl. Radiat. Isotop.; 22: No. 9, 561-5(Sep 1971). (In German).

It has been suggested that diffusion investigation could be carried out by layer analysis based on the measurement of x rays formed in the β-x process. There are two such methods; the measurement of k x-rays characteristic for a given element and the measurement of the high-energy content of the bremsstrahlung radiation spectrum. The second method was investigated using the diffusion of bismuth in copper. The method can be applied to all β-emitting radionuclides that diffuse in media of sufficiently high atomic number. (UK)

57674 APPLICATION OF THE TRACER METHOD IN INVESTIGATIONS OF EVAPORATION PHENOMENA IN POWER BOILERS. Lebecka, Jolanta; Lewczuk, Jacek; Wareda, Eugeniusz (Measurement and Testing Establishment Energoponiar, Gliwice, Poland). Nukleonika; 16: No. 3-4, 158-68(1971).

A method of measuring the degree of dryness of wet steam in water-wall tubes of power boilers is reported. For these investigations the boiler water was labeled with ^{186}Re. Measurements were made on a standard PK-230 boiler. The measurement principles and practice, and the method of interpreting the results are presented together with a brief description of apparatus and radiological protection used. The measurement error is estimated. The measurements of steam dryness were conducted alongside thermal and chemical measurements providing data on the evaporation process in the boiler tubes. Conclusions are drawn as to the scope of application of the method described. (auth)

57675 EXTENSIVE ENRICHMENT OF STABLE OXYGEN ISOTOPES BY COUNTERCURRENT DISTILLATION OF HEAVY WATER. Staschewski, Dieter (Kernforschungszentrum, Karlsruhe, Ger.). Chem.-Ing.-Tech.; 43: No. 14, 810-16(Jul 1971). (In German).

The construction and mode of operation of a distillation plant that permits isolation of pure oxygen isotopes starting from heavy water and using the same substance as a working medium are described. The process engineering problem of coupling a large number of individual columns was solved satisfactorily for the plant under consideration. Extraction rates for the isotopes ^{18}O, ^{17}O, and tritium were determined for previously enriched feed water. Time-based and local variations in the concentration profiles prevailing in the initial stage and in the ^{18}O main stage were followed quantitatively. (auth)

57676 SPECTRA AND CONVERSION FACTORS OF NEUTRON CALIBRATION SOURCES. Burger, G.; Eckl, W.; Gredel, H. (Institut fuer Strahlenforschung, Neuherberg, Ger.). pp 467-75 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The absolute output and spectra down to E_n = 700 keV have been measured for several standard neutron sources (AmBe, PuBe, AmF, AmB, ^{252}Cf). Spectral measurements were performed with organic scintillators. The principal features of the experimental technique and the method of data analysis are discussed. The measured spectra are compared with theoretical ones, the dose-fluence conversion factors are calculated and changes in these for different

XUM

assumptions of the unknown low energy neutron spectrum are estimated. For some of the sources, leakage spectra from water moderators of varying sizes are calculated by a Monte Carlo code; the results are compared with measured leakage spectra and the corresponding conversion factors evaluated. The values for the unshielded sources decrease to about 70% when the sources are put into the center of a 12 in moderator. (auth)

57677 METHOD OF INVESTIGATING REFRACTORY WEAR IN METALLURGICAL FURNACES WITH RADIOACTIVE ISOTOPES. Skrebtsov, A. M. (Zhdanov Metallurgical Inst., USSR). Refractories (USSR) (Engl. Transl.); No. 9-10, 664-6(Sep-Oct 1970).

Translated from Ogneupory; No. 10, 52-4(Oct 1970).

Results of a study of lining wear in metallurgical furnaces showed that the possibility of diffusion of the isotope into the refractory structures must be considered. To reduce the radioactive-indicator diffusion into the refractory and improve the method of investigation, it is recommended that where possible, isotopes of heavy elements be used, and that ampules be used for eliminating or reducing the diffusion of the indicator into the refractory. (auth)

Materials Testing

Refer also to abstracts 57663, 57677, 57889, 58209, 58215, 58219, 58396, 59640, and 60142.

57678 (INR–1204) RADIOGRAPHICAL CONTROL OF THICKWALLED WELDS AND CASTINGS BY USING OF BETATRON. Janiczek, J.; Kielsznia, R.; Wolski, M. (Institute of Nuclear Research, Warsaw (Poland)). 1970. 77p. (In Polish). Dep. NTIS (U. S. Sales Only).

The operating principles of betatrons are given and the problem of using betatrons for radiographic investigations is discussed. Experiments were performed using the Nuclear Research Institute betatron, and conclusions were formulated concerning the range of application of commercially available radiographic films to industrial radiographic control using betatrons. Some types of betatrons and betatron laboratories are described. (auth)

57679 (LB/G–2986) UNDERWATER NEUTRON RADIOGRAPHY, SURVEILLANCE OF ACTIVE IN-PILE TESTS. FIRST RESULTS WITH COLD-NEUTRON RADIOGRAPHY. Perves, J. P. Translated by R. G. P. Towndrow (Atomic Energy Research Establishment, Harwell, Eng.), from Sixth International Conference on Nondestructive Testing, Hanover, June 1st–5th 1970. 17p. (CONF-700613–4). Dep. NTIS (U. S. Sales Only).

The development of equipment and methods in France for neutron radiography of radioactive objects, particularly for underwater radiography of irradiated material in pool-type reactors, is described, and research studies with a reactor beam and with cold-neutron radiography are discussed. (L.C.L.)

57680 (ORNL-TM–3561) REMOTE INSPECTION OF WELDED JOINTS. McClung, R. W. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 16p. Dep. NTIS.

Maintenance and repair of reactor components by remote welding will require development of adequate nondestructive examination techniques to assure the integrity of the weld. High temperature and radiation levels will require remote inspections and add to the complexity of the performance. Recommended developments include improved closed-circuit television for visual examination, evaluation of new high-temperature penetrants, study of neutron radiography, improved transducers for ultrasonics, and application of acoustic emission and eddy currents. Sophisticated mechanical positioning, manipulation, and scanning equipment will be required for most of the techniques. (auth)

57681 SIMPLIFIED METHOD OF ANALYTICAL DETERMINING THE COEFFICIENT OF INCREASE FOR GAMMA RADIATION. Czarnecki, J.; Kowalik, S. (Military Tech. Academy, Warsaw). Biul. Wojsk. Akad. Tech.; 15: 139-50(1966). (In Polish).

There is a need for an effective method for determining the build-up factors for the usual measuring geometry for isotopes used in industry. An attempt to determine these factors was made experimentally. A ^{60}Co radiation source was used in an iron-shielded container. Geiger Mueller counters were used. On the basis of the absorption curves obtained by the measurements, a series of generalized formulas was derived defining the absorption coefficient as a function of such parameters such as the collimation, coefficient of the beam of gamma radiation, distance from the source, and distance of the detector from the absorbing layer. A theoretical generalization, worked out on the basis of experimental measurements, provides grounds for making an extrapolation of measurements and determining the permissible limits for changes of the parameters. The results of calculations are presented in a form of tables and diagrams. They provide the basis for determining the real absorption coefficient of the gamma radiation. (NSA of Poland)

57682 STANDARD METHOD FOR CONTROLLING QUALITY OF RADIOGRAPHIC TESTING. ASTM E142-68. Philadelphia: American Society for Testing and Materials (1968). 8p. Available from American Society for Testing and Materials, Philadelphia.

Standards are presented for controlling the reliability or quality of radiographic images produced during the radiographic inspection of materials. These standards cover the technique used, the equipment and film material used, safety, and the recording of data on the method and results. The number of areas or parts to be radiographed and the acceptance standard to be applied shall be specified. The quality level required for radiography shall be at least 2 percent (2-2T), unless a higher or lower quality is agreed upon by the purchaser and the supplier. (L.C.L.)

57683 STANDARD REFERENCE RADIOGRAPHS FOR STEEL WELDS. ASTM E99-63. Philadelphia: American Society for Testing and Materials (1963). 2p. Available from American Society for Testing and Materials, Philadelphia.

A collection of reference radiographs is presented which covers types and degrees of discontinuities occurring in steel welds that are detectable by radiographic methods. The reference radiographs are in the form of mounted transparencies and are intended to serve as a guide for radiographic interpretation. No attempt was made to establish limits of acceptability for any discontinuity. However, where applicable and upon agreement of all interested parties, they may be used in production inspection to evaluate weld soundness as provided for in product specifications. (auth)

57684 STANDARD REFERENCE RADIOGRAPHS FOR HEAVY-WALLED ($4\frac{1}{2}$ TO 12-IN.) STEEL CASTINGS. ASTM E280-68. Philadelphia: American Society for Testing and Materials (1968). 3p. Available from American Society for Testing and Materials, Philadelphia.

Reference radiographs are presented which are reproductions of original radiographs and are supplied as a means of establishing the categories and severity levels of discontinuities in steel castings that may be revealed by radiographic examination. They may be used in accordance with contractual specifications. Radiographs for evaluation are to be compared with these reference radiographs for classification on the basis of the category and severity level of the discontinuity. These reference radiographs are applicable to nominal section thicknesses of $4\frac{1}{2}$ to 12 in. (114 to 305 mm). (auth)

57685 STANDARD METHOD FOR ULTRASONIC CONTACT INSPECTION OF WELDMENTS. ASTM E164-65. Philadelphia: American Society for Testing and Materials (1965). 6p. Available from American Society for Testing and Materials, Philadelphia.

A procedure for ultrasonically testing and inspecting welds by the reflection method using pulsed waves introduced by direct contact of the searching unit with the weldment is specified. The procedure is basically a manual method for thicknesses over $\frac{3}{16}$ in. (5 mm). Specific variations for thin materials, automatic searching, and through transmission methods are not covered in detail, but where adaptable, the procedure may be used with these variations. The test is conducted using angle projection of the ultrasonic beam by surface contact, except where indicated otherwise in the method. In special cases, pulsed longitudinal waves can be used as described in the Recommended Practice for Ultrasonic Testing by the Reflection Method, Using Pulsed Longitudinal Waves Induced by Direct Contact (ASTM Designation: E 114). (auth)

57686 STANDARD METHOD FOR ULTRASONIC INSPECTION OF METAL PIPE AND TUBING FOR LONGITUDINAL DISCONTINUITIES. ASTM E213-68. Philadelphia: American Society for Testing and Materials (1968). 4p. Available from American Society for Testing and Materials, Philadelphia.

A method is described for detecting longitudinal discontinuities in metal pipe and tubing using pulse-reflection ultrasonic contact or immersion techniques. It is intended to be used for tubular products having outside diameters from approximately $\frac{1}{2}$ to 6 in. These techniques have been used for smaller and larger sizes, however, and may be specified upon contractural agreement by the purchaser and the producer. The characteristic oblique entry of sound into the tube wall and the circumferential direction of the sound path are illustrated. (auth)

57687 STANDARD REFERENCE RADIOGRAPHS FOR STEEL FUSION WELDS. ASTM E390-69. Philadelphia: American Society for Testing and Materials (1969). 4p. Available from American Society for Testing and Materials, Philadelphia.

Reference radiographs are presented which may be used to establish the types and severity levels of discontinuities that are revealed by radiographic examination. They may be used with contractual specifications. The three volumes of reference radiographs are based on seven nominal weld thicknesses and are applicable to seven thickness ranges up to 8 in. Each volume contains illustrations of representative graded and ungraded discontinuities. The discontinuity types and severities illustrated for each thickness of base material are listed. Each of the graded discontinuity types has five severity levels, 1 through 5 in order of increasing severity. The ungraded discontinuities are included for informational purposes. (auth)

57688 EQUIPMENT FOR THE X-RADIOGRAPHY OF RADIOACTIVE OBJECTS. J. Inst. Eng., Aust.; 42: 8(Jan-Feb 1970).

Equipment that will permit the x-radiography of many radioactive objects is described. The design aim was to reduce the intensity of the nuclear radiation without reducing the x-radiation intensity at the film, so that a satisfactory x-ray image may be formed. The following techniques were used: separation of the object from the film; shielding the film with a dense material except during x-ray exposure; use of a powerful x-ray source; and collimation between object and film. With the source on the axis of the radially slit rotating collimator, the x-rays from the source pass fully through all slits. However, the radiation from the object only reaches the film from those points on the object, and hence the object radiation at the film is reduced. (auth)

57689 RADIOGRAPHY APPLIED TO DETERMINING DYNAMIC CONDITIONS INSIDE AERO GAS TURBINES. Pullen, D. A. W. (Atomic Energy Research Establishment, Harwell, Eng.). Brit. J. Non-Destruct. Test.; 13: No. 2, 42-5(Mar 1971).

Two methods of radiography are described which were developed in collaboration with Rolls-Royce Ltd., Bristol Engine Division. The first method uses gamma radiography and is relatively inexpensive in yielding data on steady-state conditions on smaller engines. The second method uses an 8-MeV linear accelerator with very high output, (Vickers Super X) and yielded valuable data with short exposure times (4 to 5 seconds) through sections of 6 in. to 8 in. steel equivalent on the Olympus 593 for Concorde. Conditions approaching transients were successfully recorded. (auth) (UK)

57690 METAL INTENSIFYING SCREENS FOR RADIOGRAPHY. Ratcliffe, B. J. (Royal Armament Research and Development Establishment, Fort Halstead, Eng.). Brit. J. Non-Destruct. Test.; 13: 55-9(Mar 1971).

An investigation was carried out on the resolution and intensification factor of different metal screen combinations for high-energy radiography. It was found that with 5.5-MeV x-rays to obtain the best quality radiographs of fine detail, such as cracks, copper screens should be used with a front screen thickness of 0.06″ and with a very thin backscreen. A thin backscreen of 0.002″ is necessary to prevent spurious images from the backing felt or the packing cardboard in the cassette. As a compromise between thickness and convenience for handling, a copper back screen thickness of 0.010″ is suggested. The use of tungsten or silver screens is discussed but dismissed on cost considerations. It was shown that with ^{60}Co γ rays copper intensifying screens (0.020 to 0.080″ front, 0.010 to 0.040″ back) produced radiographs which had better resolution of detail than any combination of lead screens: the exposure-time needed to be double that required for lead screens. Metal intensifying screens for use with 1-MeV x-rays should be lead to obtain images of fine detail. The front lead screen should have a thickness of 0.06″ and the back lead screen should be approx. 0.05″ thick. Although screens of appropriate thickness of copper, tungsten and tantalum will produce almost equally good radiographs, there is little point in using any material except lead, as longer exposures will be necessary to obtain the same film densities. Also lead screens have the advantage of making it easier to maintain close contact with the film emulsion. (UK)

57691 POLAROID POSITIVE FILM IN NEUTRON RADIOGRAPHY. Hawkesworth, M. R. (Univ. of Birmingham, Eng.). J. Phys., E (London); 4: 400-1(May 1971).

Observations are presented of the density-exposure and reciprocity law failure characteristics of Polaroid Type 57 and Type 52 film when used in conjunction with NE421 and NE905 thermal neutron intensifying screens. The NE421–Type 57 combination proved to be the fastest radiographically and also has extremely good reciprocity failure characteristics, which makes it most useful for radiography with low intensity neutron beams. (auth)

57692 METHOD OF NONDESTRUCTIVE TESTING BY EDDY CURRENTS OF ELECTRICITY-CONDUCTING TUBES AND CORRESPONDING APPARATUS. Dufayet, Jean-Pierre; Dujardin, Roger (to Commissariat a l'Energie Atomique). French Patent 1,470,386. 3 Aug 1970. Filed 17 Oct 1968. 2nd Addition 95,394. (In French).

This addition to the main patent concerns a nondestructive method of testing electrically conducting tubes (in particular nonferromagnetic tubes and nuclear fuel pins). It is distinguished by the following points: the Hartley oscillator is electrically coupled to an alternating voltage generator and a given type of defect is detected by the resulting changes, according to the frequency of the voltage V supplied by the generator, in the grid voltage V_g of the oscillator triode and/or the voltage V supplied by the generator to the oscillator. The frequency of the alternating voltage supplied by the generator is varied cyclically within a frequency band extending on either side of the natural frequency of the oscillator and the displacements and deformations of the curve representing the variation against the frequency of the grid voltage V_g, and/or of the curve representing the variation against the frequency of the voltage V, are analyzed. A frequency is chosen in a zone where the sensitivity to the type of defect investigated is as high as possible and the sensitivity to other types of defect as low as possible, and the variations in the grid voltage V_g and/or in the voltage V are followed at this frequency. (auth) (France)

57693 TECHNIQUE FOR HOT CELL AUTORADIOGRAPHY. Jeffries, D. D.; Waldschmidt, L. A. (Los Alamos Scientific Lab., N. Mex.). pp 83-6 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

A method is described for obtaining high quality alpha and beta-gamma autoradiographs from irradiated fast reactor fuel specimens. The method, which was developed for remote application in a hot cell, permits a high processing rate. Also described is the pneumatic system for assuring positive contact between the specimen and the films being used. (auth)

57694 STANDARD REFERENCE RADIOGRAPHS FOR STEEL CASTINGS UP TO 2 IN. (51MM) IN THICKNESS. ASTM E71-71. Philadelphia; American Society for Testing and Materials (1971). 2p. Available from American Society for Testing and Materials, Philadelphia.

Reference radiographs are presented which illustrate various types and degrees of discontinuities occurring in steel castings which have section thicknesses of up to 2 in. They are intended to provide the following: a guide enabling recognition of discontinuities and their differentiation both as to type and severity level; example radiographic illustrations of discontinuities and a nomenclature for reference in acceptance standards, specifications, and drawings; and a source of reference radiographs from which purchasers and suppliers may, by mutual agreement, select particular radiographs to serve as standards representing minimum acceptability. At the same time, the standards so established may be unambiguously identified by alphabetic defect type designation and severity level. Two sets of reference radiographs are provided herein. One set, made with 220 kV x rays, is intended for the evaluation of radiographs made with relatively low energy radiation, (x rays up to 400 kV and iridium-192). The second set, made with a radium source, is applicable to radiographs made with high energy radiation (1 and 2 MeV x rays, betatron x rays and cobalt-60 gamma rays). In each of these two sets, there are 31 radiographs which illustrate 7 different types of discontinuities of various severity grades or classes as in Table 1. (auth)

57695 STANDARD SPECIFICATION FOR STRAIGHT-BEAM ULTRASONIC EXAMINATION OF PLAIN AND CLAD STEEL PLATES FOR SPECIAL APPLICATIONS ASTM A578-71. Philadelphia; American Society for Testing and Materials (1971). 5p. Available from American Society for Testing and Materials, Philadelphia.

The procedure and acceptance standards are specified for straight-beam, pulse-echo, ultrasonic examination of rolled carbon and alloy plain and clad steel plates $^3/_4$ in. thick and over, for special applications. The method will detect discontinuities parallel to the rolled surfaces. Two levels of acceptance standards are provided. Supplementary requirements are provided for examination of clad plate and for alternative procedures. (auth)

57696 EVALUATING THE EFFICIENCY OF RADIOGRAPHIC QUALITY CONTROL. Akopov, V. S. Sov. J. Nondestruc. Test. (Engl. Transl.); No. 5, 557-9(Sep-Oct 1969).

Translated from Defektoskopiya; No. 5, 56-9(Sep-Oct 1969).

A method is discussed for evaluating the efficiency of radiographic quality control of articles. A criterion is offered for evaluating the overall efficiency, which determines the economic result of raising the articles' quality per ruble expended for this purpose. Using this criterion, one can demonstrate the value of introducing various control methods. (auth)

57697 OPTIMAL TIME OF USING A RADIOISOTOPE SOURCE OF RADIATION IN NONDESTRUCTIVE TESTING. Sul'kin, A. G.; Akopov, V. S.; Komarova, Yu. P.; Borisov, A. E. Sov. J. Nondestruc. Test. (Engl. Transl.); No. 2, 215-18(Mar-Apr 1970).
Translated from Defektoskopiya; No. 2, 102-5(Mar-Apr 1970).

A method is proposed for determining the optimal lifetime for a radioisotope source in relation to the complex of technical/economical aspects of nondestructive testing and recommendations for industry are given. (auth)

57698 DEVELOPMENT OF A METHOD OF NEUTRON RADIOGRAPHY OF MIXED OXIDE FUELS USING RADIOGRAPHIC ANALOGS. Dahlke, Lutz W.; Robkin, Maurice (Univ. of Washington, Seattle). Nucl. Technol.; 12: No. 4, 407-18(Dec 1971).

A high-resolution neutron radiographic system was developed for radiographing mixed-oxide particle fuels. The method was tested without fuel using TiO_2, Eu_2O_3 and RhO_2 mixtures as analogues for the oxides of U, ^{239}Pu, and ^{240}Pu respectively. These analogues have microscopic cross-sections similar to the fuel isotopes. Two wt % PuO_2-UO_2 fuel rod radiographic analogues were built containing PuO_2 analogue particle dia distributions from 0 to 800 μ. These radiographic analogues were radiographed with resonant energy neutrons using the activation transfer neutron detection technique to examine both the homogeneity of the mixed-oxide and the imaging of the various diameter PuO_2 analogue particles. A divergent neutron collimator was designed to successfully complete this study. Also, an experiment was performed to determine the contrast sensitivity of neutron radiography for the radiographic discrimination between the analogue for $^{239}PuO_2$ and the analogue for $^{240}PuO_2$. (auth)

57699 MASKED EDDY CURRENT PROBE (3 Aug 1971) (Engineering Materials). (Los Alamos Scientific Lab., N. Mex.). (CAPE-2122).
6 drawings.

A masked probe used in eddy-current detection of small closely spaced circumferential cracks in the 0.006 in. coatings of Rover fuel elements is described. The operating frequency of 8 M Hz will not penetrate the 0.006 in. thick brass mask, therefore, the probe signal is affected only by the small amount of material close to the slits of the mask. The outside dia of the mask is 0.084 in. The coil is wound of 0.003 in. dia wire and shaped to conform to the 0.073 in. ID of the mask. Eddy currents flowing along the axis of the bore are primarily sensitive to circumferential cracks. The coil, which has 50 turns, gives reasonable amplitude signals at 8 M Hz driving frequency and is not overly sensitive to capacity changes due to probe and cable movement. The electronics include the oscillator, isolation resistor, rectifier and filter, high-pass filter, adjustable-gain amplifier, non-linear response amplifier, two converters, and a recorder. The oscillator is a 10 Hz to 10 M Hz laboratory sine-wave generator. The isolation resistor causes the probe to operate in an effective constant current mode. The rectifier and filter change the varying amplitude probe signals to a varying dc voltage. The high-pass filter, which has a gain of 20 and a cut-off frequency of 3 Hz, filters out variations of the coating conductivity due to the temperature profile of the furnace. The adjustable-gain amplifier allows compensation for variations in the sensitivity of different probes. The non-linear response amplifier enhances the effect of small crack signals. The output signals of these two amplifiers are fed to a strip-chart recorder where a permanent record of the basic data is made. (For details see TID-4100 Suppl. 66) (see also NSA 23: 50084 and 25: 21257) (F.S.)

57700 DETECTION OF DEFECTS IN BUTT WELDS WITH BETA RAYS. Blinova, O. P.; Kreindlin, I. I.; Mashinin, V. A.; Terskii, R. V. Sov. J. Nondestruc. Test. (Engl. Transl.); No. 4, 378-82(Jul-Aug 1969).
Translated from Defektoskopiya; No. 4, 15-23(Jul-Aug 1969).

The use of β particles for radiography of thin welded joints is considered. Tests are reported for steel 0.7 to 0.8 mm thick with argon arc welds. It is concluded that the method is workable. The difficulties are discussed. (auth)

57701 DEFECT DETECTION IN GAMMA-SCINTILLATION NONDESTRUCTIVE TESTING. Kol'chuzhkin, A. M.; Uchaikin, V. V. (Tomsk Polytechnical Inst., USSR). Sov. J. Nondestruc. Test. (Engl. Transl.); No. 1, 74-80(Jan-Feb 1969).
Translated from Defektoskopiya; No. 1, 86-94(Jan-Feb 1969).

The energy dependence of the signal-to-noise ratio was studied by the counting and current detection methods for monoenergetic sources and a collimated detector. Scattered radiation spectra calculated by the Monte Carlo method were used to estimate the effects of the scattered radiation on the appearance of defects. Detection of defects in the current mode was calculated for the case in which a continuous spectrum source is used. (auth)

57702 (BNWL-B-112) SUMMARY REPORT ON ANALYSIS OF THE SEMI-FLUID CONDITION IN THE PG-6 PHOSPHATE GLASS SOLIDS CONTAINER. McElroy, J. L.; Mendel, J. E.; Roberts, F. P. (Battelle Pacific Northwest Labs., Richland, Wash.). May 1971. Contract AT(45-1)-1830. 30p. Dep. NTIS.

An 8-in. stainless steel pot was filled with phosphate glass in May 1968, placed in water storage, then placed in a controlled water environment, and removed in January 1969 for core drilling. In the top core drill hole a semi-fluid region was located within the center of the pot. A second core drill near the pot mid-plane revealed only a slight amount of fluid present, and a core drill near the bottom revealed no fluid present. It was found that thermocouple wells failed after the unit had been placed in the environmental test. Water from the storage pot entered through the failed thermowells and a boiling-refluxing action occurred within the pot that severely leached and degraded a portion of the product. (M.C.G.)

57703 (DPSPU-71-124-4A) SAFETY SUMMARY REPORT: SPERT-III FUEL IN PADUCAH DEMONSTRATION CASK (PACKAGING OF RADIOACTIVE AND FISSILE MATERIALS). Final Report. Scaggs, R. A. (comp.) (Du Pont de Nemours (E. I.) and Co., Aiken, S. C. Savannah River Plant). Sep 1971. Contract AT(07-2)-1. 77p. Dep. NTIS.

Provisions for compliance with regulations concerning shipment of irradiated SPERT-III fuel from Idaho Falls, Idaho, to the Savannah River Plant, Aiken, South Carolina, in the Paducah Demonstration Cask which is shielded with depleted uranium are examined. The cask is 50.75 in. high inside and has an ID of 17 in. and an OD of 30 in. at the base of the fins which are 3 in. high. The wall consists of an inner stainless steel shell 0.25-in.-thick, 5.75 in. of laminated uranium, and an outer stainless steel shell 0.50-inch-thick. The cask with its fuel load weighs about 30,000 pounds. The shipments will include about 1556 fuel rods, containing UO_2 pellets with an active length of 38.3 in., and initial ^{235}U enrichment of 4.8%, and a SS cladding (0.466-in. OD by 0.020-in. thick). The total amount of UO_2 per rod is 910 grams. Aside from these rods, miscellaneous items, including smaller sound rods, failed rods, cut pieces, loose pellets, and powder having 3.1 to 10.6% enrichment and a total of not more than 2880 grams of ^{235}U, will also be shipped in stainless steel cans. (auth)

57704 (GULF-RT-A-10826) APPLICATION OF PHOTO-INDUCED REACTIONS TO NUCLEAR MATERIALS SAFEGUARDS PROBLEMS. Project Summary Report, July 1, 1970–June 30, 1971. Bramblett, R. L.; Costello, D. G.; Ginaven, R. O.; Gozani, T.; Hyde, A. T.; Naliboff, Y. D.; Rundquist, D. E.; Trimble, G. D. (Gulf Radiation Technology, San Diego, Calif.). 17 Sep 1971. Contract AT(04-3)-167. 151p. Dep. NTIS.

The research and development performed on techniques and application of nondestructive measurements of nuclear materials during the fiscal year July 1, 1970 to June 30, 1971 are described. During the fiscal year the Gulf Mobile Assay System (GAMAS) has been operated in the field under a wide variety of assay and weather conditions. Four locations have been visited in the states of California, Colorado, Missouri, and Idaho. The Idaho operation demonstrated the ability of GAMAS to provide assay equipment quickly when needed. GAMAS has been used to assay waste, scrap, and products of nuclear material containing low enrichment uranium, highly enriched uranium and plutonium. Sample containers ranging from quart to 55-gallon drums have been assayed. GAMAS operations at the field sites have clearly demonstrated the capability to accurately assay large containers with heterogeneous distributions of matrix and nuclear materials. It was shown that the majority of the nuclear waste generated at a nuclear facility can be assayed to an accuracy of ±15% or better, even in the large containers. Smaller containers with homogeneous quantities of nuclear material have been assayed to better than 1% under field operating conditions. Data acquisition and analysis methods have been described in conjunction with the Hewlett-Packard 2116B computer. The computer features completely automatic barrel scanning operation which is unique in the safeguards program. The Isotopic Source Assay System (ISAS), developed under the AEC Plant Instrumentation Program, is described. The ISAS, in conjunction with GAMAS, has demonstrated the applicability and versatility of this device as a nondestructive assay tool adaptable to many of the routine and nonroutine problems encountered in the nuclear industry. (auth)

57705 (MLM-1812) ATMX-500 RAIL CAR MODIFICATION. McDonald, E. P. (Mound Lab., Miamisburg, Ohio). 25 Aug 1971. Contract AT(33-1)-Gen-53. 21p. Dep. NTIS.

The development of a radioactive material container concept, the modification necessary to achieve a suitable container, and Mound Laboratory's experience in using this container are described. A modified ATMX-500 railroad car has been certified as meeting all applicable AEC and U. S. Department of Transportation (DOT) requirements and is currently being used under DOT Special Permit No. 5948. Particular emphasis is placed on the entire container concept since the present plans concerning the Salt Mine Repository in Lyons, Kansas, rely heavily on the use of these or ATMX-600 Series railroad cars. The report is intended to provide the basis for future modification of additional ATMX-500 cars to support the AEC plans for waste disposal. Procedural outlines, dimensional sketches and sequential photographs of the structural modifications are included to support this objective. Also included are the loading and shipping guidelines which were developed for effective utilization of these cars. (auth)

57706 (ORNL-TM-3545) CASK AND WASTE CONTAINER COOLING STUDIES. Holmes, J. M. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 22p. Dep. NTIS.

Digital simulation of an unsteady-state heat transfer system has been used to model the cooling of a cask containing cylinders of high-level radioactive waste solids prior to their removal from the cask at the National Radioactive Waste Repository in Lyons, Kansas. The recommended procedure involves, first, cooling the radiation shield of the cask with water (100 gpm) and, then, cooling the cask contents with steam. Dry steam (5000 lb/hr) is recommended for cooling of the cylinder walls to below 900°F in order to prevent excessive thermal shock to the metal. This would be followed by cooling with wet steam (5000 lb/hr, containing 40% moisture) which will reduce the average wall temperatures to less than 250°F. The procedure for cooling the radiation shield will require about 2 hr, while that for cooling the interior of the cask will require 5 hr. Air and helium were also considered for use in cooling the contents of the cask. (auth)

57707 IMPROVED PHOTOGRAPHIC LEAK TEST SYSTEM FOR SEALED SOURCES OF ^{226}Ra. Bedrosian, P. H.; Sensintaffar, E. L. (Public Health Service, Montgomery, Ala.). Amer. J. Roentgenol., Radium Ther. Nucl. Med.; 112: No. 4, 788-91(Aug 1971).

An improved radon photographic method is described which is as rapid as other radium leak test procedures, is more economical, and offers more safety to personnel than many of the other techniques. Testing a 50 mg radium source by the photographic method usually involves less than 5 mr exposure to the hands when one foot or longer handling tools are used in performing the test. The device is portable and thereby useful for field applications. It may be connected to storage safes and calibrated for testing sources while they remain in storage. Leak testing of large numbers of sources by this technique may be safely done on a daily, weekly, or longer basis. (auth)

57708 RADIOACTIVE-WASTE DISPOSAL INTO THE SEA. Safety Series No. 5 1961. Vienna; International Atomic Energy Agency (1961). 174p. (STI/PUB-14). Available from UNIPUB, Inc., New York.

The IAEA ad hoc panel on radioactive waste disposal into the sea made a preliminary study of the possible contamination effects of such waste disposal by considering the magnitude of radioactive waste problems, the nature of the marine environment, maximum permissible exposure to radiation from radioactive waste disposal into the marine environment, and control measures. Recommendations, based on these studies, are offered which could serve as a basis for international agreement to ensure that any disposal of radioactive waste into the sea involves no unacceptable degree of hazard to man. Nine appendixes of technical information related to sea-disposal of radioactive wastes are included. (L.C.L.)

57709 SAFE HANDLING OF RADIOISOTOPES. FIRST EDITION WITH REVISED APPENDIX I. Safety Series No. 1 1962. Vienna; International Atomic Energy Agency (1962). 119p. (STI/PUB-1)(Rev. 1)). Available from UNIPUB, Inc., New York.

A guide to the safe handling of radioisotopes is presented. It is hoped that it will prove helpful particularly to small-scale users who may not have direct access to other sources of information. (auth)

57710 HAZARDOUS MATERIALS REGULATIONS OF THE DEPARTMENT OF TRANSPORTATION INCLUDING SPECIFICATIONS FOR SHIPPING CONTAINERS. Tariff No. 23 1969. Washington, D. C.; Department of Transportation (1969). 394p. Available from R. M. Graziano, Agent, Washington, D. C.

Regulations of the US Dept. of Transportation related to the shipping of hazardous materials by rail or highway are presented. Information is included on: individual US carriers affected; rulemaking procedures of the Hazardous Materials Regulations Board; restrictions covering the acceptance and transportation of explosives and other dangerous articles; itemized list of hazardous materials and the labeling required for shipping of each; specific requirements for rail freight, rail express, and rail baggage service carriers and for motor vehicle transport within municipalities and on public highways; and specifications for shipping containers and tank cars. (L.C.L.)

57711 CODE OF PRACTICE FOR CONVEYANCE THROUGH PORTS OF RADIOACTIVE MATERIALS. London; Ministry of Transport (1966). 25p. Available from British Information Service, New York.

A guide for the safe handling of all radioactive materials including fissile materials in ports, docks, and harbors in the United Kingdom is presented. (auth)

57712 AMERICAN NATIONAL STANDARD GUIDE TO SAMPLING AIRBORNE RADIOACTIVE MATERIALS IN NUCLEAR FACILITIES. ANSI N13.1 1969. New York; American National Standards Institute, Inc. (1969). 39p. Available from American National Standards Institute, New York.

A standard is presented which sets forth the principles that apply in obtaining valid samples of airborne radioactive materials, and prescribes acceptable methods and materials for gas and particle sampling. The scope of the standard is limited to the collection of samples and does not embrace the measurement of the radioactive materials collected. The scope is further limited to guides for sampling airborne radioactive materials in installations where work with radioactive materials is conducted, with the primary emphasis on the need to protect the radiation worker and includes sampling effluent gases prior to or at the point of release to the atmosphere from the installation. Although the scope thus excludes certain sampling techniques, such as some of those used in environmental and free atmosphere sampling, the principles defined and most of the methods discussed are in most cases generally applicable. (auth)

57713 DANGEROUS GOODS BY FREIGHT TRAIN AND BY PASSENGER TRAIN OR SIMILAR SERVICE. LIST OF DANGEROUS GOODS AND CONDITIONS OF ACCEPTANCE. B.R. 22426 (Revised) 1966. London; British Railways Board (1966). 244p. Available from British Information Service, New York.

Regulations of the British Railways Board for marking, packaging, handling, and transporting dangerous goods carried on freight or passenger trains are presented. These goods are categorized as: explosives, gases, inflammable liquids, inflammable solids, oxidizing substances, organic peroxides, toxic substances, infectious substances, radioactive materials, corrosives, and miscellaneous dangerous substances. (L.C.L.)

57714 USA STANDARD GUIDE FOR ADMINISTRATIVE PRACTICES IN RADIATION MONITORING (A GUIDE FOR MANAGEMENT). USAS N13.2 1969. New York; United States of America Standards Institute (1969). 15p. Available from American National Standards Institute, New York.

This standard provides guidance for the administrative practices associated with the monitoring of ionizing radiation in and about installations where there is a potential for radiation exposure. It considers the management aspects of an effective radiation monitoring program. (auth)

57715 PHYSICAL INVENTORIES OF NUCLEAR MATERIALS. ANSI N15.3 1971. New York; American National Standards Institute (1971). 7p. Available from American National Standard Institute, New York.

This standard specifies the minimum frequency for physical inventories and the fundamental steps which nuclear facility management shall take to ensure adequate physical inventories of nuclear materials. (auth)

57716 RECORD AND REPORTING UNITS FOR NUCLEAR MATERIALS CONTROL. ANSI N15.2 1971. New York; American National Standards Institute (1971). 4p. Available from American National Standards Institute, New York

The nuclear materials to which this standard shall apply include:

special nuclear materials such as uranium enriched in the isotope U-235 (subsequently referred to as "enriched uranium"), uranium enriched in the isotope U-233 (subsequently referred to as "uranium-233"), plutonium, and plutonium-238. This category shall be used if the contained isotope ^{238}Pu is greater than 10% of the total Pu element weight. Source materials are defined as uranium depleted in the isotope ^{235}U below 0.711 weight percent (subsequently referred to as "depleted uranium"), normal uranium; thorium; and tritium. This standard applies to records and reports of a facility which may reasonably be expected to be contributing to internal and external accountability. (auth)

57717 GUIDE TO PRACTICE NUCLEAR MATERIAL CONTROL SYSTEMS FOR CONVERSION FACILITIES. ANSI N15.4 1970. New York; American National Standards Institute (1970). 12p. Available from American National Standards Institute, New York.

This standard establishes requirements for control of nuclear material in conversion facilities. The basic materials to be converted include "yellow cake" or similar crude uranium compounds, uranium or plutonium oxides or nitrate, or uranium hexafluoride. The products of a conversion process include uranium hexafluoride, uranium or plutonium metal, uranium or plutonium oxides (chiefly UO_2 or PuO_2 or mixtures of these), or uranium or plutonium carbides, nitrides, etc. (auth)

57718 PLUTONIUM METAL CRITICALITY MEASUREMENTS. Hunt, D. C.; Boss, M. R. (Dow Chemical Co., Golden, Colo.). J. Nucl. Energy; 25: No. 6, 241-51(Jun 1971).

The results of a series of critical mass measurements on alpha-phase plutonium metal (5.9 wt % ^{240}Pu) are reported. The assemblies investigated were spheres and hemispheres either unreflected or reflected by combinations of steel and oil. The spherical critical masses are deduced from measurements on asymmetric spherical assemblies while the hemispherical critical parameters are obtained directly. Forty-two critical masses were measured. A description of the measurement techniques and experimental apparatus is given. The methods of data analysis together with the uncertainties due to the effects of the experimental apparatus are presented. Calculational estimates of the critical masses of hemispherical assemblies are made using a modified KENO computer code. Spherical assembly of calculations are done with the DTF code. Both codes make use of the 16 group Hansen–Roach neutron cross-section sets. The results of the measured and calculated critical masses are reported in tabular form. A comparison of the results from this work and that of other investigators is presented. (auth) (UK)

57719 STORAGE OF RADIOACTIVE SUBSTANCES. Patane, Michelangelo; Van Damme, Jacques (to EURATOM). British Patent 1,225,951. 24 Mar 1971. Priority date 12 Jan 1968, Germany.

A method for handling and storing radioactive substances is described which is comprised of a multiplicity of upright tubes or sockets in a concrete block, the mouths of the sockets, which face upwardly, being all at the same level and each being provided with a closure plug or cover, and a cell above the tubes providing screening against β and γ radiation and equipped with remote-control manipulators characterized in that the cell is in the form of a bottomless box with a base area smaller than the area occupied by the mouths of the tubes and is movable on rails over the area so occupied. (L.C.L.)

57720 SHIELDED SHIPPING CONTAINER (2 Dec 1970) (Engineering Materials). (Los Alamos Scientific Lab., N. Mex.). (CAPE–2118).
7 drawings.

The design of a small cask for shipping up to 3 kg of fissile material such as whole or sectioned irradiated fast reactor fuel elements, associated hardware and components, and large quantities of other radioactive materials is presented. The cask meets the criteria for Fissile Class I shipments. Packaging consists of a steel encased right cylinder of depleted U that weighs ~2,000 lb. The cavity of the cask is too small to support criticality and an infinite array of containers are subcritical if loaded with any fissile materials. A drain with a fusible plug is provided. At a temperature of 100°F, contents of the container will be restricted to a maximum of 32 W thermal decay energy. The cask withstands 1475°F heat without melting. The worst damage condition resulting from a 30 ft free drop is plastic deformation of 1.41 in. on the outer edge of the container. The inner container is fabricated of 0.250 in. thick 304 stainless steel. (For details see TID-4100 Suppl. 66) (F.S.)

57721 (AECL-3989) GAMMA MONITOR FOR MEASURING ENVIRONMENTAL GAMMA DOSES AND DOSE RATES. Jones, A. R. (Atomic Energy of Canada Ltd., Chalk River (Ontario). Chalk River Nuclear Labs.). Aug 1971. 17p. Dep. NTIS (U. S. Sales Only). AECL $0.50.

A G–M monitor which permits estimation of gamma doses and dose rates at the low levels expected at the perimeters and surroundings of nuclear power stations and research laboratories. Dose rates are presented on a logarithmic scale 5 μrad/h to 5 mrad/h which can also be remotely monitored. Doses from 1 μrad to 10 rad are displayed on a register and can be measured over long periods (~1 year). The instrument is designed and calibrated to indicate the mean gonad dose absorbed by a population living in the vicinity. It can also be used for monitoring doses and dose rates to atomic energy workers in a low background (<6 mR/h). The monitor operates from line power, internal rechargeable batteries or solar batteries and is designed to operate in outdoor conditions of temperature and humidity. The design and performance of the monitor are described. An appendix gives circuit voltages, pulse heights and widths, and adjustments to aid in repair and manufacture. (auth)

57722 (CEA-R-4183) VERSATILE ANALOG DEVICE FOR IDENTIFYING CHARGED PARTICLES BY THEIR ENERGIES AND IONIZING POWERS. Harmanci, Ali Emre (Commissariat a l'Energie Atomique, Saclay (France). Centre d'Etudes Nucleaires). 1971. 175p. (In French). Dep. NTIS (U. S. Sales Only).

The various methods of identification previously used are discussed; particular attention is given to a $\Delta E-E$ telescope. The usual approximations of the Bethe–Livingstone equation are examined, and a more universal formula is given. It is shown that, when this formula is applied to the case of light particles (p, d, t, ^{3}He, α), identification over a wide energy range is possible. The equipment operates logarithmically by using analog operators. The identifier possesses certain special features, especially concerning the logarithmic convertors and the base-line restorers. High accuracy, speed, and a good performance at high counting rates were achieved. Experimental results confirm the performance of the equipment and the validity of the formulas used. A large number of particles corresponding to $Z \leq 8$ were identified. (111 references) (auth)

57723 (CONF-711002–, pp 82-5) HIGH-TEMPERATURE NEUTRON DOSIMETERS. Joyeux, J.; Van Audenhove, J. (European Atomic Energy Community, Geel (Belgium). Central Nuclear Measurements Bureau). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

In order to fulfill a need for high-temperature neutron flux measurements, preparation methods for Al_2O_3 + CoO (1% Co) and MgO + CoO (1% Co) activation detectors were developed, and compatibility with graphite-, Mo-, Al_2O_3- and MgO-contact materials up to 1500°C was investigated. (auth)

57724 (CONF-711002–, pp 86-90) PREPARATION OF NEUTRON DOSIMETERS FOR REACTORS. Box, W. D. (Oak Ridge National Lab., Tenn.). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

The standardization of activation detectors for in-core neutron flux monitoring is described. Size standardization and the preparation and use of ultrahigh purity vanadium as the encapsulating material are discussed, ^{10}B, ^{45}Sc, ^{232}Th, ^{235}U, ^{238}U, ^{237}Np, ^{238}Pu, ^{239}Pu, ^{240}Pu, and ^{241}Pu have been prepared. (W.H.K.)

57725 (KFKI-71-22) PROGRAM FOR THE DETERMINATION OF NEUTRON SPECTRA FROM ACTIVATION DATA. Fisher, A.; Turi, L. (Magyar Tudomanyos Akademia Kozponti Fizikai Kutato Intezete, Budapest). [nd]. 33p. (In Russian). Dep. NTIS (U. S. Sales Only).

A method for unfolding neutron spectra from activation data is described. The code RFSP is an advanced version of the well known SPECTRA code. The program determines the spectrum which satisfies the activation equations and minimizes a quantity characterizing the deviation from the reference spectrum. Compared to SPECTRA, a typical run by RFSP requires much less time. The algorithm of the method and input/output specifications of the code are given. (auth)

57726 (STI/PUB-269) ADVANCES IN PHYSICAL AND BIOLOGICAL RADIATION DETECTORS. Proceedings Series. Proceedings of a Symposium, Vienna, 23-27 November 1970. (International Atomic Energy Agency, Vienna (Austria)). 1971. 756p. (In several languages). (CONF-701112). IAEA $21.00.

Separate abstracts were prepared for 58 of the 61 papers presented. The remaining three papers were previously included in NSA. (W.H.K.)

For abstracts of individual papers see: 57362, 57676, 57767–57782, 57822, 57823, 57833–57861, 58012–58019, and 58126.

57727 NUCLEAR-PARTICLE TRACK DETECTION USING LIQUID–LIQUID PHASE SEPARATION: THE GLASS CHAMBER. Srinivasan, G. R.; Younger, S.; Macedo, P. B.; Litovitz, T. A. (Catholic Univ. of America, Washington, D. C.). Contracts AT(40-1)-2854; N00014-68-A-0506-02. Phys. Rev. Lett.; 27: No. 16, 1084-6(18 Oct 1971).

A new technique is described for the detection of charged-particle tracks in glasses. The energy stored along the particle tracks is used to initiate heterogeneous nucleation of the second liquid phase. Track registration results are presented for uranium fission fragments using a sodium-silicate glass. (auth)

57728 NEUTRON DETECTOR. Rozenblyum, N. D.; Mitel'man, M. G.; Panasyuk, I. S.; Erofeev, R. S. Russian Patent 263,755. 10 Nov 1970. Filed 20 Nov 1967. (In Russian).

The described self-powered neutron detector consists of an emitter and a collector separated by a dielectric. The neutron flux parameters can be measured using this detector. (J.F.P.)

57729 ACTIVATION DETECTOR. Biryukov, E. I.; Novikov, V. T.; Khramov, N. N.; Shimanskaya, N. S. Russian Patent 274,241. 24 Jun 1970. Filed 22 Jul 1966. (In Russian).

An activation detector for the measurement of thermal neutron currents is described. This detector eliminates danger of radiation and neutron field deformation. (J.F.P.)

57730 GERMANIUM BASED SEMICONDUCTOR DETECTORS. Silar, Josef. Radioisotopy; 11: No. 2, 229-93(1970). (In Czech).

The assortment of germanium based p-i-n detectors produced and commercially available by the Institute for Research, Production and Uses of Radioisotopes is presented in graphs and tables. The final parameters of present spectrometers with germanium based p-i-n detectors are discussed on the grounds of literature studies and experimental experience. The requirements as to material and technology in the production of some types of detectors and the evaluation apparatus are briefly summarized. (63 references) (auth)

57731 DISCRIMINATORY DEVELOPMENT OF ALPHA PARTICLE AND PROTON RECOIL TRACKS IN TYPE K EMULSION LAYERS. Sheptulenko, E. V.; Skibenko, K. P.; Rutkevich, N. Ya. (Physical-Technical Inst., Kharkov). Zh. Nauch. Prikl. Fotogr. Kinematogr.; 16: No. 3, 220-1(May-Jun 1971). (In Russian).

The possibility of discriminatory development of tracks of α-particles and recoil protons in type K emulsion in 400 μ layers which were irradiated with 14 MeV neutrons is studied. The photographic developer, p-hydroxyphenylglycine, was introduced into the fixed layers without having first affixed the layers to a support. Directions are given for preparing the developer and fixing solutions and treating the exposed film for optimum results. (K.S.W.)

57732 DEADTIME CORRECTION IN COUNTING RAPIDLY DECAYING SOURCES. Porges, K. G. A.; De Volpi, A. (Argonne National Lab., Ill.). Int. J. Appl. Radiat. Isotop.; 22: No. 10, 581-6(Oct 1971).

The classical problem of deadtime correction with a fixed paralysis is treated for rapid decay during the counting period. Convenient correction formulae are developed for computing the input rate from the count, as well as for the variance attached to such calculations, in the presence of a quasi-constant background. (auth) (UK)

57733 GEOMETRIC FACTORS FOR ANGULAR CORRELATION MEASUREMENTS WITH GAMMA RADIATION. Grosswendt, B.; Waibel, E. PTB Mitt.; 81: No. 3, 159-71(Jun 1971). (In German).

XUM

The influence of shielding and spectral thresholds on angular correlation attenuation factors was measured for a $3'' \times 3''$ NaI(Tl) detector in the energy range of the gamma-radiation from 0.51 to 6.1 MeV. Remarkable discrepancies were found comparing the experimental results with calculated attenuation factors, based on the total γ-attenuation coefficients. In addition some tables of calculated factors are completed. (auth)

57734 PROCEEDINGS OF THE SYMPOSIUM ON SEMICONDUCTOR DETECTORS FOR NUCLEAR RADIATION, HELD IN MUNICH, 11–13 MAY 1970. Munich; Technische Universitaet (1970). 346p. (CONF-700527).

Separate abstracts were prepared for 27 of the 28 papers in this symposium. The remaining one, on the use of an x-ray detector in activation analysis, has already appeared as NSA 24: 41655. (R.W.R.)

For abstracts of individual papers see: 57735–57748 and 57797–57809.

57735 ORIGIN OF LITHIUM PRECIPITATION CENTERS IN GERMANIUM. Schell, K. J. Philips Gloeilampenfabrieken, Eindhoven, Netherlands). pp 1-8 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Preferential etching of precipitated lithium in the n^+ layer of a Ge(Li) detector gives corroborative evidence that oxygen vacancy clusters act as nucleation centers. The same technique may also furnish information about the origin of such centers. (auth)

57736 PURIFICATION OF GERMANIUM CRYSTALS WITH A LEAD GETTER. Kegel, Gunter H. R. (Lowell Tech. Inst., Mass.). pp 35-43-43 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The possibility of using lead as a getter for the purification of solid germanium is examined. It is concluded that lead is an effective getter for copper, nickel, and silver. It is less useful for cobalt and iron. (auth)

57737 CURRENT PULSE SHAPES OF SEMICONDUCTOR DETECTORS, MEASURED WITH AN AVERAGING TECHNIQUE. Fretwurst, E.; Grube, R.; Haken, N.; Mueller-Roos, J.; Andersson-Lindstroem, G. (Univ., Hamburg). pp 44-61 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

A method for measuring the current pulse shapes of semiconductor detectors by using an averaging technique (sampling oscilloscope and signal averager) is described. The effects of bias voltage and direction of bombardment are investigated. The influence of radiation damage on the detector output at different bias voltages and temperatures is reported. (R.W.R.)

57738 DETERMINATION OF CARRIER-MOBILITY AND LIFETIME IN p–i–n DETECTORS FROM THE RESPONSE TO MODULATED LIGHT. Bernt, H.; Eichinger, P. (Institut fuer Technische Elektronik, Munich). pp 70-8 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The mobility and lifetime of charge carriers in p–i–n detectors were determined by a method based on the response of the detectors to sine-modulated light. This method is suitable for the determination of mobility and its dependence on the electric field strengths. Trapping and detrapping parameters may be found with relatively little experimental effort. The method is less suitable for an investigation of field profiles since the photocurrent is calculated from an integral over the field region. (R.W.R.)

57739 TEMPERATURE DEPENDENCE OF THE AVERAGE ENERGY PER ELECTRON–HOLE PAIR IN GERMANIUM. Stuck, R. (CRN, Strasbourg); Siffert, P.; Ricaud, C. pp 79-90 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Ge(Li) detectors irradiated with γ rays in the temperature range 20 to 120°K were used to determinate ϵ as a function of E_G, where ϵ is the average energy expended for the creation of an electron–hole pair and E_G is the bandgap energy. A linear relation was found. (R.W.R.)

57740 FULL-ENERGY PEAK EFFICIENCY CALIBRATION OF A WELL-TYPE Ge(Li) GAMMA-RAY DETECTOR. Verplanke, J. C.; Verheijke, M. L. (Philips Research Labs., Eindhoven, Netherlands). pp 91-100 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The full-energy peak efficiency of a 51-cm^3 Ge(Li) well-type detector was determined by means of reference standard solutions of nine different nuclides. The sources, which had a volume of 1 ml, were placed in the well of the detector. As gamma cascade-emitting nuclides were also used, in order to cover the whole energy range up to 2 MeV, corrections for summing effects were carried out. (auth)

57741 RECTIFYING PROCESS IN SURFACE BARRIER DETECTORS. Torreiter, A.; Siffert, P. (Laboratoire de Physique des Rayonnements et d'Electronique Nucleaire, Strasbourg). pp 107-18 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Present understanding of the physical processes underlying the rectifying mechanism of the metal–semiconductor surface-barrier diode is summarized. For a given metal the surface potential is largely independent of temperature and of the doping level of the base material, but it depends on the ambient atmosphere. An equilibrium is reached in a time determined by the kinetics of the chemical reaction, rather than by the carrier transit time through the oxide layer. The surface potential is then given by the electrochemical potential of the chemical species present. Such a physicochemical model is completely opposite to Schottky's theory. (R.W.R.)

57742 SPECTRAL NOISE INTENSITY OF SILICON DETECTORS. Feigt, I.; Jaentsch, O. (Siemens AG, Erlangen, Ger.). pp 180-7 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Measurement of the spectral noise intensity of silicon detectors is discussed. The noise of such detectors originates primarily at the surface. It has $1/f$ (mainly) and $1/f^2$ character up to frequencies of nearly 10^6 Hz, and can be strongly influenced by changing surface conditions. Measurements on diffused and Li-drifted Si detectors are presented. The diodes have good proportionality between the noise current and the reverse current; however, some have an exponential increase of the noise. (R.W.R.)

57743 EXPERIENCE WITH SEMICONDUCTOR DETECTORS AS DOSIMETERS IN A CLINICAL ENVIRONMENT. Parker, R. P. (Inst. of Cancer Research, Sutton, Eng.). pp 221-34 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The use of silicon diodes for clinical dosimetry is discussed. Those factors that go into the choice of detector parameters and the associated electronic equipment are considered. The advantages and disadvantages of these detectors and their routine use are reported. (R.W.R.)

57744 MINIATURIZED NEEDLE-TYPE SEMICONDUCTOR DETECTORS FOR IN-VIVO MEASUREMENTS OF TRACER ACTIVITY. Lauber, A. pp 235-52 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

A set of miniature detector probes for measurement of beta and gamma tracer activity in vivo is described. The probes use a lithium-compensated p–i–n silicon detector as sensing element. The standard "needle probe" contains a cylindrical detector 0.9 mm in diameter and 3 mm long, enclosed in a stainless steel tube 1.1 mm in outer diameter and with walls 50 μm thick. For particular applications several modified types were developed: probes with larger sensing elements, probes with extra-thin walls for low-energy beta detection, probes with two or three sensing elements in the same needle, and probes containing a movable sensing element. (auth)

57745 TECHNICAL AND PHYSICAL DETAILS ON MANUFACTURING AND IN VIVO APPLICATION OF MINIATURIZED SEMICONDUCTOR DETECTORS. Linhart, G. (Univ., Giessen, Ger.);

Allwein, M.; Pfeiff, H. pp 253-62 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Miniaturized semiconductor counters of n-silicon used for measurements in vivo are examined. Improvements in the areas of mechanical stability, better surface protection, and geometrical design are presented. Characteristic behavior under expected conditions is demonstrated. (auth)

57746 DESIGN CRITERIA OF RADIATION RESISTANT SEMICONDUCTOR NEUTRON DETECTORS. Graul, J. (Technische Hochschule, Munich). pp 270-83 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

For the direct measurement of high neutron flux densities (>10^9 n/cm^{2}sec) by radiation-induced dc current, polycrystalline semiconductor material can be used. If the electrical parameters are chosen in such a way that the sensitivity of the detector is at the minimum needed for the measurement, an improvement in radiation resistance of approximately a factor of 100 may be gained in comparison to single-crystal surface-barrier detectors. (R.W.R.)

57747 SEMICONDUCTOR GM COUNTER. Keil, G.; Ruge, I. (Institut fuer Technische Elektronik, Munich). pp 284-301 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

At a detector bias greater than the breakdown voltage, the discharge in a p—n junction is limited only by the positive internal resistance of the diode. If the breakdown area is small, the breakdown current flows in the form of current pulses of constant amplitude that are triggered by single minority carriers and that are quenched by a statistical process. In this mode the diode behaves like a Geiger—Mueller counter. The development of such a detector and its characteristics are described, and circuits for stabilization of the operating point and possible applications are given. (R.W.R.)

57748 GAMMA ENERGY RESOLUTION OF MULTIPLYING DETECTORS. Berg, G.; Heuberger, A. (Institut fuer Technische Elektronik, Munich). pp 319-30 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Just as the ionization chamber and G—M counter have semiconductor analogs in the Ge(Li) detector and breakdown counter, the multiplying detector is analogous to the gas proportional counter. The principle on which the multiplying γ-detector works is briefly described, and then the various contributions to the noise of the detector are considered in some detail. (R.W.R.)

57749 CHARGED PARTICLE DETECTORS MADE BY IMPLANTATION. Garin, A. (CEN, Saclay, France); Oria, M.; Waast, B. Radiat. Eff.; 10: No. 1-2, 43-8(Jul 1971).

The process of ion implantation was applied to the fabrication of both windowless charged-particle detectors and position-sensitive detectors; the ions used were lithium, boron, and phosphorus. The beams of boron and phosphorus ions were produced by a classical isotope separator, the lithium ion beam by an apparatus built in the laboratory. The optimum operating conditions were chosen by measurements of the implantation profiles of several diodes produced under different conditions. The results of tests for PN and PIN charged-particle detectors are presented. (auth)

57750 PERFORMANCE OF FOIL SUPPORTED ELECTRODE SYSTEM AND PLANS FOR IMPROVEMENT. Neumann, M. J. (Univ. of Chicago). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 84-5(Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The use of foil-supported wires for counter arrays is considered. Previous problems are ameliorated by using a good insulator for supporting the foil and eliminating the field distortion caused by surface charges through a self-shielding geometry. (R.W.R.)

57751 LOW-NOISE, WIDE-BAND, CURRENT-PULSE PREAMPLIFIERS FOR NEUTRON COUNTERS. De Lorenzo, J. T. (Oak Ridge National Lab., Tenn.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 114-16(Apr 1971).

An improved, low-noise, wide-band current preamplifier was developed for use with a fission counter having a 100-nsec electron collection time. The signal-to-noise ratio of the preamplifier and its insensitivity to component parameter variations and temperature changes exceed that of any commercially available unit. A differential version was developed to exploit the balanced configuration of the counter. A 20% improvement in signal-to-noise ratio was obtained with good common-mode rejection from 50 kHz to 30 MHz. (auth)

57752 STUDY ON DETECTION METHODS OF ^{14}C-LABELLED COMPOUNDS. Isoi, Koichiro; Ishida, Kazuko; Ikeda, Yoko (Mukogawa Women's Univ., Nishinomiya, Japan). Mukogawa Joshi Daigaku Kiyo, Shizenkagakuhen; No. 17, 357-9(Aug 1970). (In Japanese).

When biosynthesis path of C_6-C_3 type compounds was investigated with [^{14}C−(U)]-phenylalanine as a tracer, chromatoscanners, autoradiography and liquid scintillation counters were used to detect radioactive substances. These three methods for the detection of ^{14}C-labelled compounds were compared with one another. The detection limit of the autoradiography was lowest. Chromatoscanner and liquid scintillation counter methods had the lower detection limits of the same order. As an application, a purity test of commercial [^{14}C−(U)]-phenylalanine was performed. It was found that for quantitative tests, the liquid scintillation counter method was most effective, and for qualitative tests, autoradiography was most suitable. (Japan)

57753 ESTIMATION OF COEFFICIENT OF LUMINESCENCE IN ORGANIC SCINTILLATOR BY USING DIGITAL COMPUTER. Nishikawa, Kiyoshi (Konan Univ., Kobe, Japan); Ishiketa, Tadashi. Mem. Konan Univ., Sci. Ser.; No. 13, 1-21(Nov 1970).

In determining energy spectra of gamma rays using organic scintillators with electronic digital computers, relations between the range or energy loss of recoil electrons in the scintillators through Compton scattering processes and the pulse height in the output of photomultiplier tubes must be numerically obtained. If gamma rays of energy E make stochastically the recoil electrons having kinetic energy T through Compton scattering, and the electrons have the range R in the organic scintillators or have the energy loss ϵ along the range R, probability functions of K_1 (R,E) or K_1 (ϵ,E) of the above process were estimated by Monte Carlo simulation, while the pulse height (V) distribution was represented as a function g(V). These results are shown. The obtained relationship is expressed as coefficients $a = \Delta V/\Delta R$ or $\alpha = \Delta V/\Delta\epsilon$. These are coefficients for the efficiency of luminescence. (Japan)

57754 MULTICRYSTAL TOMOGRAPHIC SCANNER FOR MAPPING THIN CROSS SECTION OF RADIOACTIVITY IN AN ORGAN OF THE HUMAN BODY. Brill, Aaron B.; Patton, James A.; Erickson, Jon J.; King, Paul H. (to United States Atomic Energy Commission). U. S. Patent 3,591,806. 6 Jul 1971. Filed 17 Mar 1970.

A multicrystal tomographic scanner is utilized for mapping thin slices or cross sections of radioactivity in an organ of the human body which has been injected or ingested with a suitable radioisotope. A plurality of radiation detectors are arranged in a cylindrical monoplanar array with each detector focused in such a manner that the fields of view of all of the detectors intersect at a common point, and the detectors are driven mechanically such that this common point of the detectors is caused to move in a rectilinear raster of about 8 inches square. The distribution of radioactivity measured by the detectors due to the amount of radioisotope within the area being scanned is stored in a computer memory and reproduced on an oscilloscope display, as the section is being examined. (auth)

57755 RADIATION DETECTOR: SOLID STATE RADIATION DETECTION USING AN INSULATOR BETWEEN THE EMITTER AND COLLECTOR. Warren, Holland D. (to Babcock and Wilcox Co.). U. S. Patent 3,603,793. 7 Sep 1971. Filed 1 Aug 1969.

An improved self-powered detector which affords a prompt response to changes in the neutron and gamma flux incident upon a ytterbium emitter by using a thickness of insulator between the emitter and collector that is sufficient to absorb delayed electrons emitted at a lower energy level from the emitter and yet allow prompt electrons emitted at a higher energy level from the emitter to reach the collector is described. By thus eliminating the delayed electrons, the signal output current of the detector represents the instantaneous value of the incident neutron and/or gamma flux. (auth)

57756 RADIATION DETECTOR WITH GAS-PERMEABLE RADIATION WINDOW. Kimmel, Hermann. U. S. Patent 3,603,831. 7 Sep 1971. Priority date 13 Sep 1967, Germany.

A detector for ionizing radiation of relatively low energy of the

XUM

type in which a normally nonionized gas in a chamber connects two high-voltage electrodes and is ionized by radiation entering the chamber through a window in the chamber wall relatively permeable to the radiation, provided with a window of fine wire gauze and continuously supplied with gas under a pressure sufficient to prevent entry of contaminants from the environment through the openings in the gauze, is described. The screen window is more permeable to low-energy radiation than known windows. (auth)

57757 SEGMENTED GAMMA RAY DETECTOR AMPLIFIER SPECTROMETER. **Chase, Robert L.** (to United States Atomic Energy Commission). U. S. Patent 3,603,796. 7 Sep 1971. Filed 23 Jan 1969.

An amplifier for use with a segmented-gamma ray detector employing internal detector summing of the linear signal to eliminate the need for complicated external preamplifier gain adjustment and stability is described. Each segment of the detector is capacitively coupled to a voltage sensitive preamplifier and a charge preamplifier takes the whole charge of the detector. (auth)

57758 METHOD AND APPARATUS FOR MEASURING FAST NEUTRON FLUENCES WITH CADMIUM SULFIDE OR CADMIUM SELENIDE. **Johnson, Ralph T. Jr.** (to United States Atomic Energy Commission). U. S. Patent 3,588,505. 28 Jun 1971. Filed 30 Jun 1969.

An apparatus and method for measuring neutron fluences including a body of material having elements therein which are transmuted by neutrons into radioisotopes which decay by emission of radiation and produce ionization in the body of an amount relatable to the intensity of the neutron fluence are described. The neutron fluence is calculated by measuring the original electric conductivity of the body, exposing it to the neutron fluence, measuring the change in conductivity of the body due to the ionization from the decay of the radioisotopes transmuted by the neutrons, and computing the fluence, taking into account the time of decay of the radioisotopes; or, alterntatively, after exposure to the neutron fluence detecting each ionization event, determining the event rate, and computing the fluence, taking into account the time of decay of the radioisotopes. (auth)

57759 PHOTON DETECTOR UTILIZING A WELL-TYPE SCINTILLATION CRYSTAL. **Mays, Charles W.; Lloyd, Ray D.; Atherton, David R.** (to United States Atomic Energy Commission). U. S. Patent 3,591,807. 6 Jul 1971. Filed 6 Sep 1966.

A novel photon detector is described. The preferred embodiment comprises a scintillating crystal having a uniquely oriented counting chamber disposed transversely within the scintillating crystal, and the crystal has a plurality of planar faces uniformly spaced from the counting chamber to accommodate a plurality of photomultiplier tubes. The novel photon detector has the capability of achieving a uniform counting rate independent of sample position or sample volume and shape. (auth)

57760 RADIATION DETECTOR FOR INSERTION INTO A BLOOD VESSEL. **Kobayashi, Tetsuji; Seiichi, Takayanagi** (to Tokyo Shibaura Electric Co., Ltd.). U. S. Patent 3,598,109. 10 Aug 1971. Filed 11 Sep 1967.

A radiation detector for medical use to be inserted into the blood vessel is provided with a blood channel disposed in parallel with the blood flow. A semiconductor element is placed in the blood channel to detect the radiations from the radioisotope introduced into the blood vessel, with the radiation-receiving face thereof exposed to the interior of the blood channel. (auth)

57761 POWER METER FOR MEASUREMENT OF RADIATION. **Mefferd, Wayne S.; Rorden, Robert J.; Hobart, James L.** (to Coherent Radiation Labs., Inc.). U. S. Patent 3,596,514. 3 Aug 1971. Filed 2 Jan 1968.

A power meter for measuring radiation including a radiation target disc, a heat sink for cooling the periphery of the disc, and a circumferentially extending array of radial thermocouples for measuring the total power of energy incident of the central area of the disc as a function of the sum of radial temperature gradients of the disc is described. (auth)

57762 CHARACTERISTICS OF HIGH PURITY GERMANIUM AND SILICON RADIATION DETECTORS. **Drummond, William Eric.** Stanford, Calif.; Stanford Univ. (1971). 63p. University Microfilms Order No. 71-19,675.

Thesis.

Characteristics of silicon and germanium radiation detectors are developed from an analysis of the energy-loss mechanisms for hot carriers. A calculation of the probability of ionization versus primary electron energy in silicon indicates an effective ionization threshold several times the bandgap energy. Calculations give an average energy expended per created pair (ϵ) of 4.24 eV. Closer agreement with the experimental value of 3.67 eV is achieved by lowering the phonon to ionization scattering rate ratio. Temperature effects, which enter through changes in the bandgap, are calculated to be $\partial\epsilon/\partial E_g = 1.73$. The analysis also predicts a Fano factor for silicon of 0.059. Discussion of the germanium situation is based on the premise of hot-carrier behavior similar to that in silicon. Because germanium has a more complicated bandstructure, two sets of calculations are made using different effective bandgaps. With $\epsilon = 2.96$ eV at 90°K, very similar results are obtained in both cases and indicate $\partial\epsilon/\partial E_g \approx 1.77$ and $F \approx 0.066$. The fabrication and characterization of high-purity germanium radiation detectors is also described. These detectors are n–i–p diodes with a shallow (1.5-μ) diffused junction and a noninjecting metal–semiconductor contact. Electrical measurements show that with 500 volts of bias these detectors are fully depleted and have a capacitance of approximately 4.5 pF. Detection characteristics are determined from measurements of γ rays and x rays over the energy range of 6 keV to 136 keV. A deviation from linearity of less than ±0.2 percent was measured. The resolution of the detectors is characterized by an effective Fano factor of 0.12. The average energy expended per created pair was determined to be 2.95 ± 0.02 eV at 90°K. (TSS)

57763 DOUBLE-DETECTOR SCINTICAMERA FOR VISUALIZATION OF COLD NODULES IN BULKY ORGANS. A PRELIMINARY PHANTOM INVESTIGATION. **Mikolajkow, A.; Jasinski, W. K.** (Inst. of Oncology, Warsaw). Nucl.-Med.; 10: No. 2, 201-3(15 Jul 1971).

An investigation of a liver-slice phantom embedded in a thick Perspex block was carried out to determine the performance of a double-detector scinticamera. Results indicate that when a scintigraphic examination is aimed at the detection of cold nodules situated in unknown positions in bulky radioactive organs, the performance of a two-detector camera may be better than that of a conventional instrument. (W.H.K.)

57764 LIEGE ANTHROPOGAMMAMETER AND ITS CLINICAL USE. **Heusghem, C.; Delwaide, P. A.** (Univ., Liege). Bull. Acad. Roy. Med. Belg.; 9: 439-95(1969). (In French).

The Liège whole-body counter consists of a plastifluor detector of approximately 4 π geometry, 18 photomultipliers and a 3-channel spectrometer. Its principal characteristics are described including resolution, which is relatively low, and efficiency, which exceeds 50%. Efficiency is constant throughout a wide range of activities. For measurements of body ^{40}K and ^{137}Cs, interference due to the low discrimination requires the use of an indirect method of calibration based on algebraic manipulation of the values obtained. Under these conditions, a counting time of 200 seconds yields body potassium values that are precise and reproducible to within 5%. Initial values obtained by measurements in normal subjects are in agreement with findings reported in the literature; pathological variations can thus be compared with reliable indices according to age and weight. Patients with cirrhosis of the liver, diabetes and essential hypertension show lower potassium body content than the predicted normal values, when analyzed statistically. The body counter also is useful for radioactive contamination controls; particularly the ^{137}Cs body burden is in all cases measured. Examples of metabolic studies with one or two tracers in the fields of pharmacology and toxicology are also reported. (auth)

57765 NONLINEAR RESPONSES OF POLY(VINYL TOLUENE) PLASTIC SCINTILLATORS AT HIGH EXCITATION DOSES. **Powell, R. C.; Harrah, L. A.** (Sandia Labs., Albuquerque, N. Mex.). J. Chem. Phys.; 55: No. 4, 1878-84(15 Aug 1971).

The light output intensities from commercial Pilot B and similar plastic scintillators having a poly (vinyl toluene) host were measured as a function of dose from a pulsed electron beam machine. At doses exceeding $\sim 1.5 \times 10^4$ rad in 3×10^{-9} sec, nonlinear responses were observed. For pure poly (vinyl toluene) the nonlinear responses can be explained by bimolecular interaction of the host excited states, and the product of the excited-state yield times the interaction rate constant is 8.5×10^{-10} cm^3 sec^{-1} per 100 eV. For Pilot B it is concluded that the dominant quenching mechanism is the reabsorption of scintillator light by mononegative ions of the center fluor, p-terphenyl. This conclusion is corroborated by the observation of the spectrum of decreased light transmission through the sample after electron excitation at high doses. The observed product of ion yield times extinction coefficient is 2.3×10^5 liter mole^{-1} · cm^{-1} per 100 eV. (auth)

57766 X-RAY SENSITIVITY OF SEMICONDUCTOR RADIATION DETECTORS. **Gorenburg, L. S.; Pogrebnoi, Yu. P.** Defektoskopiya; No. 2, 98-107(1971). (In Russian).

The application of semiconductor radiation detectors to ionization defectoscopes is described. The x-ray sensitivity of various types of semiconductor detectors was investigated, and the dependence of the sensitivity on their class was established. The relaxation characteristics of semiconductor detector operation with alternating current at 50 Hz was studied as affected by x-radiation. Recommendations are offered concerning the feasibility of using semiconductor detector types of defectoscopes and automated devices in radiation fields. (tr-auth)

57767 RECENT ADVANCES IN RADIATION PROTECTION MEASUREMENT TECHNIQUES. Brunner, H. (Eidgenoessisches Institut fuer Reaktorforschung, Wuerenlingen,Switzerland). pp 181-204 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A review is given of recent developments of techniques and detectors in the fields of external counting of incorporated radionuclides, detectors suitable for neutron dosimetry under normal and accident conditions, assessment of inhalation exposures and other applications for individual dosimetry. The performances of available methods and detectors are compared to the requirements and experiences of applied health physics. (155 references) (auth)

57768 ABSOLUTE MEASUREMENT OF FLUENCE AND FLUX DENSITY OF LOW-ENERGY X- AND γ-FIELDS BY SEMICONDUCTOR DETECTORS. Gossrau, M.; Drexler, G. (Inst. fuer Strahlenschutz, Neuherberg, Ger.). pp 205-10 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The description of a radiation field by the spatial distribution of the energy flux density or the fluence has been used in standard dosimetry for a long time as these physical quantities could be determined from calorimetric measurements. For low-energy X-rays total absorbing ionization chambers and silicon surface-barrier counters have been employed to measure energy fluence by the charge released in the detector. The use of a germanium pin diode detector is investigated. The main advantages are the simple experimental arrangement and the fact that, even at very low dose rates, the detector current can easily be measured with great accuracy. The effects of recombination and trapping of charge carriers as sources of systematic errors are discussed. The effect of incomplete absorption of γ-radiation has been taken into account by a Monte Carlo calculation. The lower limit of the measurement range can be estimated to be 20 $\text{erg} \cdot \text{cm}^{-2} \cdot \text{sec}^{-1}$. To compare the method with other techniques mentioned, a set of five X-ray qualities were used to obtain the photon spectra. It can be shown that the energy of 2.98 ± 0.01 eV needed to produce an electron-hole pair in germanium provides the possibility of determining the fluence of an X- or γ-field in the energy range under consideration to an accuracy of ±3.0%. (auth)

57769 PLANAR DISTRIBUTION OF LOW-ENERGY β-NUCLIDES USING COMPUTER CONTROLLED EQUIPMENT WITH A SEMICONDUCTOR DETECTOR, AND COMPARISONS WITH OTHER METHODS. Tykva, R. (Inst. of Organic Chemistry and Biochemistry, Prague). pp 211-24 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A procedure and apparatus used to determine the relative planar distribution of low-energy beta nuclides (e.g. ^{3}H, ^{14}C) or of certain other radionuclides (e.g. ^{32}P, ^{57}Co) is described. The method permits the determination of both individual radionuclides and larger numbers of radionuclides present in a sample. A specific radionuclide can be determined at various parts of the sample using the preset program with various accuracies and with various planar resolving powers. The maximum sample height is 5 mm, and the planar dimensions may be approximately 82 mm × 88 mm. The computer-controlled detection system uses a partially-depleted surface barrier silicon detector placed in the evacuated space above a table that constitutes the sample support and that can be moved in the plane of the table. The minimum scanned area is 1 mm × 1 mm. The fully-automated evaluation of individual scanned sites is effected numerically in terms of measured counts per time interval, chosen arbitrarily and displayed graphically with different levels indicated by distinguishing colors. The contours of the sample can also be displayed. One single detector determines the contours of the sample, for thicknesses between 0.02 mm and 2.9 mm. The method can be also used for the radioactivity determination of individual discrete samples (e.g. in dry residues of samples) or for detection on paper strips. The application of the method for histologic sections of mouse embryos and for gel electrophoresis is described. The results obtained by the method described are compared with the results obtained either by autoradiography of identical planar preparations or using a liquid scintillation spectrometer after isolation of samples from the individual scanned sites of the planar preparations. The basic parameters of semiconductor detection are also compared with the results of measurements using a Geiger-Müller counter with a thin window, a 2 π windowless flow counter, and an internal proportional gas counter. (auth)

57770 IN VIVO MEASUREMENT OF PLUTONIUM AND OTHER VERY LOW ENERGY EMITTERS. Huth, G. C.; Moldofsky, P. J. (General Electric Co., Philadelphia). pp 225-34 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A new type of radiation detector, the silicon avalanche diode, has made possible the previously impossible in vivo measurement of beta radiation as low as 5 keV and X-ray and gamma radiation as low as 1 keV. The solid state analogue of the proportional counter, the avalanche diode, provides internal charge gain within the silicon wafer, raising the radiation-induced signal far above the detector noise level. By this mechanism, radiation formerly below detector noise level can be detected with extremely low background (on the order of 1 count per minute) at temperatures up to 100°C. Applications are being explored in nuclear medicine in the fields of bone scanning with ^{125}I, eye tumor studies with ^{32}P and ^{125}I, rapid analysis of skin cancer response to treatment (^{32}P) and in vivo detection of plutonium via the 13.6, 17.4, 20.5 keV L X-rays from the uranium daughter. All these applications make use of the three principal characteristics of the avalanche detector: internal gain; small size—as small as 3 mm (or as large as 30 mm) diameter; and low noise and high sensitivity even at elevated temperatures. Currently, in vivo measurements of plutonium lodged in bronchial and metastinal lymph nodes behind the lungs are proceeding using a flexible detector probe that is inserted in the oesophagus, in effect, partially swallowed. The experiments are performed with dogs whose inhaled plutonium has been filtered by these nodes from the lungs. At present, a minimum detectable amount at an 84% confidence level of ^{239}Pu of typical composition (i.e., including small amounts of other isotopes) detected by an avalanche detector in the oesophagus is about 20 nCi. The results of the nuclear medical investigations being carried out by a dozen physicians throughout the United States on these and other applications indicate that the avalanche detector is making possible, in many cases for the first time, reliable in vivo measurement of extremely soft radiation with drastically reduced background and over a wide temperature range. (auth)

57771 SOFT X-RAY SPECTROMETRY WITH SEMICONDUCTORS OPERATING IN A CASCADE REGIME. Peyre-Lavigne, A. (Universite Paul Sabatier, Toulouse); Peyre-Lavigne, Monique; Blanc, D.; (and others). pp 241-52 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The detection of soft X-rays is an important problem in radiological protection, especially in the matter of external counting. With a view to such applications, silicon detectors were constructed operating in the cascade régimes. Having calculated the internal multiplication factor and the background noise of such a detector, the types of structure that could be used for designing spectrometers of good quality were determined. These are, in order of merit, diodes (n type or p type metal semiconductors) and P + N and N + P diffusion junctions. The threshold voltage of the cascade is obtained by measuring the characteristics (inverse-current, voltage) and the corresponding capacitance. Measurements of noise level as a function of polarization voltage were combined with those of the multiplication factor and of current intensity due to microplasmas. The presence of microplasmas was found to be closely linked with the technology of detector design. The spectrometric characteristics of the detector, obtained by irradiation with alpha particles from a ^{241}Am source, are given. (auth)

57772 ASSAY EFFICIENCY AND RESPONSE FOR CYLINDRICAL SCINTILLATION CRYSTALS AND LARGE-AREA GAS COUNTERS APPLIED TO WHOLE-BODY COUNTING. Morsy, Samira M.; Abu-Bakr, M. Y.; Aloush, A. A.; Youssef, S. K. (Atomic Energy Establishment, Cairo). pp 253-67 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological

XUM

radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A new method for evaluating the efficiency of assay for some conventional whole-body counting arrangements is given. The evaluation is based on a generalized formula for calculating the total absolute detection efficiency in the case of a cylindrical scintillation crystal and a large-area gas counter for ^{239}Pu detection. For the cylindrical scintillation crystal, the effect of body thickness on the response and assay efficiency was taken into account by considering the human body to be represented by an elliptical cylinder of finite length equal to that of a standard man. The attenuation length inside the phantom was calculated by solving simultaneously the equation representing the direction of the emitted photon and that representing the surface of the phantom. For this case the relative values of the detection efficiency for a point source moving inside the phantom in chair geometry are given. In scan geometry, the effects of scan length on both the response and the efficiency are examined. In the case of the large-area gas counter, the effect of source position on the detection efficiency was examined. The absolute value of the detection efficiency has also been computed for different thicknesses of the counter. The main advantage of the present method is the realistic simulation of the counting arrangements, for which optimization studies can be performed, not only with respect to some given geometry, but also for the purpose of selecting the most appropriate geometry. The results reflect the accuracy inherent in the evaluated activity for the different geometrical arrangements. Such inherent accuracy has to be considered in the course of determining the corresponding radiation dose. (auth)

57773 DIRECT MEASUREMENT OF PULMONARY PLUTONIUM CONTAMINATION. Boulay, P. (CEA, Bruyeres-le-Chatel, France). pp 287-97 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

For the direct measurement of pulmonary plutonium contamination the following three conditions must all be met: the detector used must have a suitable window surface and efficiency; the background noise should be very low; and it must be possible to reduce the error due to morphology. The counter proposed has a useful diameter of 190 mm and a mean efficiency of 60% for ^{239}Pu X-rays. The background noise is reduced by lead shielding, 10 cm thick, covered with 1 mm of stainless steel, an anti-coincidence circuit and a pulse rise-time discriminator. Under these conditions the sensitivity threshold can be estimated at 5 nCi of ^{239}Pu for a standard man. A method of internal calibration of the individual based on additional ^{233}Pa overloading is proposed. (auth)

57774 MULTIPLE PROPORTIONAL GAS COUNTER FOR THE CARTOGRAPHY OF RADIOELEMENTS. Allemand, R.; Brey, C.; Gagelin, J. J.; Laval, M. (CEA, Grenoble, France). pp 327-34 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Work already done on the visualization of thermal neutron diagrams (neutron diffraction) has been applied to studies on the visualization of X-ray or gamma emitters using proportional (gas) counters. The use of induced electric charges permits each nuclear event detected in the gas to be associated with two electrical signals on two different electrodes. These electrodes are geometrically positioned and interconnected so as to form a matrix, each point of this matrix constituting a detection cell. For each event there is then a corresponding address (X, Y). Each line and each column comprises an electronic measurement path so that a coincidence logic (X, Y) permits addressing of the information in a storage and visualization element. The encouraging results obtained on an experimental chamber have enabled the development of a multicounter intended for use in the cartography of ^{125}I-labelled thyroid glands. The device developed also makes it possible to analyze simultaneously the diagrams of powders or monocrystals. This method, when adapted for external counting can determine precise location of body burdens of X, gamma, or beta emitters. (auth)

57775 MEASUREMENT OF FAST-NEUTRON SPECTRA WITH THRESHOLD DETECTORS. Kramer-Ageev, E. A.; Troshin, V. S.; Tikhonov, E. G.; Ushakov, S. N. (Inst. of Engineering Physics, Moscow). pp 365-71 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Threshold detectors are a useful tool for the study of fast-neutron spectra, which are necessary for solving many problems in radiation physics, including the determination of the tissue dose of neutrons in emergency situations. Several methods of calculating high fast-neutron fluxes have been developed including representation of the fast-neutron spectra in the form of a series expansion in terms of orthonormalized functions, the expansion coefficients being sought from the condition of minimum standard deviation; a series expansion of the spectrum in terms of a system of orthogonal functions consisting of threshold cross-sections; and an iteration method using the Bayes conditional probability theorem. However, all the above-mentioned methods are very sensitive to errors in the initial data. The proposed method is suitable for analyzing the spectra of comparatively low fast-neutron fluxes. It consists in calculating the integral neutron spectra from the measured activities and effective threshold cross-sections and representing the differential spectrum sought as an exponent in each interval selected (not less than 1 MeV in width). The latter interval includes the effective thresholds of at least two reactions. The spectrum values at the boundaries of the interval are determined successively from the higher to the lower energies with the help of the transcendental equations. The indeterminateness in the spectrum obtained by this method is 10%, when the initial data are correct to within approximately 5%. The method permits the use of iterative refinement for the spectra which differ considerably from the fission spectrum. (auth)

57776 NEUTRON DOSIMETRY WITH RADIATION ELEMENTS. Hosemann, R.; Haase, J.; Junker, D.; Melde, D. Fritz-Haber Institut, Berlin). pp 373-80 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The radiation element is a vacuum cell with two special electrodes that are charged when irradiated. The resulting potential difference is measured with a quartz-fibre electrometer. Radiation elements are self-powered, measure radiation doses independent of dose rate and have a practically unlimited storage time due to their extremely good insulation. Radiation elements become charged if the electrodes emit different numbers of electrons. This is achieved for X-rays and γ-rays by using electrodes made of materials of different atomic numbers. Slow neutrons are captured in an electrode made of silver or rhodium by a (n,γ) process producing short-lived β-active isotopes. For fast neutrons a moderator must be used. Fortunately the human body has the optimum dimensions required for this purpose. Dosimeters with radiation elements therefore cannot measure free air doses of neutrons, but careful investigations have proved that they are reliable indicators for neutron fields that are of interest in accident dosimetry. Dosimeters with silver electrodes of 0.9 cm o.d. yield a sensitivity of about 3.5 V/rad to thermal neutrons and 0.5 V/rad to epithermal neutrons, which correspond to full-scale readings of about 30 rad and 200 rad, respectively. Dosimeters with the same sensitivity to thermal and epithermal neutrons and γ-rays have full-scale readings of 500 rad. Doses between about 50 and 500 rad, which require immediate medical attention, can be read off directly, whereas the less dangerous doses, between 5 and 50 rad, are stored latently and can be read off later. (auth)

57777 PHYSICAL CHARACTERISTICS OF DIRECT-CHARGE DETECTORS. Ivanov, V. I.; Kulakov, G. V.; Makhaneva, G. I. (Inst. of Engineering Physics, Moscow). pp 381-90 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The results of studies on the physical characteristics of direct-charge detectors ("radiation elements") designed to measure gamma- and neutron radiations are presented. Data on the relationship between accumulated charge and the form, material and thickness of electrodes, and electrode spacing are discussed. The influence of space charge on the upper measurement limit is considered from a theoretical viewpoint. Detector sensitivities calculated on a computer are also given. Various aspects of the practical application of direct-charge detectors are discussed. (auth)

57778 IONIZATION CHAMBERS WITH A LIQUID DIELECTRIC. Ivanov, V. I.; Kleshchenko, E. D.; Frolov, V. V. (Inst. of Engineering Physics, Moscow). pp 391-7 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The mechanism of ionization current generation under the action of radiation is studied. Volt-ampere characteristics are analyzed and various aspects of the practical application of liquid ionization chambers to the measurement of ionizing radiations are discussed. (auth)

57779 MONITORING SYSTEM FOR THE ASSESSMENT OF REACTOR SHIELD PERFORMANCE. Lakey, J. R. A.; Martin, A. (Royal Naval Coll., Greenwich, Eng.). pp 445-52 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The objectives of a shield survey and the results of intercomparisons are presented, and recommendations on the selection of a monitoring system are given. The performance of a reactor shield must be assessed efficiently to enable immediate repairs to be made to defective shields. Correlation of survey results with shield designer's predictions has proved difficult and the factors contributing to the disagreement have been examined. The shield designer uses flux-to-dose conversion factors which neglect the radiation equilibrium situation at the shield-air interface and the effect of attenuation and scattering external to the shield. The presence of the operator can significantly influence a measurement. The use of the "maximum exposure dose" (MED) concept is recommended for gamma photon predictions and this is compared with absorbed dose measurements in phantoms. Shield survey instruments must have a flat response over a wide range of energies. For example, many gamma dosimeters are designed for use at energies up to about 2 MeV whereas around most reactors a proportion of dose is due to 6 MeV gamma photons, with some contribution from higher energies. Tests were carried out to select suitable detectors using actual reactor operating conditions and simulated conditions at specific energies, notably 6 MeV. In practice discrepancies exceeding a factor of 3 were frequently found. A comparison was made between thermoluminescent dosimeters and film badges for the purpose of fixed position integrating dosimeters. The film dosimeter (AERE/RPS) was found to over-estimate by a factor of 2 for 6 MeV gamma radiation and in practical situations over-estimated by 20 to 80%. Thermoluminescent dosimetry is recommended for shield surveys provided that a build-up cap is used to achieve charged particle equilibrium. (auth)

57780 DETECTION AND ALARM SYSTEM FOR ACCIDENTIAL NUCLEAR EXCURSIONS. Benezech, G.; Gey, A.; Guillot, P.; Prigent, R.; Renard, C. (Commissariat a l'Energie Atomique, Cadarache, France). pp 453-63 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Since 1964 the CEA has developed two criticality detectors and had them placed on the market: one is sensitive to gamma radiation and consists of a scintillator in combination with a photomultiplier; the other is sensitive to neutron radiation and consists of a junction diode located opposite a concentrated uranium target. The entry into operation in 1969 of the CRAC device, which employs full-scale simulation of accidents in the liquid phase, has shed light on the specific dynamics of accidents which require extensive modifications in the system as developed. A new generation of equipment has therefore been studied; this has benefited from the greatly increased knowledge of the characteristics of criticality accidents and the improvements made in electronic components during the last few years (miniaturization, performance, reliability, etc.). Experiments have been carried out on a combined detector which is sensitive to both neutron and gamma radiation; this is an alarm device which responds to a predetermined dose over a wide dynamic range (10^6), the sensitivity of which covers practically all types of accident which may occur in the liquid phase and give rise to a significant irradiation hazard to personnel. It consists of a scintillator, whose response curve is proportional to the neutron + gamma radiation dose, coupled to a photoelectric cell operating in conjunction with an electronic measurement device; the triggering dose is 25 mrad, its insensitivity to a continuous dose rate being 300 mrad/h. Apart from its effective dose response, the main advantages of this detector are its very small dimensions and its attractively low cost. The principle of detection is still based on a logical two-out-of-three recognition system. The original features of the information processing case are such that the device is not affected by the dynamics of the accidents, regardless of the variations in sensitivity between each detector and their position in relation to the source. The logical signal transmitted by the detector is only retained in the alarm circuit if the detector reading is still above its threshold. However, if the threshold is momentarily exceeded due to the passage of a random source or an industrial parasitic signal, the fact is reported but cannot give rise to false alarm signals. (auth)

57781 ENERGY RESPONSE OF SOME COMMERCIAL BETA/GAMMA AND NEUTRON SURVEY INSTRUMENTS. Thompson, I. M. G.; Lavender, A.; Shipton, R. G.; Goodwin, Jane (Berkeley Nuclear Labs., Eng.). pp 505-31 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The variation in instrument response with energy is given for 29 commercially available gamma survey instruments in the photon energy range from 29 keV to 6 MeV and for five neutron survey instruments over the energy range 0.05 eV to 19 MeV. Details are also given of the radiation sources and the standardization of the radiation fields used for the energy assessments. (auth)

57782 INTERCOMPARISON OF THE CHARACTERISTICS OF BETA/GAMMA AND NEUTRON SURVEY INSTRUMENTS. Larson, H. V. (Battelle-Northwest, Richland, Wash.); Kathren, R. L.; Thompson, I. M. G. pp 533-65 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A knowledge of the radiological and electrical characteristics of instruments used for the estimation of radiation hazards to personnel is vital both in the selection of instruments to be used and in assessing the integrity associated with measurements made with them. An intercomparison of radiation tests and evaluation tests of electrical and environmental characteristics carried out at Berkeley Nuclear Laboratories, United Kingdom and Pacific Northwest Laboratory, USA, on two neutron rem counters and two beta/gamma survey instruments is described. This comparison has served as a useful check on the techniques used by both the laboratories and clearly demonstrates the difficulties associated with beta and neutron dose measurements. A recommended evaluation program for portable radiation survey instruments is outlined. (auth)

57783 17th NUCLEAR SCIENCE SYMPOSIUM AND 2nd NUCLEAR POWER SYSTEMS SYMPOSIUM, NEW YORK CITY, NOVEMBER 4-6, 1970. IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 10504(Feb 1971). (CONF-701109).

Separate abstracts were prepared for 70 papers. (R.W.R.)

For abstracts of individual papers see: 57359, 57360, 57395, 57784–57792, 57812–57821, 57892–57899, 57907, 57908, 58063, 58064, 58079, 58956, 59664–59668, 59898, 59899, 60001–60003, 60041–60043, 60050–60053, 60089, 60090, 60133–60135, 60180–60187, 60208, 60236, 60239, and 60248.

57784 SELF-TRIGGERED WIRE CHAMBERS FOR RADIATION IMAGING PURPOSES. Kaufman, Leon (Univ. of California, San Francisco); Perez-Mendez, Victor; Sperinde, Johnie M. IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 64-7(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Spark chambers with digitized readouts offer distinct advantages in spatial resolution and coverage over other gamma-ray imaging devices. These chambers usually require external logic signals for triggering; in this paper a method that provides self-triggering spark chambers is described. Initial tests of a 45-cm × 45-cm spark chamber with ^{60}Co and ^{198}Au samples are also described. (auth)

57785 WHOLE-BODY COUNTER FOR NEUTRON ACTIVATION ANALYSIS. Cohn, S. H.; Dombrowski, C. S. (Brookhaven National Lab., Upton, N. Y.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 73-8(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

For the measurement of total-body calcium, sodium, chlorine, nitrogen, and phosphorus by neutron activation analysis in vivo, there are two basic requirements. It is necessary to achieve a uniform neutron flux through the human subject. It is also necessary to measure the induced radionuclides in the body quantitatively. The Brookhaven 54-detector whole-body counter with its on-line computer satisfies this latter requirement by providing an absolute measure of the induced activity in the subject, independent of its location in the body and the size of the body itself. The application of this whole-body counter in the measurement of total-body calcium, sodium, chlorine, nitrogen, and phosphorus in vivo is described. (auth)

57786 FAST ELECTRONIC MODULES FOR NUCLEAR PHYSICS EXPERIMENTS. Horvath, Pavel; Ondris, Lubomir (Joint Inst. for Nuclear Research, Dubna, USSR). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 102-7 (Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Fast electronics modules for nuclear physics experiments are under design at Dubna. In this paper the following modules are described: a pulse shaper with a fixed discrimination level, a pulse shaper using the constant-fraction-of-pulse height technique, and a two-fold coincidence unit. The modules for discrimination and timing signals contain the fan-out standard circuit with both nanosecond logic and subnanosecond outputs. The compensation of temperature variations of the discrimination level and the compensation of time drift of subnanosecond output pulses is designed and introduced. In the pulse shapers after the temperature compensation was introduced, the long time stability and time drift of subnanosecond logic output pulses were measured and found to be within ±10 ps/24 hours. Attempts are made to build a coincidence–anticoincidence logic for nuclear physics experiments with the time resolution of 0.5 ns at FWHM. (auth)

57787 HIGH PURITY GERMANIUM FOR DETECTOR FABRICATION. Hall, R. N.; Soltys, T. J. (General Electric Research and Development Center, Schenectady, N. Y.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 160-5(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The preparation of large (100)-oriented germanium crystals with net concentrations of electrically active impurities in the range 1 to 10×10^{10} cm^{-3} is described. This material has been used successfully for the fabrication of semiconductor detectors having depletion layers up to 8 mm thick, without using lithium compensation. Electrical evaluation is performed by studying the Hall coefficient as a function of temperature, and by measuring the resistivity along the length at 77°K. Dislocation densities in most crystals range from 2000 to 5000 cm^{-2}. Several dislocation-free crystals were also grown. The oxygen concentration, measured by lithium precipitation, is approximately 10^{14} cm^{-3} in germanium grown from quartz crucibles and much less than this when grown from graphite. The solubility of lithium in pure, oxygen-free germanium is found to be 3.5×10^{13} cm^{-3} at 23°C. (auth)

57788 AVERAGE ENERGY EXPENDED PER IONIZED ELECTRON-HOLE PAIR FOR α PARTICLES IN Si(Li). Key, J. R.; Rabson, T. A. (Rice Univ., Houston, Tex.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 184-6 (Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

New results are obtained for the temperature dependence of ϵ, the average energy required to create an electron–hole pair by ionizing radiation, for α particles incident on lithium-drifted silicon surface-barrier detectors. For temperatures between 31 and 291°K, the application of fields up to 10^4 V/cm resulted in a saturated pulse height; this saturation eliminated the necessity for extrapolation procedures to determine ϵ. Between 4.2 and 31°K pulse height saturation was not observed. Below 31°K the presence of both fast- and slow-risetime components in the detector pulse prevented an accurate determination of the pulse height. A significant difference between the present results and those previously reported is that ϵ plotted vs the energy gap gives a linear curve over the entire range reported (31 to 291°K). (auth)

57789 METHOD OF CALIBRATION OF MOXON–RAE DETECTORS. Ellis, A. N.; Brown, W. K.; Farrell, J. A.; Fullwood, R. R. (Los Alamos Scientific Lab., N. Mex.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 205-7(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A method of calibration of the Moxon–Rae-type gamma-ray detectors used in neutron-capture cross-section measurements with underground nuclear explosions is described. The method consists of measuring the activation and detector signal in individual resonances in samples of ^{197}Au and ^{238}U exposed to a neutron beam from an underground nuclear explosion. The resonances are resolved by time of flight. Since both the activation and the corresponding detector signal are known, the efficiency can be determined without measuring the incident neutron flux or sample capture cross section. (auth)

57790 INSTRUMENT FOR THE MEASUREMENT OF AURORAL ELECTRONS AND PROTONS. Lawrence, Dennis O.; Harrington, Timothy M.; Lawrence, James L. Jr.; Josias, Conrad S. (Analog Tech. Corp., Pasadena, Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 237-48(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

An instrument to measure the energy spectrum of auroral electrons and protons was developed and is operational in orbit aboard ATS-5. It uses cylindrical coordinate electrostatic analyzers for detection of electrons and protons in the range of 50 eV to 50 keV. The analyzers focus these particles onto channel electron multipliers, which are followed by special-purpose amplifier–discriminator electronics. These electronics protect against counting losses due to gain degradation attributable to fatigue and to recovery effects associated with high counting rates. The pulse amplifiers have a dynamic range of 1000 : 1 and resolve 1-μs pulse pairs. Their fixed dead time (t_d) permits accurate correction to be made for counting rates exceeding $1/t_d$. A fast, ultrastable, programmable high-voltage scan system provides differential voltages between 0 and 6400 V in 62 exponential steps to the analyzer plates for energy selection. A digital servo permits either continuous sequential scanning over the 1000 : 1 range in energy, or automatic tracking of a spectral peak. Digital compression techniques are used to provide maximum data transfer to the spacecraft telemetry. (auth)

57791 PERFORMANCE OF LARGE GERMANIUM DETECTORS AT ELEVATED TEMPERATURES FOR SATELLITE APPLICATIONS. Nakano, G. H.; Imhof, W. L. (Lockheed Palo Alto Research Lab., Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 258-63(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A measurement program was undertaken to investigate design criteria for satellite-borne Ge(Li) detector systems. The resolution, pulse height, reverse current, and efficiency were measured as a function of temperature and bias voltage for large Ge(Li) detectors. For space applications the important parameters are the knees (rapid changes) in the resolution and leakage current versus temperature. These features are observed to vary appreciably from detector to detector. (auth)

57792 LABORATORY QUALITY CHARGE SENSITIVE AMPLIFIER SUITABLE FOR SPACE APPLICATIONS. Alexander, R. M. (TRW Systems, Redondo Beach, Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 264-74 (Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The amplifier described is designed for use with uncooled silicon nuclear-particle detectors commonly used in space instruments. The charge-sensitive preamplifier and two-stage shaping amplifier provides the performance of a laboratory quality instrument while simultaneously satisfying the stringent requirements imposed upon flight hardware. Double-differentiation–double-integration (DDDI) pulse shaping with pole-zero cancellation of the preamplifier decay time constant was selected on the basis of simplicity, adequate noise performance, and stability at high count rates. The components used in the design are compatible with hybrid microcircuit fabrication. Noise performance at 1 μsec DDDI time constants was measured to be 1.8 keV + 47 eV/pf FWHM (Silicon) for an amplifier consuming 100 mW. The operating temperature range is approximately −40° to +80°C. Further results of an extensive testing program are reported. (auth)

57793 RECENT TOPICS ON SEMICONDUCTOR RADIATION DETECTORS. Sakai, E. (Japan Atomic Energy Research Inst., Tokai). Genshiryoku Kogyo; 17: No. 6, 44-8(Jun 1971). (In Japanese).

A few topics on semiconductor radiation detectors are discussed. Low noise pre-amplifiers are being actively developed in order to realize very high ultimate energy resolution of Si and Ge detectors, and efforts are being made to manufacture large volume Ge(Li) detectors to obtain high gamma detection efficiency. Ge(Li) detectors manufactured by Li drift method are inconvenient because it must be continuously kept at liquid nitrogen temperature. If extremely pure germanium single crystals are obtained, p-n junction detectors might be manufactured by making n$^+$ and p$^+$ layers. Especially if the n$^+$ layer is made by implanting an n type impurity other than Li by the ion implantation method, the detectors may be usable, holding them at the liquid nitrogen temperature only during measurement. Also, GaAs and CdTe detectors are being investigated. They have possibilities of being operated as high resolution detectors at room temperature. The CdTe detectors also have the potential for neutron detection. (Japan)

Nuclear Spectroscopic Instrumentation

57794 (INS-TCH-5) ABSOLUTE MEASUREMENT OF ALPHA RAY BY A SURFACE-BARRIER TYPE SILICON DETECTOR. Komura, Kazuhisa (Tokyo Univ. (Japan). Inst. for Nuclear Study). 14 Mar 1971. 16p. (In Japanese). Dep. NTIS (U. S. Sales Only).

Performance tests of a surface-barrier type silicon detector purchased from ORTEC for α ray spectroscopy are described. ^{210}Po, ^{228}Th including daughter nuclides, natural uranium and ^{233}U fixed or electrodeposited on a stainless steel plate were used as α sources for measurement. ^{228}Th reached radioactive equilibrium in one month, and is useful as the source for measurement of energy resolution. Half-value width for α rays of 5.68 MeV from ^{224}Ra and 6.29 MeV from ^{220}Rn was approximately 65 keV as a result. The effective radii of the detectors were experimentally determined to be 18.0 ± 0.1 mm, and the overall accuracy for absolute measurement is approximately 1%. Also, the geometrical factors are studied. (Japan)

57795 (LB/G-3075) CONSTRUCTION OF RESPONSE MATRICES IN γ-SCINTILLATION SPECTROMETRY. Brust, R.; Richter, D. Translated by N. J. Davren (Atomic Energy Research Establishment, Harwell, Eng.), from Nucl. Instrum. Methods; 81: 132-40(1970). 23p. Dep. NTIS (U. S. Sales Only).

Handwritten MS. copy.

An abstract of this paper, prepared from the original language, appeared as NSA 24: 29559. (R.W.R.)

57796 (ORNL-TM-3457) NEUTRON-CAPTURE-GAMMA RAY SPECTRUM CALCULATIONS FOR MATERIALS FOR POSSIBLE USE IN A ^{252}Cf NEUTRON ACTIVATION FACILITY. DeCarlo, V. A.; Arnold, E. D. (Oak Ridge National Lab., Tenn.). Jul 1971. Contract W-7405-eng-26. 31p. Dep. NTIS.

By using the ANISN computer program, neutron-capture-gamma-ray information was obtained for a number of materials, in a fixed arrangement, for use in a ^{252}Cf neutron activation facility. This information will be useful in the selection of materials to minimize gamma spectral interference. It was determined that a system using a source encapsulated in platinum encased in Zircaloy-2, with bismuth as the primary gamma shielding material, produced the lowest number of capture gamma rays and the highest thermal flux. (auth)

57797 CHANNELS ON SURFACES OF Ge(Li)-DIODES AND THEIR INFLUENCE ON X-RAY AND ELECTRON SPECTRA. Baldinger, E.; Haller, E. (Univ., Basel). pp 9-22 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The effects of a channel on the surface of a small Ge(Li) planar detector on the detector properties were investigated. The detector capacitance and the length of the channel were measured. The presence of a surface channel produces a deformation of the electric field resulting in a degradation of the charge collecting efficiency in some parts of the diode. If electrons are irradiated into the intrinsic zone of a Ge(Li) diode, a surface channel will produce a tailing to lower energies in the shape of the electron lines. In γ spectroscopy a surface channel will reduce the active volume of the counter, particularly at low energies; therefore, the full energy peak efficiency decreases toward lower energies. The observed effects appear to be due to adsorbed gases. (R.W.R.)

57798 INFLUENCE OF TRAPPING EFFECTS ON Ge(Li) DETECTOR PERFORMANCE. Henck, R.; Gutknecht, D.; Siffert, P. (CRN, Strasbourg). pp 23-34 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (May 1970). See CONF-700527.

The variation of the trapping cross section with the electric field is studied, and a relation between the charge collection efficiency and the intrinsic detector resolution is obtained. By using this relation, it is possible to predict the peak shape obtained with uniform γ-ray irradiation, if the lifetime (or the drift length) of the carriers is known. Furthermore, a correlation is found, in most cases, between the observed trapping effects and the electron lifetimes measured at low temperature on the starting p-type material by the pulse-decay method. (R.W.R.)

57799 RECENT DEVELOPMENTS OF WELL-TYPE DETECTORS WITH LESS THAN 5 MICRONS DEAD-LAYER. Forcinal, G.; Meuleman, J. (RTC La Radiotechnique-Compelec, Caen, France). pp 62-9 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Work on well-type Ge(Li) spectrometers with thin windows (less than 5μ) is described. Fabrication and thickness measurement of the entrance windows is first discussed. This is followed by an explanation of the fabrication and mounting of the detectors and a presentation of results obtained. A peak-to-valley ratio of 5 in the range of 40 to 100 keV is reported. (R.W.R.)

57800 DETECTOR PROBE FOR ENCAPSULATED Ge(Li)'S DIRECTLY IMMERSED IN LIQUID NITROGEN. Meyer, H.; Heinz, W. (Central Bureau for Nuclear Measurements, Geel, Belg.). pp 101-6 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

A detector probe for γ spectrometry and tests with encapsulated lithium-compensated germanium detectors is described. Detectors are stacked onto a probe, and the arrangement can be immersed directly into liquid nitrogen stored in a standard dewar container. A quick and repetitive assembly is possible with very small probability for a degradation of performance. The probe contains the front end of a charge-sensitive preamplifier, the elements of which are embedded in a solid foam material with low thermal conductivity and a small diffusion coefficient for water vapor. The element temperature within the probe can be adjusted for minimum noise. (auth)

57801 HIGH-RESOLUTION 5000 μ SILICON SURFACE-BARRIER DETECTORS. Klema, E. D. (Tufts Univ., Medford, Mass.); Crawley, G. M.; Garvey, G. T.; Foster, C. C. pp 119-26 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Tests on three 5000-μ Si surface-barrier detectors are described. The results show that 30-MeV protons can be measured with such detectors with an energy resolution of 0.1%. (R.W.R.)

57802 MEASUREMENT OF THE CAPACITANCE CHARACTERISTICS OF LITHIUM-DRIFTED PIN-DIODES MOUNTED TOGETHER WITH A COOLED FET STAGE. Kuehn, E. W.; Schroeder, A. N. F.; Rook, D. A. (Univ., Cologne). pp 127-36 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Measurement of the capacitance of Ge(Li) and Si(Li) detectors is discussed. Circuits suitable for making the measurement and graphs of capacitance as a function of detector bias are given. The appearance of surface channels on the detectors is noted. (R.W.R.)

57803 BACKGROUND MEASUREMENT OF A Ge(Li) DETECTOR APPLICATION TO THE DETERMINATION OF THE ^{76}Ge $\beta\beta$ HALF LIFE. Fiorini, E. (Univ., Milan. INFN, Milan); Pullia, A.; Bertolini, G.; Cappellani, F.; Restelli, G. pp 144-52 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The construction of a low-background Ge(Li) spectrometer, used for the measurement of ^{76}Ge double beta decay [Lett. Nuovo Cim., I; 3: 149(1970)], is described. A tentative interpretation of the various sources of background and their relative contribution is given. (R.W.R.)

57804 DETECTION OF HIGH ENERGY γ-QUANTA WITH A PAIR-SPECTROMETER. Hanle, H. (Johann Wolfgang Goethe-Univ., Frankfurt am Main). pp 153-66 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The use of a pair spectrometer for the detection of high-energy gamma rays is described, and the resulting pulse-height distributions are discussed for several different modes of operation. They show that the use of a pair spectrometer can appreciably improve complex spectra. Transitions of lower intensities can be measured by suppressing the Compton background. The number of peaks is reduced to that of the double-escape peaks. Even the twofold-co-

XUM

incidence mode gives a considerable simplification of the spectra. (R.W.R.)

57805 LARGE WELL-TYPE GeLi DETECTOR FOR ACTIVATION ANALYSIS. Adams, F. (Univ., Ghent). pp 167-73 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

The fabrication and testing of a 60-cm^3, well-type Ge(Li) detector are described. Detection efficiency is excellent, as compared with that for a 3″ × 3″ right cylindrical NaI(Tl) detector and a 20-cm^3 coaxial Ge(Li) detector. Full-energy peak-detection efficiency was essentially independent of the sample position from the bottom of the well to a position 20 mm higher; thus, inaccuracies due to sample-positioning errors are removed. Resolution was 6 keV (fwhm) at 1.332 MeV. A serious drawback is the absorption of low-energy photons by the Ge dead layer. (R.W.R.)

57806 DESIGN AND LIMITATIONS OF A HIGH COUNT RATE TWO PARAMETER SYSTEM WITH A Ge(Li)-DETECTOR. Winter, J. (Central Bureau for Nuclear Measurements, Geel, Belg.). pp 188-2011 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

A two-parameter system used for the measurement of γ-ray spectra of neutron capture resonances is described. The total channel capacity of that system is roughly one million (4096 amplitude channels and 256 time channels for the neutron energy). Special features are rapid recovery after the gamma-flash of the linear accelerator, which overloads the system up to 10^4 times, and the ability to accept very high counting rates without losing events due to pile-up. The principle adopted to meet these requirements is as follows: The pulses from the overload-proof preamplifier are compressed to narrow pulses. Thus, the probability for pile-up is greatly reduced. A linear gate and a condition control unit select the useful events. Afterwards, these pulses are shaped as usual and analyzed in the ADC. As this preselection is made in the fast-pulse domain, high counting rate and overload problems are greatly reduced without losing useful events. Advantages, criteria for optimum design, and limits of this system are discussed in detail. (auth)

57807 EXPERIMENTAL INVESTIGATIONS OF EXOTIC SEMICONDUCTORS FOR NUCLEAR PARTICLE DETECTION. Willig, W. R.; Roth, S. (Siemen AG, Erlanger, Ger.). pp 202-15 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

A report is given on experimental investigations of InSb and PbO nuclear particle detectors. Results on energy resolution and depth of depletion layer are presented for InSb detectors at 78°K. High-temperature application of PbO detectors is discussed. Charge collection in PbO is studied from the detector response to alpha particles. (auth)

57808 SMALL ROD-SHAPED SILICON DETECTORS FOR MEDICAL APPLICATIONS. Glasow, P.; Jaentsch, O. (Siemens AG, Erlangen, Ger.). pp 263-9 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

It is very difficult to stabilize the noise and reverse characteristics of rod-shaped silicon detectors for medical application. They must function well in acids and other solutions without having a dense encapsulation. Therefore, special geometries of the end of the rod and surface protections were developed. Even for monoenergetic particles the detectors have a continuous spectrum, which decreases with increasing channel number. This can be explained theoretically by using an RC delay line as an equivalent circuit. (auth)

57809 ION IMPLANTED NUCLEAR PARTICLE DETECTORS. Sebillotte, Ph.; N'Docko, V. B.; Siffert, P. (CRN, Strasbourg). pp 302-18 of Proceedings of the Symposium on Semiconductor Detectors for Nuclear Radiation. Munich; Technische Universitaet (1970).

From Symposium on semiconductor detectors for nuclear radiation; Munich, Germany (11 May 1970). See CONF-700527.

Nuclear particle detectors made by boron implantation into silicon are described. Implant conditions are reviewed first. Then the electrical characteristics of the implanted crystal are discussed: these include sheet resistivity and effects of starting-material resistivity, doses, crystal orientation, and annealing on I-V characteristics for room-temperature implantation; implantation at 77°K is also briefly considered. The energy resolution and window thickness of the completed detectors are reported. At present, the main advantages of the ion-implanted detector seem to be its stability and the possibility of using classical transistor techniques to assure a better surface control. The performance of these detectors as nuclear particle spectrometers is similar to that of surface-barrier counters. (R.W.R.)

57810 COMPUTER ANALYSIS OF GAMMA-RAY SPECTRA. Tominaga, Hiroshi (Japan Atomic Energy Research Inst., Oarai, Japan). Radioisotopes (Tokyo); 20: No. 2, 93-101(Feb 1971). (In Japanese).

A review on computer analysis of gamma-ray spectra is presented. The review concerns a method to analyze isotopes by comparison with data of the same isotopes of a known amount. The amount of information from measurements of gamma-ray spectra has increased with the development of Ge(Li) detectors, so that computer analysis has become necessary. The first step of the analysis, smoothing and other treatments are applied, then the position and intensity of the gamma peaks are analyzed. The intensity is compared with data of standard sources by measuring the total or partial area of the peaks. The estimation of background intensity is an important problem and the subtraction of curved background is used in some cases. The peak function fitting method is used for complex peaks. Various functions such as the gaussian function and the exponential function and their combination are employed for this purpose. Search for the peaks is necessary before measurement of the peak intensity. The transfer averaging method, the smoothed first derivative method, and the smoothed second derivative method are used to search the peaks. Other mathematical methods are applied to find the peaks effectively. The response function method is employed to analyze the spectra taken by NaI(Tl) detectors. (Japan)

57811 HIGH PURITY GERMANIUM RADIATION DETECTORS. Drummond, W. E. (Stanford Univ., Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 91-100(Apr 1971).

The fabrication and characterization of high-purity-germanium radiation detectors are described. These detectors are n–i–p diodes with a shallow (1.5-μ) diffused junction and a noninjecting metal–semiconductor contact. The germanium has a net acceptor concentration of approximately 7×10^{11} cm^{-3}, and contamination during processing was prevented by using clean procedures and a KCN treatment. Electrical measurements show that with 500 volts of bias these detectors are fully depleted and have a capacitance of approximately 4.5 pF. Detection characteristics are determined from measurements of γ rays and x rays over the energy range from 6 keV to 136 keV. A deviation from linearity of less than ±0.2% was measured. The resolution of the detectors is characterized by an effective Fano factor of 0.12. The average energy expended per created pair was determined to be 2.95 ± 0.02 eV at 90°K. (auth)

57812 PULSED FEEDBACK TECHNIQUES FOR SEMICONDUCTOR DETECTOR RADIATION SPECTROMETERS. Landis, D. A.; Goulding, F. S.; Pehl, R. H.; Walton, J. T. (Univ. of California, Berkeley). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 115-24(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Methods of applying pulsed-charge feedback to the charge-sensitive preamplifiers used with semiconductor detectors are discussed. All have in common the accumulation of radiation-induced charge pulses on a feedback capacitor to produce a voltage ramp at the output of the feedback stage, which is reset at an appropriate point by pulsing a charge feedback path. Advantages of pulsed feedback over the conventional dc feedback techniques are discussed, together with the precautions required to reduce the effect of the large reset pulse on the later electronics. The application of pulsed-light feedback to low-energy x-ray spectrometers is discussed, and results are presented. Some aspects of this system that tend to limit its high-rate performance are also discussed. A brief account of the use of a transistor current-switch feedback system to reduce overload problems in high-energy γ-ray spectrometers is also given. (auth)

57813 MAGNETIC COMPTON SPECTROMETER FOR HIGH INTENSITY PULSED GAMMA RAY ENVIRONMENTS. Kelly, J. G.; Posey, L. D.; Halbleib, J. A. (Sandia Labs., Albuquerque, N. Mex.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 131-41(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A magnetic Compton spectrometer is described which was designed to measure the gamma-ray spectra from distributed, intense pulsed sources in the presence of gamma-ray, electron, and/or neutron backgrounds. It was used to measure spectra of a nuclear device, the Sandia Pulsed Reactor, and the Hermes II flash x-ray machine. A discussion is given of the design features, the data reduction, and the results of the Hermes II measurement. (auth)

57814 PROGRESS IN THE FABRICATION OF γ-RAY DETECTORS FROM HIGH PURITY GERMANIUM. Baertsch, R. D. (General Electric Research and Development Center, Schenectady, N. Y.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 166-9(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A planar detector with a depletion layer width of 8 mm was fabricated from high-purity germanium. A total system resolution of 2.4 keV at 1.33 MeV was obtained with 600 volts bias on this detector. Another detector with a 3-mm-thick depletion region, which was operated at 2000 volts bias, yielded a system resolution of 1.65 keV at 1.33 MeV. Thin-window detectors were fabricated by using a glow discharge of BF_3 or PF_5. This technique has also been used to form ohmic contacts on high-purity germanium. (auth)

57815 CARRIER TRAPPING IN Ge(Li) DETECTORS. Sher, A. H. (National Bureau of Standards, Washington, D. C.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 175-83(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The results of previously published studies relating to the trapping of charge carriers in semiconductor nuclear radiation detectors, including theoretical models and experimental data, are used to construct a more realistic operational model that can be used to describe the trapping process. Specifically, the model is developed for the situation most commonly reported in the literature, that of electron trapping in planar Ge(Li) detectors. The success of the present model is judged on its ability to predict the variation of the peak shape resulting from γ irradiation of a planar Ge(Li) detector as a function of applied bias. Full-energy γ-ray peaks are calculated with digital computation techniques by incorporating the variation of peak amplitude as a function of charge collection efficiency as well as the variation of carrier life-time with applied field into a previously published model. (auth)

57816 DETECTION OF LOW ENERGY X RAYS WITH Si(Li) DETECTORS. Jaklevic, J. M.; Goulding, F. S. (Univ. of California, Berkeley). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 187-91(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The continuing improvement in energy resolution of semiconductor-detector x-ray spectrometers has led to interest in the use of these devices at energies less than 2 keV. This is an energy region of potential analytical interest since the K x rays of several elements of biological and chemical importance occur at these energies. However, the low x-ray fluorescence yield in low-Z elements, combined with the absorption of low-energy x rays due to the entry window of the vacuum chamber and that of the detector, have made work in this energy region impossible with the standard semiconductor-detector x-ray spectrometers. In this work, the x-ray absorption path was reduced to a minimum to permit low-energy x-ray studies of excitation, entry-window thickness, detector linearity, and resolution. Measurements of characteristic K x rays of elements down to and including carbon (277 eV) were performed using electron beam excitation on low-Z targets. (auth)

57817 BARIUM FLUORIDE AS A GAMMA RAY AND CHARGED PARTICLE DETECTOR. Farukhi, M. R.; Swinehart, C. F. (Harshaw Chemical Co., Solon, Ohio). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 200-4(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Barium fluoride has been found to scintillate to gamma rays and alpha and beta particles. The scintillation performance and pertinent physical properties of BaF_2 are described in relation to some of the commercially available scintillators—NaI(Tl), CsI(Na), CsI(Tl) and CaF_2(Eu). The low-solubility, nonhygroscopic nature and a comparable absorption for gamma rays are particular advantages of BaF_2 over the alkali iodide scintillators. Transmission to its fluorescence emission, shorter decay time and a better photoelectric absorption cross section favor BaF_2 over CaF_2 scintillators. The scintillation pulse height of BaF_2, however, is presently lower than that of the other scintillators. The mechanism responsible for scintillation in BaF_2 is not well understood at present. Data seem to indicate that hole-centers may be playing a primary role in the scintillation emission. BaF_2 is usable for many applications that require a high-Z, nonhygroscopic scintillator. (R.W.R.)

57818 SLOW PULSES FROM GERMAINIUM DETECTORS. Sakai, Eiji (Atomic Energy of Canada Ltd., Chalk River, Ont.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 208-18(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Slow pulses from various types of Ge(Li) detectors, viz, a planar, a coaxial, a thin p^+-contact planar, and a "back-to-back" double planar detector, were studied by using a gamma-ray scanning technique and a risetime selector. A large and abrupt increase in the counting rates of the slow pulses were observed when the n^+-i and the i-p boundaries of these detectors were irradiated by a collimated gamma-ray beam. Slow pulses contributed to background counts in the pulse height distributions. Slow pulses from a deeply depleted n^+-p detector made from a high-purity p-type germanium crystal were also investigated. (auth)

57819 IMPROVED LIGHT OUTPUT FROM VERY THIN PLASTIC SCINTILLATOR. Kaiser, W. C. (Argonne National Lab., Ill.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 219-21(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Comparison tests conducted with standard Pilot B scintillator and Pilot B with 10 times the normal concentration of wave shifter show the latter to exhibit an output pulse $\sim 1\frac{1}{2}$ times as large when viewed with an RCA C31000D GaP first dynode photomultiplier tube. These results bear out a conclusion reached after analyzing the results of a previous study of plastic scintillators [Kaiser, W. C. and J. A. M. de Villiers, IEEE Trans., NS-11, No. 3, 29 (June 1964)]. (auth)

57820 SOME OBSERVATIONS ON GERMANIUM γ-RAY SPECTROMETERS MADE FROM HIGH PURITY p-TYPE MATERIAL. Sakai, Eiji; McMath, T. A.; Fowler, I. L. (Atomic Energy of Canada Ltd., Chalk River, Ont.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 228-32(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Some properties of five germanium spectrometers made from two adjacent slices of a crystal of high-purity p-type germanium are described. Techniques used to put contacts on conventional Ge(Li) detectors were used, but found to be somewhat unsatisfactory for the high-purity material. (auth)

57821 LOW POWER CHARGE SENSITIVE AMPLIFICATION AND FAST COINCIDENCE SYSTEM FOR SPACE APPLICATION. Guenther, Godehard A. (Univ. of Alabama, Huntsville); Streeter, Gary. IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 275-81(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A charge-sensitive FET amplification and coincidence system for solid-state detectors and random counting rates of 350,000/sec is described. The fully depleted Si surface-barrier detectors are dc-coupled to the FET input stages of the preamplifiers, which produce pulses of 30 ns risetime with a 100 ns decay constant. The postamplifiers are integrating and differentiating, and generate negative-going bipolar pulses of 1 μs length. The dynamic range goes from 25 mV to 5 volts at a stability of 3% over a temperature range from −30°C to +50°C. With 60 pf input capacity the noise is 38 keV. A set of threshold discriminators rejects noise and strobes the subsequent zero-crossover detectors. The outputs are square pulses, which activate a 40-ns tunnel diode coincidence circuit. The power consumption of the complete system is 150 mW. Miniaturized PC board construction is used for packaging. (auth)

57822 SPECTROMETRIC CHARACTERISTICS OF GERMANIUM DETECTORS WITH RADIATION DEFECTS. Stolyarova, E. L.; Volodin, S. N.; Platov, A. I.; Samedov, V. V. (Inst. of Engineering Physics, Moscow). pp 277-85 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The results of studies on the spectrometric characteristics of a germanium detector based on radiation defects are presented. The valuable properties of detectors of this type are that they can

XUM

be stored at room temperature and repeatedly cooled to 70°K and heated to 300°K. They have a thin dead layer, so that they can be used extensively in the measurement of low-energy gamma rays and characteristic X-rays. The detector was studied in a gamma-spectrometer system with a charge-sensitive low-noise preamplifier. The basic characteristics of the detector are given. The linearity of the spectrometer lies within experimental errors in the energy range investigated, i.e. 122 to 1333 keV. Data are also given from studies on the relationship between photo-contribution and gamma-ray to energy, together with the author's evaluations of the life-time and relative loss of charge carriers. (auth)

57823 COMPARISON AND ANALYSIS OF THE PARAMETERS OF CLINICAL WHOLE-BODY SPECTROMETERS. Fedrorov, G. A.; Konstantinov, I. E.; Slavyagin, P. D.; Moiseev, I. F.; Antonov, V. A. (All-Union Research Inst. for Instrument Making, Moscow). pp 579-90 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The parameters of four types of clinical whole-body spectrometers (eight-crystal spectrometer—four crystals above and four crystals under the patient; two-crystal spectrometer with linear scanning geometry; two-crystal spectrometer with spiral scanning geometry and with a possible termination and without any termination of the forward probe movement at the ends of the phantom) are compared from the point of view of two basic characteristics required of such spectrometers: (1) The spectrometer should have uniform spatial sensitivity, i.e. pulse counts should be independent of isotope localization in the organism; and (2) It should have maximum sensitivity relative to the number of detectors required for meeting the first requirement. An M-20 computer was used for calculating the efficiency of counting the primary gamma radiation from isotropic point sources of ^{125}I, ^{141}Ce, ^{51}Cr, ^{131}I, ^{137}Cs, ^{60}Co, and ^{40}K placed at 13 points of each of the 18 sections (every 10 cm) of a water-filled elliptical cylinder 180 cm in length and with 36 cm and 20 cm axes, for the four above-mentioned measurement geometries. Results were obtained for different measurement geometries. The calculations were verified experimentally by an eight-crystal spectrometer. From an analysis of the results, the optimum measurement geometry for the four types of spectrometers was determined. It is shown that the uniformity of spatial sensitivity can be considerably improved if the entire spectrum of gamma radiation from the phantom is recorded. (auth)

57824 NUTATION NMR STABILIZER FOR BETA-SPECTROMETER MAGNETIC FIELDS. Stakhov, O. V. Izv. Akad. Nauk Kaz. SSR, Ser. Fiz.-Mat.; No. 4, 50-6(Jul-Aug 1969). (In Russian).

A stabilizer, based on the phenomenon of mutation (NMR), for nonhomogeneous magnetic fields of $\pi\sqrt{2}$ beta spectrometers with an equilibrium-orbit radius of 500 mm is described. The schematic diagram of the stabilizer, the design of the thermostatically controlled analyzer, and the variable-volume-field recorder are given. The stabilizer permits the stabilization of nonhomogeneous fields with a high accuracy ($\sim 10^{-5}$), and can be used with slight alterations for field stabilization in spectrometers of other types. (tr-auth)

High Energy Physics Instrumentation

57825 (RPP/H–81) SIMPLE IONIZATION MEASURING DEVICE FOR BUBBLE CHAMBER PICTURES. Bairstow, R.; Brandstetter, A.; Hunt, J. H. (Rutherford High Energy Lab., Chilton (England)). Aug 1971. 12p. Dep. NTIS (U. S. Sales Only).

A small self-contained device for the measurement of ionization in bubble chamber pictures has been developed at the Rutherford High Energy Laboratory. A description of the instrument and results of ionization measurements are presented and the possible use of this instrument as an aid for monitoring bubble chamber exposures is discussed. (auth)

57826 (SJC-T-71-3) OPTICS OF THE 75 cm HYDROGEN BUBBLE CHAMBER. [PART] I. Matur, H.; Nakajima, K.; Yoshimura, Y. (Tokyo Univ. (Japan). Inst. for Nuclear Study). Mar 1971. 25p. (In Japanese). Dep. NTIS (U. S. Sales Only).

The design of an optical system for a 75 cm hydrogen bubble chamber is presented. Three cameras are employed to take stereo photographs. A bright field system is used because of technical problems in making glass for windows and lenses. Three lenses were designed by taking high resolution, small distortion, no movement of pupils, and small diameter into consideration. The lenses were composed of seven glasses, and designed to have a focal length of 74.95 mm and an iris diaphragm of F/8 to F/32. The distortion aberration was less than 0.007% for d line, and the resolution was more than 100 lines/mm. The distortion was measured with Moire fringes, and was less than 0.014%. The measured focal length was 74.70 ± 0.05 mm. The cameras for the bubble chamber are pulsed cameras. Driving of the cameras must be finished within 100 m sec, since two photographs should be taken during one cycle of an accelerator. A xenon gas flash tube was used for a light source. Scotchlite SPR 1042 (Minnesota Mining and Manufacturing) was used for the present purpose. High resolution was required for films, and minicopy film HR (Fuji Film Co.) was used. The resolution was 340 lines/mm. (Japan)

57827 PRESENT STATUS OF AUTOMATIC ANALYSIS OF BUBBLE CHAMBER PHOTOGRAPHS. Yamagata, Taketora (Tokyo Metropolitan Univ.). Oyo Butsuri; 40: No. 4, 348-57 (Apr 1971). (In Japanese).

The present status of automatic analysis of bubble chamber photographs is reviewed. The analysis of bubble chamber photographs has been a serious problem in elementary particle physics, because it was necessary to analyze one million pictures in a year. Several methods of the automatic analysis were developed. HPD (Hough–Powell Device) has been widely used. The speed of the scanning is 400 lines per second, and it takes 6 seconds for scanning one film. Three alternative processes are necessary before the scanning by HPD. One is road guidance which is a method of rough manual digitization of position of vertex and track. The second method is vertex guidance that is a method of rough digitization of the position of vertex only. The third method is zero guidance which means no predigitization, and this method is under development. Spiral readers are also used as well as the HPD. This device scans films spirally from a vertex. The vertex guidance is necessary before the scanning. A device named CAMP (Computer-Aided-Measuring-Projector) which is composed of a rough digitizer and a small computer is also described. Scanning is performed with a slit. Recently, devices using a cathode ray tube have been developed. The motion of spots of these devices is easily controlled at high speeds by a computer. (Japan)

57828 STUDY OF LARGE-AREA, FLAT SCINTILLATION DETECTORS. Ivanenko, V. M.; Moldabaev, E. K. Izv. Akad. Nauk Kaz. SSR, Ser. Fiz.-Mat.; No. 4, 45-9(Jul-Aug 1969). (In Russian).

A study of scintillation detectors 0.25, 0.5, and 1 m^2 in area is reported; they are used in experiments for the study of high-energy nuclear interactions of cosmic rays. The light collection of the scintillation detectors, which use trapezoidal air light pipes of constant cross section, was studied. The average measured pulse-height resolution of the meter scintillation detector is 85%, with the intrinsic scintillator resolution being 16%. The coefficient of the inhomogeneity of light collection, relative to the PM quantity, varies from 12 to 53%. The average measured coefficient of attenuation for the scintillations is equal to 0.015 cm^{-1}. (tr-auth)

57829 SENSITIVITY OF NUCLEAR EMULSION AT VERY LOW TEMPERATURE. Johnson, A. W.; Hebert, C. J. D.; Hebert, J.; Lamarche, J. L. G. (Univ. of Ottawa). Can. J. Phys.; 49: No. 19, 2524-6(1 Oct 1971).

The sensitivity of Ilford G5 emulsion was studied at very low temperature by comparing the grain density of proton tracks recorded at 0.1°K and at room temperature. It is found that the emulsion retains (74 ± 2)% of its room temperature sensitivity when exposed at 0.1°K and that temperature cycling has no noticeable effect on previously recorded tracks. 57830 SPECIFICATION FOR DIRECT-READING PERSONAL DOSEMETERS FOR X- AND GAMMA RADIATION. British Standard 3385 1961. London; British Standards Institution (1961). 8p. Available from American National Standards Institute, New York.

A standard prescribing requirements for the design of personnel quartz-fiber pocket ionization chamber for the measurement of integrated x and gamma radiation exposure doses in roentgens is presented. (W.H.K.)

57831 RADIATION DOSIMETER HAVING SENSITIVE MATERIAL CONTAINING LITHIUM HYDRIDE. **Oberhofer, Martin; Jaspert, Jurgen (to EURATOM).** U. S. Patent 3,577,161. 4 May 1971. Priority date 21 Dec 1966, Netherlands.

A radiation dosimeter based on thermoluminescence is described. The sensitive material in the dosimeter is, at least in part, lithium fluoride, and to the sensitive material is added lithium hydride. (auth)

57832 METHOD FOR READING A THERMOLUMINESCENT DOSIMETER. **McCall, Richard C. (to United States Atomic Energy Commission).** U. S. Patent 3,582,652. 1 Jun 1971. Filed 12 Jan 1970.

A method for reading the exposure of radiation sensitive thermoluminescent material to x-radiation or radiation from a radioactive source is described. The method comprises the steps of very rapidly heating the material to a temperature slightly above the temperature of peak luminescence, evenly maintaining the material at the attained temperature for a period that extends at least to the termination of luminescence of the material, and sensing the total luminescence of the material. (auth)

57833 LUMINESCENCE AND EXOELECTRON DOSIMETRY IN PERSONNEL MONITORING. **Attix, F. H. (Naval Research Lab., Washington, D. C.).** pp 3-15 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The acceptance of luminescence (especially thermoluminescence) dosimeters for routine γ- and β-ray monitoring has been progressing in a number of establishments, and the development of automatic read-out equipment will no doubt accelerate this process. A number of useful dosimeter phosphors are available for this application; however, lithium fluoride continues to be the most widely employed. In the area of neutron dosimetry, luminescent dosimeters have not been so successful, because they are insensitive to fast neutrons. Various methods have been attempted to overcome this deficiency, and these are discussed. It is pointed out that it should be possible to achieve a useful luminescent dosimeter for registering the combined γ-ray + intermediate neutron dose by adjusting the thermal-neutron/γ-ray response ratio. Several recent attempts at achieving a more acceptable fast-neutron response are discussed, including one based on an exoelectron emission dosimeter. (32 references) (auth)

57834 INVESTIGATIONS ON EXOELECTRONS WITH A SPECIAL PROPORTIONAL COUNTER. **Kriks, H. J. (Physikalisch-Technische Bundesanstalt, Brunswick).** pp 17-24 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A proportional counter of pill-box type working with methane as counting gas was developed as a detector for exoelectrons. The mechanical construction of the device allows both optical and thermal stimulation of exoelectrons. The counting properties of the detector were investigated with special emphasis on its suitability for detecting low-energy exoelectrons. The plateau for a ^{63}Ni betasource inside the counter has a rise of about 4% per 100 V over a range of 500 V. The dead-time is less than 2 μs, and the counting rates at a cathode voltage of 3700 V proved to be sufficiently constant even when the temperature at the sample surface was more than 400°C. With this device the thermally stimulated exoelectron emission (TSEE) from beryllium oxide irradiated with ^{60}Co gamma rays has been studied. The results show that it is possible to obtain a response sufficiently proportional to exposure in the range from 2 mR up to 2 R with BeO powder without adding graphite. A mixture of 15% BeO and 85% graphite powder extends the proportionality range to 500 R. Combining BeO exoelectron dosimeters of different BeO contents should give applications in both routine dosimetry and emergency situations. (auth)

57835 NEW EXOELECTRON DOSIMETERS. **Becker, K.; Cheka, J. S.; Crase, K. W.; Gammage, R. B. (Oak Ridge National Lab., Tenn.).** pp 25-36 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Two techniques for preparing highly sensitive, mechanically and chemically resistant, inexpensive and well reproducible detectors based on the thermally stimulated exoelectron emission (TSEE) from small polycrystalline, sintered BeO discs were studied. In one method, the discs are impregnated by controlled thermal diffusion with inert high-melting metals such as Pt, Pd and Au for increasing the electrical conductivity and reducing the work function of the surface. In the second, superior method, the BeO discs are sensitized by heating in air at temperatures up to 1400°C. The high sensitivity is retained during storage in air. Immersion in water reduces the sensitivity, which can be fully restored by re-heating. If proper care is taken, either by protective framing of the detectors or by a special design of the reader, even small doses (<1 mR) can be measured with good reproducibility ($\sigma = 2\%$ to 5%). Fast neutrons can be measured as the response difference between detectors covered with polyethylene and with Teflon. The detection limit is <1 mrad, the energy response satisfactory. (auth)

57836 HIGH-SENSITIVITY THERMALLY STIMULATED EXOELECTRON EMISSION ELEMENT FOR GAMMA DOSIMETERS. **Beskorskii, A. I.; Zhegalina, G. A.; Kuz'min, V. V.; (and others) (All-Union Research Inst. for Instrument Making, Moscow).** pp 37-43 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A new method of dosimetry based on thermally stimulated exoelectron emission is discussed. The design of a series-produced element of the DE-1G type and its basic parameters including slope of the plateau of the counting-rate curve, amplitude characteristic, dead time, reproducibility of readings, scatter of sensitivity in a batch of elements, dose characteristic, fading and energy dependence are described. The technology of producing the exoelectron emitter and the element is briefly described. The construction of the element in the form of a sealed gas-discharge counter made it possible to obtain ±3% reproducibility of readings for a sensitivity of 300 pulses per 1 mR and a background of 0.1 mR. (auth)

57837 SURFACE DOSIMETRY USING THERMOLUMINESCENT DISCS. **Gibson, J. A. B.; Marshall, M.; Docherty, J. (United Kingdom Atomic Energy Authority, Harwell, Eng.).** pp 45-57 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Lithium fluoride loaded into Teflon discs of thickness 9 mg$\cdot$cm^{-2} forms a very convenient dosimeter for measuring surface dose rate from beta and gamma radiation. Stacks of thin dosimeters have been used in many special experiments, for example, measurement of the dose to the fingers from ^{82}Br in silica glass vials, and the maximum gamma-ray dose estimation from nuclear heat sources using ^{238}Pu. In both cases the calculated dose agreed with the extrapolated surface dose from the TLD stacks. This has confirmed that theoretical methods can be used to give an early estimate of overexposure, particularly where the incident cannot be reproduced experimentally. (auth)

57838 IAEA INTERNATIONAL GLASS DOSIMETRY INTERCOMPARISON, 1970. **Dorofeev, G. A.; Somasundaram, S. (International Atomic Energy Agency, Vienna).** pp 59-66 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Assessments of the reliability and accuracy of measurement of gamma radiation fields used for calibration purposes were initiated by mailing radiophotoluminescent glass dosimeters to twenty Member States' laboratories; after irradiation these were returned to IAEA for measurement. It was found that in some laboratories the accuracy of measurement is outside the limits prescribed in the ICRP Recommendations. This experiment helped the laboratories to check and correct their calibration procedures, and the work will be extended to all IAEA Member States interested in keeping their secondary standard calibrations at an internationally acceptable accuracy. (auth)

57839 SEALED THERMOLUMINESCENT DOSIMETER EMPLOYING R. F. HEATING FOR ROUTINE INDIVIDUAL MONITORING. **Brunskill, R. T. (United Kingdom Atomic Energy Authority, Sellafield, Eng.); Langmead, W. A.** pp 67-76 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

XUM

The indications for thermoluminescence dosimetry in various types of individual monitoring are reviewed. It is concluded that TLD is the system of choice for many applications provided that a simple dosimeter design is available that is capable of automated dose read-out. A two-element dosimeter is described incorporating graphite trays contained in a Tufnol and Teflon body. The thermoluminescent material, at present lithium borate or fluoride, is attached to the graphite trays in a solid matrix of non-luminescent adhesive, and is covered by a window of FEP film. Read-out is achieved by eddy current heating of the graphite by R.F. energy fed to a small water-cooled coil below the dosimeter, thus making unnecessary any handling of the TL material. The response characteristics of the dosimeter to various radiation types and energies are given. Proposals for a dosimeter system providing simultaneous read-out of surface dose and dose from the penetrating component of the radiation are made. (auth)

57840 DEVELOPMENT OF THERMOLUMINESCENCE DOSIMETRY SYSTEMS AT AEE WINFRITH. Johns, T. F.; Peabody, C. O.; Preston, H. E.; Perry, K. E. G. (Atomic Energy Establishment, Winfrith, Eng.). pp 77-90 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Operational experience with thermoluminescence dosimeters at AEE Winfrith has shown that technically thermoluminescence dosimetry is an acceptable method for the measurement of doses to the trunk of the body. Details are given of the dosimeters which have been used and of the results which have been obtained. While the devices which have so far been used are satisfactory for use on small or medium scale, they are not suitable for use on a very large scale because of difficulties associated with the data handling. A more sophisticated badge is being developed which is intended to overcome these difficulties. It is hoped that this might ultimately prove to be an acceptable alternative to (or even a replacement for) the film badge, for use on a very large scale. Details are given of progress made in overcoming some of the difficulties still associated with this concept. (auth)

57841 NEW THERMOLUMINESCENCE DOSIMETER OF HIGH SENSITIVITY USING A MAGNESIUM SILICATE PHOSPHOR. Hashizume, T. (National Inst. of Radiological Sciences, Chiba, Japan); Kato, Y.; Nakajima, T.; (and others). pp 91-100 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The thermoluminescence dosimeter (TLD) is now widely used for dosimetry of various kinds of radiation. The phosphors at present available for TLD are classified into two groups, one of which, for instance LiF, is excellent in tissue equivalence, but is inferior in sensitivity. The other group possesses high sensitivity, but is much inferior in tissue equivalence. Examples are $CaSO_4$: Mn(Dy) and CaF_2: Mn. Therefore it was decided to develop a new phosphor which meets the requirements of both tissue equivalence and sensitivity. This phosphor has the composition Mg_2SiO_4 and includes a small amount of Tb^{3+} as activator. Its various properties as a dosimeter and other physical aspects are described. Most experiments were carried out using glass tubes of 2.0 mm in diameter and 10 mm in length in which the phosphor was sealed under a rare gas. In some cases dosimeter elements embedded in plastics were also used. Outstanding characteristics are as follows: (1) The dosimeter is responsive to X and gamma rays over a wide range of dose (0.1 mR to 10^4 R). The sensitivity is 100 times that of LiF (a commercial product); (2) The energy dependence is much less than that of $CaSO_4$: Mn(Dy) or CaF_2: Mn, which belong to the group of high-sensitivity phosphors. For instance, the sensitivity to 38 keV (eff.) X-rays is four times that for ^{60}Co gamma rays. Moreover, this dependence is easily reduced to less than 1.3 by means of a tin filter; (3) The effective atomic number is 11.0; (4) The glow curve is simply shaped peaking at about 200°C. The fading after keeping for 60 days at room temperature is less than 3%. It is concluded that this phosphor, with its distinctive properties, will prove of value in dosimetry. (auth)

57842 COMBINED LITHIUM BORATE AND LITHIUM FLUORIDE THERMOLUMINESCENCE DOSIMETER FOR ROUTINE PERSONAL MONITORING. Christensen, P. (Danish Atomic Energy Commission Research Establishment, Risoe). pp 101-12 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Hot-pressed, 25 mg lithium-7 fluoride dosimeters (Harshaw) and sintered, 25 mg lithium borate dosimeters were compared and studied for application to routine personal monitoring. The lithium borate phosphor was prepared at Risö from lithium tetraborate with small additions of manganese and quartz and it was formed into tablets by means of an automatic tabletting machine. The sensitivity ratio LiF/$Li_2B_4O_7$: Mn, Si was measured to be 3/1 with an Sb/Cs photomultiplier tube. The study of the two dosimeter types covered fading, annealing requirements, energy dependence on photon and beta radiation, re-use, neutron sensitivity, sensitivity to light, precision of low-dose measurements, etc. Plastic capsules each containing two ^{7}LiF and two $Li_2B_4O_7$: Mn, Si dosimeters were worn as personal dosimeters, in addition to their film dosimeters, by people working in reactor facilities and other areas. Good agreement between the two types of TL dosimeters was obtained for dose measurements in neutron-free areas. In reactor buildings a small overdose effect caused by neutrons was shown by the borate. The data showed poor agreement between TL and film dosimeters. A personnel dosimetry system consisting of two $Li_2B_4O_7$: Mn dosimeters for normal routine beta and gamma monitoring and one ^{7}LiF dosimeter used as a long-term dosimeter and as a safeguard against false readings due to thermal neutrons seems to make the most of the advantages of both $Li_2B_4O_7$: Mn (low production cost, no annealing requirements after the read-out process) and ^{7}LiF(no fading, good accuracy, low sensitivity to thermal neutrons). The three dosimeters were assembled in a badge intended for routine personal monitoring, and the system was investigated for its energy and angular dependence with photon and beta radiation. (auth)

57843 READ-OUT INSTRUMENTS FOR SOLID THERMOLUMINESCENCE DOSIMETERS, USING HOT NITROGEN GAS AS THE HEATING MEDIUM. Boetter-Jensen, L. (Danish Atomic Energy Commission Research Establishment, Risoe). pp 113-24 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Two thermoluminescence dosimeter (TLD) readers with hot nitrogen gas as the heating medium were designed for measuring solid TLDs. The main advantages of nitrogen heating over traditional heating systems are: (1) a minimum of black-body emission on account of a fixed gas temperature and the absence of mechanical heating elements; (2) a very reproducible heating procedure as the dosimeters are completely surrounded by the heating medium; and (3) a convenient feeding procedure permitting a large number of dosimeters to be measured in a short time. One reader was designed for measuring solid dosimeters of different shapes and sizes. The other was designed to measure small dosimeters only, e.g. Harshaw Chemical Company's 25 mg hot-pressed LiF dosimeters (3 × 3 × 0.8 mm). The design of the read-out chambers, the dosimeter feeding system and the gas temperature control arrangement are described. Based on one year's operational experience, the performance of the hot-nitrogen read-out technique is discussed. Measurements were carried out to demonstrate the advantages of nitrogen heating, and investigations on the proper adjustment of gas flow and gas temperature were made in order to achieve maximum efficiency and economy. The TL equipment incorporates instrumentation for automatic print-out of the results on a Teletype printer and punched tape for data processing in a computer. Furthermore an automatic sample changer facility is planned for use with a TLD badge containing four dosimeters (LiF and $Li_2B_4O_7$: Mn, Si) marked with a binary identification code. The prototype of the badge is discussed. TL equipment with nitrogen gas heating was used at Risö for eight months for personnel dosimetry, environmental monitoring and other routine measurements. It proved to be very reliable and, moreover, the read-out procedure was very convenient. (auth)

57844 EFFECTS OF RESIDUAL THERMOLUMINESCENCE IN FLUORITE AND LITHIUM FLUORIDE THERMOLUMINESCENT DOSIMETERS. Sunta, C. M.; Kathuria, S. P. (Bhabha Atomic Research Centre, Bombay). pp 125-33 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Natural CaF_2 (fluorite) thermoluminescent dosimetry (TLD) phosphor has five main glow peaks from room temperature to 600°C. Normal reading of dosimeter does not require heating above about 300°C, which therefore leaves the high temperature glow peaks unaffected. This unreleased part of the glow curve is called residual thermoluminescence (RTL). The effect of RTL on sensitivity and linearity is studied. Quantitative measurements are done for gamma exposure sensitivity as a function of RTL. Different magnitudes of RTL were built up by giving suitable reactivating gamma exposures after heating the sample at 600°C to completely release the natural TL. It is found that gamma exposure sensitivity as well as RTL are maximum with reactivating exposures of about 10^5 R. It is seen that gamma sensitivity is about 2.5 times more in a sample with saturated RTL than in that with no RTL. However, the linearity of latter type extends to about 3.5 times higher exposures than in former. A TLD grade fresh natural fluorite sample when heated at 400°C provides a phosphor with saturated RTL and that heated at 600°C gives one with no RTL. The former is more suitable for low radiation measurements and the latter for high levels. Presence of high temperature glow peaks is shown also in LiF TLD phosphors. Importance of RTL peaks in determining the pre-exposure annealing temperature is indicated. It is shown that the effects of RTL are similar in fluorite and LiF TLD phosphors. (auth)

57845 THERMOLUMINESCENCE DOSIMETRY STUDIES AT THE PHILIPPINE ATOMIC RESEARCH CENTER. Bustamante, Norma T.; Bartolome, Z. M. (Philippine Atomic Research Centre, Manila). pp 135-44 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Thermoluminescence dosimetry studies have been initiated at the Philippine Atomic Research Center of the Philippine Atomic Energy Commission. A recalibration of the equipment indicates a divergence from supplied calibration curves, especially with regard to the dark current. Operating currents and heating temperatures also show a statistical uncertainty of approximately 7%. Gamma-dose calibrations were undertaken using a ^{60}Co gamma garden previously mapped with an R-meter and chemical dosimeters. Neutron dose calibrations have been attempted using the Philippine research reactor. Some isodose curves in a dry gamma room from a 20,000 Ci ^{60}Co source inside the PRR-I reactor pool are presented. Both unannealed LiF and annealed LiF were studied. (auth)

57846 SOME NEW DEVELOPMENTS IN DOSIMETRIC DETECTORS. Ivanov, V. I. (Inst. of Engineering Physics, Moscow). pp 145-8 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A definition of the category of dosimetric detectors and the principal dosimetric quantities are given. Some new developments in these detectors are reviewed. There is a description of a calorimetric method developed in the USSR for the simultaneous determination of composition and dose-rate in the case of mixed gamma-neutron radiation which uses a single calorimetric substance. The merits of a quartz detector are indicated, and the use of direct-charge detectors for dosimetric purposes are discussed. Also, the possibility of using a solution of glucose in water for in-pile dosimetry is mentioned. (auth)

57847 NEW HIGH-SENSITIVITY THERMOLUMINESCENT DOSIMETER FOR SHORT-TERM PERSONNEL DOSIMETRY. Webb, G. A. M. (Teledyne Isotopes, Westwood, N. J.). pp 149-57 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A new dosimeter is described which is capable of dose measurement down to sufficiently low levels for personnel to be monitored on a daily or hourly basis if required. However, unlike other low-level dosimeters previously in use, the fading of the stored signal is small enough for this effect to be neglected in routine use. Applications of the new dosimeter include the assessment of doses received by visitors to a nuclear site before they have left the site boundary with very much greater accuracy and reliability than is possible using conventional condensor chambers (Q.F.E.'s). The new dosimeter consists of a dispersion of calcium sulphate: dysprosium thermoluminescent dosimetry phosphor in Teflon (PTFE). The resulting dosimeter can detect doses of less than 1 mrad and has acceptable fading of the stored signal at environmental temperatures. Data are presented on the precision of the dosimeter at various dose levels, the linearity of the response with dose, the fading of the stored signal as a function of time and temperature, and the sensitivity to natural and artificial light levels. An installation is described suitable for use by unskilled personnel which would permit monitoring of visitors to a nuclear site or a nuclear area. The main feature of the installation is the capability to immediately measure actual doses received down to meaningful levels for an exposure of only a few hours at low dose levels. (auth)

57848 LiF RADIOTHERMOLIMINESCENT DOSIMETERS WHICH CAN BE REUSED WITHOUT REGENERATION. Portal, G.; Bermann, F.; Blanchard, Ph. (CEA, Fontenay-aux-Roses, France). pp 159-72 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The lithium fluoride now available commercially possesses very valuable properties for radiological safety measurements and it would be of interest to use it for routine measurements. Its use does, however, give rise to problems, firstly due to the instability of the traps located close to the surface and secondly as the material has to be regenerated after each reading. A process has been developed for producing lithium fluoride which is free of this defect and which can be reused a considerable number of times without any appreciable alteration in its properties. The sintering procedure developed for economic production on an industrial scale is described and the essential characteristics are given. (auth)

57849 SENSITIVE ELEMENT FOR RADIOTHERMOLUMINESCENT DOSIMETERS FOR GAMMA AND NEUTRON RADIATIONS. Kuz'min, V. V.; Mysev, I. P.; Sokolov, A. D. (All-Union Research Inst. for Instrument Making, Moscow). pp 173-9 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Methods of measuring the equivalent dose of mixed gamma and neutron radiation based on the use of radiothermoluminophors which exhibit high sensitivity in the recording of heavy charged particles are described. The sensitive element of a dosimeter for making such measurements is designed in the form of a disperse system consisting of a calcium sulfide luminophor and heat-resistant hydrogenous base. The results of measurements of the basic dosimetric parameters of the element are given: Sensitivity to gamma rays and neutrons as a function of luminophor concentration; The standard deviation of sensitivity in a batch of elements with luminophor concentration of 300 mg/cm^3 is ±7.4%; The dose characteristic is linear in the equivalent dose range from 50 mrem to 5 krem; Sensitivity of the element to X-radiation with an effective energy of 40 keV is fifteen times higher than its sensitivity to the gamma radiation of ^{60}Co, but the energy dependence obtained with an 0.64 mm lead filter does not exceed ±20% in the 1000 keV-1.25 MeV energy range; Dependence of the sensitivity of the element to 1 rem equivalent for measurements in the 50 keV-4.5 MeV neutron energy range. The tests carried out with the elements confirm that the method can be used extensively for measuring the dose of mixed gamma and neutron radiations in the case of chronic exposure or severe radiation injury. (auth)

57850 DOSIMETRIC CHARACTERISTICS OF SILICON DETECTORS FOR GAMMA RADIATION. Stolyarova, E. L.; Volodin, S. N.; Samedov, V. V.; Frolov, S. G. (Moscow Engineering Physics Inst.). pp 269-76 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Silicon semiconductor detectors possess properties which are very advantageous in dosimetry-high sensitivity per unit volume, fast action, low bias voltage, high mechanical strength, low sensitivity to magnetic fields, sufficient radiation stability, compactness and light weight. The results of studies on the dosimetric characteristics of silicon diffusion drifted detectors for gamma rays are given. The studies were carried out in a gamma-spectrometer system and on a model of the dosimeter, in which a discriminator was used in order to cut off the noise of the detector-amplifier system. Data are given on energy dependence and on the effect of rectifier filters and discriminator level on energy dependence. It is concluded from the experiments that detectors of this type can be used in gamma dosimetry in the 0.1 to 1.33 MeV energy range and in a wide range of dose rates. (auth)

57851 DETECTOR FOR THE MEASUREMENT OF DOSE DISTRIBUTIONS AT A BONE-TISSUE INTERFACE. Poston, J. W. (Oak Ridge National Lab., Tenn.). pp 299-310 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Radiation detectors are described which facilitate the measurement of dose distributions at a bone-tissue interface. These small extrapolation-ionization chambers allow the measurements of dose distributions at depths in tissue-equivalent phantoms, a significant improvement over dosimeters of this general type. Such measurements allow a more accurate assessment of the importance of this interface in the establishment of external radiation exposure standards. Detector characteristics, such as saturation voltage as a function of electrode spacing, directional response of the chambers, and effects of change in collecting electrode area, are discussed. A method for measuring ionization currents produced in these chambers at large distances from the point of measurement is presented. Results of measurements in a tissue-equivalent phantom are presented for neutrons from several isotopic sources, i.e., AmB, AmBe, and PuBe. Dose distributions from a 14 MeV neutron source are given also. The significance of these results in relation to theoretical studies and the present exposure standards is discussed. (auth)

57852 DOSIMETRIC APPLICATIONS OF ELECTRONIC PARAMAGNETIC RESONANCE MEASUREMENTS OF FREE RADICALS FORMED IN AMINO ACIDS: CONSTRUCTION OF A TISSUE-EQUIVALENT DOSIMETER BASED ON ALANINE. Bermann, F.; De Choudens, H.; Descours, S. (Commissariat a l'Energie Atomique, France). pp 311-25 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

In the case of amino acids, rupture of the molecules due to the action of radiation is found to produce free radicals. The number of these radicals can be measured by means of an electronic paramagnetic resonance spectrometer and this number is proportional to the dose absorbed. Alanine has been used for this purpose since it possesses this property over a wide dose range (from 10 to 5×10^6 rads). The following points are studied: (a) Pre-irradiation effect in non-irradiated alanine: this dose limits the minimum measurable dose to approximately 10 rads. The origin of this dose and means of reducing it have been studied; (b) Energy response of the alanine: by virtue of the close similarity of its composition to that of tissue, this dosimeter has a good energy response for gamma radiations; the loss of efficiency at low energies can be corrected by the addition of a higher Z material (Ba or Ca); (c) Response to neutrons: with neutrons the radical yield is lower than in the case of gamma radiation, although this yield can be increased by adding a hydrogenated substance (paraffin); and (d) Construction of a dosimeter in pellet form: the addition of paraffin improves the response to neutrons and enables moulded pellets of the mixture to be produced. These are easier to use than alanine in powder form and the dosimeters can be produced in any desired form. (auth)

57853 STUDY OF A TISSUE-EQUIVALENT SPHERICAL PROPORTIONAL COUNTER. Dmitrievskii, I. M.; Lysak, Yu. D.; Frolov, V. V. (Inst. of Engineering Physics, Moscow). pp 335-42 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The results of a study on the properties of a Rossi-type proportional counter are presented and it is proposed that they be used as a basis for a new design, characterized by both simplicity and reliability. The conditions under which the counter can be used for measuring dose spectra in terms of LET are considered. A number of new and simple methods of processing recorded spectra and determining the effective value of the quality coefficient are proposed; the error of the results is evaluated. (auth)

57854 NEUTRON DOSE ESTIMATION USING A NATURAL URANIUM FISSION FRAGMENT TRACK PERSONNEL DOSIMETER. Gomaa, M. A. Hassib, G. (Atomic Energy Establishment, Cairo). pp 343-7 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The idea of using a natural uranium fission fragment track dosimeter, in the neutron field of thermal, intermediate and fast neutrons in air, has recently been introduced. The system can be used for thermal neutron dose estimation as well as intermediate plus fast neutron dose estimation if the spectrum and the percentage contribution of each neutron group is known. Feasibility of the use of such dosimeters when they are worn by radiation workers is investigated. Detailed study of the system shows the possibility of differentiating between doses received from fast, intermediate and thermal neutrons if one takes into account reflection from the body of thermal, intermediate and fast neutrons. (auth)

57855 APPLICABILITY OF TRACK DETECTORS IN NEUTRON DOSIMETRY. Burger, G.; Gruenauer, F.; Paretzke, H. (Institut fuer Strahlenschutz, Neuherberg, Ger.). pp 349-58 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

In spite of evident advantages in comparison with nuclear track film, the non-photographic track detectors have not yet found a wide application in practical dosimetry. This was partially due to the complicated methods of track counting with microscopes, which can be avoided by using spark-counters of the "Cross" type. A suitable improved counter is discussed and experience gained in its practical use is reported. The data refer to the reliability of the counting system, to the detector foils used and their dependence on environmental conditions. For some fission foils, the effective dose responses for certain calibration spectra and various assumed leakage spectra have been calculated and, in part, measured. Some theoretical aspects of using different neutron conversion reactions, which affect the dosimetric information obtained, are discussed. (auth)

57856 SETTING-UP OF A NEUTRON DOSIMETER USING IONOGRAPHIC TRACKS IN AN INSULATING SOLID. Carfi, N.; Dugnani Lonati, R.; Mangialajo, M. (Centro Informazioni Studi Esperienze, Milan). pp 359-63 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The use of dielectrics such as mica, glasses and plastic materials for charged particle track recording has been developed in the past years; track recording of fission fragments produced in fissile materials under neutron irradiation is particularly interesting. The method has not as yet been applied to neutron dosimetry owing to the difficulties of track observation and counting using optical microscopes. A method has recently been proposed which results in markedly reduced counting times by electronic counting of the electric discharges between two electrodes through the dielectric which was perforated by the fission fragments. The reasons for adopting this new technique to set-up a neutron dosimeter are: (a) economic advantages, since a rather simple electronic instrumentation will give a reading of the dosimeter, preparation of which can be carried out immediately and at a modest cost; (b) fast reading, since the response can be obtained in less than two hours from irradiation; and (c) dosimetric advantages owing to the lack of fading and insensitivity to β or γ radiations. The method adopted and the equipment used to set up the dosimeter are described. Results are reported and briefly discussed. (auth)

57857 DEVELOPMENT OF NEW NEUTRON DETECTORS FOR ACCIDENT DOSIMETRY. Piesch, E. (Kernforschungszentrum, Karlsruhe, Ger.). pp 399-424 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

New detectors and measuring techniques are proposed to improve the assessment of individual doses in a criticality accident. The aim was to reduce the number of detectors in the conventional detector combinations, to use sensitive activation reactions and to measure the dose of intermediate and fast neutrons directly. The proposed neutron detectors for the dosimeter combination are: (a) Arsenic, to detect slow and intermediate neutrons up to 1 MeV by the $^{75}As(n,\gamma)^{76}As$ reaction (half-life of ^{76}As is 26.4 h); (b) Phosphorus, to detect fast neutrons above a threshold of 2 MeV by the $^{31}P(n,p)^{31}Si$ reaction (half-life of ^{31}Si is 2.6 h), and slow neutrons by the $^{31}P(n,\gamma)^{32}P$ reaction (half-life of ^{32}P is 14 d); (d) A polycarbonate detector (Makrofol E) as a nuclear track detector to detect fast neutrons above a threshold of 0.5 MeV by elastic scattering and (n,α) reactions in carbon and oxygen. The β-activity of ^{76}As, ^{31}Si and ^{32}P can be measured directly in As_2S_3 glass and in phosphate glass by means of the β-induced Cherenkov effect. It uses a liquid scintillation counter set up as for tritium measurements. The calibration of the detectors was performed by calculations of the detector sensitivity for different neutron spectra and by irradiation with different neutron sources at different criticality installations. After an accident a first estimation of the neutron dose is obtained by a β-counting of the arsenic phosphate glass, which indicates the surface adsorbed dose or the total neutron fluence directly. It is energy independent over the range of intermediate and fast neutrons. (auth)

57858 CALCULATIONS OF DOSE FRACTIONS OF SLOW, INTERMEDIATE, AND FAST NEUTRONS BEHIND DIFFERENT SHIELDS, AS WELL AS READINGS OF SELECTED DOSIMETERS. Makra, S.; Bekes, E. (Central Research Inst. for Physics, Budapest). pp 425-33 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The percentage doses of slow, intermediate and fast neutrons were determined for a fission source shielded by materials of different composition and thicknesses. Water, polythene, iron, concrete, concrete + iron, and concrete + boron materials, and thicknesses ranging from 5 cm to 200 cm were considered. Making use of these results one can estimate the percentage dose measured by, and the correction factors to be applied for different dosimeters. A more sophisticated method of evaluating the reading is to multiply the response function by the spectra values and to integrate over the energy range in question. Based upon these calculations, readings are presented for several dosimeters and results are compared. Results show the great importance of intermediate energy neutrons. (auth)

57859 ENERGY CALIBRATION OF DOSIMETERS FOR GAMMA AND X-RAYS. Drexler, G.; Gossrau, M. (Institut fuer Strahlenschutz, Neuherberg, Ger.). pp 477-84 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The evaluation of energy dependence of health physics instrumentation, especially for low-energy radiation, is of great interest. If the exact knowledge of the response of an instrument as a function of photon energy is needed, sources of monoenergetic radiation are required. Since, in the energy range considered, a suitable set of nuclides is not available and beams of fluorescence X-rays, limited in energy to about 100 keV, are difficult to realize in practice at a sufficient dose rate, the only method is to modify the heterogeneous output of an X-ray machine by filtration. The result of a calibration of an instrument strongly depends on the spectral distribution of the beam, and this makes it necessary to use well-defined radiation for this purpose. Defining an "effective energy" (E_{eff}) is not sufficient to characterize the beam. This led to the establishment, for the energy range 40 to 300 keV, of a set of nine radiation qualities, which have the advantage of being reproducible and having a similar spectral dose distribution, making detailed description of the properties of the calibration beam possible. To illustrate the influence of the spectral distribution, the response of several instruments has been compared for radiations having the same mean energy. From the results it can be seen that only a knowledge of the photon spectra gives enough information to interpret the deviations in the various response functions. (auth)

57860 MAINTENANCE OF ELECTRON EQUILIBRIUM IN THE CALIBRATION OF DOSIMETERS IN GAMMA RADIATION BEAMS. Kostyleva, Yu. G.; Mysev, I. P. (All-Union Research Inst. for Instrument Making, Moscow). pp 485-94 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The effect of calibrating the gamma radiation of a source on the maintenance of electron equilibrium and observance of the inverse-square law in the calibration of dosimeters is considered. The expression for an absorbed dose in air on the beam axis, its difference from an exposure dose and the detector readings are investigated as a function of various factors: measurement geometry (distance from source, beam diameter), photon energy and detector-wall thickness. It is shown that for a given geometry this difference and the non-observance of the inverse-square law can lead to considerable errors in the calibration of a detector, and the conditions under which such errors can be neglected are determined. A relationship between the readings of normal chambers and the exposure dose was found. The non-uniformity in the distribution of an absorbed dose in air and the effect of this non-uniformity on errors in the calibration of dosimeters are considered as a function of the above-mentioned factors. The agreement between the calculated and experimental data is discussed. (auth)

57861 DOSIMETRIC CHARACTERISTICS OF A TEFLON-CARBON MIXTURE FOR THE CONSTRUCTION OF CAVITY CHAMBERS FOR MEASUREMENT OF ABSORBED DOSE IN THE AIR. Simoen, J. P.; Sklavenitis, L.; Troesch, G.; Pages, L. (CEA, Saclay, France). pp 567-78 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The theoretical calculation of the dose absorbed in air, based on dose measurements in a cavity within a given material, provides a means of determining the required correction factor and the conditions under which one material will be equivalent to another from the dosimetric point of view. A comparison of the materials currently in use for the construction of ionization chambers, such as graphite, nylon, etc. with Teflon-carbon, shows the latter to be an excellent air-equivalent material and demonstrates its value for the construction of cavity-type ionization chambers. (auth)

57862 DOSIMETRY OF X-RAYS, GAMMA-RAYS, AND NEUTRONS WITH A FERROUS SULFATE SOLUTION. Antoku, Shigetoshi; Sunayashiki, Tadashi (Hiroshima Univ.). Hiroshima Daigaku Genbaku Hoshano Igaku Kenkyusho Nenpo; No. 10, 27-31(May 1969). (In Japanese).

Radiation doses from x-rays (180 kVp, HVL: 1.18 mmCu), γ-rays (Co-60) and neutrons (T, d reaction, 14 MeV) were measured using a ferrous sulfate dosimeter (Fricke dosimeter) and results were compared with earlier ones. The chemical yield per unit absorbed energy (G-value) used were 15.2 for x-rays and 15.6 for γ-rays. Neutron doses were calculated for the two G-values—10.5 and 11.5 for 14 MeV neutrons—which have appeared in the literature. Present dose measurements for Co-60 γ-rays were 2.7 percent higher than those by a ferrous sulfate dosimeter in 1963 calculated using 5.263 years as a half-life of Co-60. One-third of this difference resulted from the different rad conversion factors according to ICRU Tables. Errors in half life and chemical determinations account for the remaining two-thirds of the discrepancy. X-ray dose was previously monitored mainly with an integrator of the Radocon dosimeter, probe #601. Results with chemical dosimeter in this study were 6.0 percent lower than those obtained with the Radocon. Neutron doses have been monitored with a plastic scintillator and by the activation method of the $^{32}S(n,p)^{32}P$ reaction. There is a ten percent difference between the two reported G-values and there are no reasonable data by which this can be corrected. Therefore no conclusions could be made concerning the ferrous sulfate dosimeter. The G-value of the dosimeter for 14 MeV neutrons was calculated to be 10.4, based on the scintillation method and 10.8 according to the activation method. Dose readings of the ferrous sulfate dosimeter in this study agreed with those of the standard dosimeter used for the intercomparison of Co-60 γ-rays in Japan. (auth) (Japan)

57863 (CONF-711002-, pp 307-20) TARGET THICKNESS AND UNIFORMITY MEASUREMENTS USING CHARGED PARTICLES. Adair, H. L. (Oak Ridge National Lab., Tenn.). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

The use of alpha particles and fission fragments for measuring target thickness and uniformity of samples varying in areal density from a few $\mu g/cm^2$ to several mg/cm^2 is discussed. Since the accuracy of this technique is limited by the accuracy of the stopping power data, stopping power data for several materials have been determined which should increase the accuracy for these materials to ±7% or better. Beta particle absorption techniques have been applied to target uniformity measurements for those samples whose thicknesses exceed the range of the alpha particles and fission fragments. (W.H.K.)

57864 (INS-TL-112) ALPHA-RAY THICKNESS GAUGE. 2. Nonaka, Itaru; Sugai, Isao (Tokyo Univ. (Japan). Inst. for Nuclear

XUM

Study). 8 Jul 1971. 11p. (In Japanese). Dep. NTIS (U. S. Sales Only).

The α-ray thickness gage described in INS-TL-110, (1970) was improved. A new ^{241}Am source of 1.03 μCi was prepared instead of the old one of 0.1 μCi. The effective strength of the α-rays was improved as high as about 20 times that of the old one, and the accuracies of measurements were much improved. A counting rate meter was tested to be used in this α-ray thickness gauge. It was very effective in locating the positions of the ends of the residual ranges. The corrections for the differences of the temperatures between the measurements of samples and of air are discussed. (auth) (Japan)

57865 (NP-18941) MEASUREMENT OF THICKNESSES OF VARIOUS MATERIALS USING Si(Li) AND SURFACE BARRIER DETECTORS. Perez Medina Ollivary, Victor (Universidad Nacional Autonoma de Mexico, Mexico City. Facultad de Ciencias). 1971. 82p. (In Spanish). Dep. NTIS (U. S. Sales Only). Thesis.

The various types of devices used in the measurement of thickness and uniformity are described. The nuclear detector types and their properties are then discussed. Surface-barrier semiconductor and Si(Li) detectors are emphasized. The results obtainable with each type are discussed. The experimental methods used in testing the characteristics of surface barrier and Si(Li) detectors as thickness measuring devices are described. A device for automatically obtaining these measurements and using transistors is discussed. Results obtained for mylar and Al foils are reported. (J.S.R.)

57866 (SC-RR-710450) DETECTION OF HIGH EXPLOSIVES BY CAPTURE GAMMA-RAY TECHNIQUES. Powell, J. E.; Matthews, J. W. (Sandia Labs., Albuquerque, N. Mex.). Aug 1971. 56p. Dep. NTIS.

A series of steady-state experiments was carried out to study the feasibility of using the ^{14}N(n,γ)^{15}N reaction for the detection of land mines. Background effects from inelastic gamma rays were studied by using 14 MeV and fission neutron sources. Other aspects of the technique such as detector response to high energy gamma rays, energy spectra of capture gamma rays from soil and high explosive (HE) samples, and signal-to-background (from capture gamma rays emitted from the soil) ratios were also studied. The experiments showed that because of inelastic gamma rays and fast neutron backgrounds a pulsed source and fast timing procedures were required for a practical mine detector. Because of the pulse pile-up problem, a segmented high Z loaded organic scintillator seems to be the only practical detector. (auth)

57867 NEW RADIOMETRIC APPARATUS FOR PROSPECTING RADIOACTIVE ORES. Ovchinnikov, A. K.; Khromov, Yu. V.; Fomin, A. V. Razved. Okhr. Nedr; No. 9, 36-9(Sep 1970). (In Russian).

Three new types of radiometric apparatus are described which are intended for exploration and prospecting for radioactive ores. "Zond-1" may be employed for gamma logging at depths to 1,000 m and a diameter of 36 mm and larger. "Radon" uses a field scintillation emanometer and measures the concentration of radon and thorium in samples of surface air and water samples. The portable scintillation radiometer "SRP-68" is designed for measurements on the surfaces of shot holes and fine crevices. (tr-INIS)

57868 RADIO-ISOTOPE INSTRUMENTATION. Taylor, Denis (Univ. of Strathclyde, Glasgow). IEE (Inst. Elec. Eng.) Rev.; 118: No. 9R, 1090-1106(Sep 1971).

The use, design and performance of the various forms of radioisotope instrumentation are reviewed, with some comment on the historical development of the subject, and possible developments, in the future. Radio-isotope instrumentation comprises a radioisotope source and some measuring component, as used for investigational work in science and engineering, but more particularly in industry to improve both productivity and the quality of the product being manufactured. Emphasis is given throughout to the special techniques involved, and attention is also given, where possible, to applications in electrical engineering. An attempt is made to classify the various applications discussed and to give examples of each class. (auth)

57869 INVESTIGATING THE VIBROCOMPACTING OF CONCRETE MIXES WITH THE USE OF RADIOISOTOPES. Lishanskii, B. A.; Osmachkin, B. P.; Mikhailov, N. V. Beton Zhelezobeton; 16: No. 12, 16-17(1970). (In Russian).

A method was developed for investigating the kinetics of compaction of concrete mixtures and their density changes during vibrocompaction. The vibrocompaction process may be considered complete as judged by the stabilization of movement of a labelled grain in a concrete casting. Block diagrams of the radioisotope-measuring equipment are furnished and discussed. (K.S.W.)

57870 METHOD FOR DETERMINING THE MASS OF DUST DEPOSITED ON MEMBRANE FILTERS BY MEASUREMENTS OF THE ABSORPTION OF BETA RAYS. Liniecki, Julian; Wiecek, Edward; Domanski, Tomislaw. Med. Pracy; 21: No. 6, 608-14(1970). (In Polish).

A simple method was developed for determination of the mass of dust deposited on membrane filters by means of measurements of the absorption of ^{14}C beta-rays (E_{max} = 155 keV). The precision of the method (per cent standard error) is ±9.2% and sensitivity can be expressed as 0.12 mg per cm^2 of the membrane filter. Other filters of similar thickness and filtering ability may also be used. Practical usefulness of the method is emphasized. (auth)

57871 DEVICE AND METHOD USING GAMMA RAYS FOR SIZE AND DENSITY PRODUCE SELECTION. Garrett, Roger E.; Talley, Wilson K. (to Univ. of California). U. S. Patent 3,594,579. 20 Jul 1971. Filed 6 Jun 1968.

A radiometric produce selector for harvesting produce moves a radiation source (viz. gamma rays) relative to the produce with a collimated pencil of radiation traveling through the produce to a receiver on the other side of the produce. The response of the receiver is a direct signal. This may be integrated to provide an indirect signal. These signals are used individually or together to afford a final response. A response exceeding a threshold value can be used to actuate a harvester. The method of selecting produce involves sending a signal through the produce, the signal being attenuated in accordance with the density and size (viz. thickness), and determining the value of the attenuated signal. The system is designed for head lettuce and similar produce. (auth)

57872 APPARATUS FOR DETERMINING THE DENSITY OF PULVERALENT MATERIALS IN RESERVOIR BY MEANS OF A RADIOACTIVE SOURCE AND DETECTOR. Figuet, Maurice G.; Rottner, Gerard; Michaud, Andre Louis (to Fabriques de Produits Chimiques de Thann et de Mulhouse). U. S. Patent 3,582,647. 1 Jun 1971. Filed 27 Aug 1969.

An apparatus and process is described for checking the flow of pulverulent materials contained in a reservoir, which consists of measuring the absorption of an electromagnetic radiation of suitable frequency by the mass of material situated in the reservoir at the level of measurement. (auth)

57873 IONIZATION FIRE DETECTION DEVICE. Ponsar, Christian Marie Maurice Bertrand (to Vigifeu). U. S. Patent 3,582,646. 1 Jun 1971. Priority date 6 Feb 1967, France.

A fire detection device comprising an enclosure enclosing a reference ionization chamber and an unsaturated measuring ionization chamber interconnected in series and each containing a source of radioactive radiations, at least one alarm and/or automatic intervention device, a grid permeable to gases defining one end of the enclosure, the enclosure having apertures communicating with passages at one end of the unsaturated chamber so that gas can flow through the unsaturated chamber, from outside the device, a common electrode extending into both chambers and a printed circuit controlling the alarm and/or intervention device is described. (auth)

57874 CHOICE OF SOURCE ENERGY AND ACTIVITY FOR A RADIOMETRIC METHOD OF ISOTOPE NONDESTRUCTIVE TESTING. Pokrovskii, A. V.; Ripp, A. G. (Tomsk Polytechnic Inst., USSR). Defektoskopiya; No. 2, 108-11(1971). (In Russian).

Current methods of selecting gamma-radiation sources for defectoscopy were examined, and some of their deficiencies were demonstrated. It was shown that the choice of the source energy is directly determined by its activity. Some quantitative results are presented in connection with the selection of source energy and activity for control of steel products of various thickness by means of a radiometric method. (tr-auth)

Miscellaneous Instruments and Components

57875 (INR-1319) INTERCOMPARISON MEASUREMENTS OF THE SKODA AND INR CALORIMETERS ON THE EWA-10 REACTOR. Kott, J.; Jirousek, V.; Teren, S.; Labrousse, M.; Ondricka, K.; Stefanik, J.; Labno, Leszek; Janikowski, Andrzej;

Lopuszynski, Jerzy; Byszewski, Witold; Kot, Janusz (Institute of Nuclear Research, Warsaw (Poland)). 1971. 19p. Dep. NTIS (U. S. Sales Only).

The aim of this experiment was to compare the properties of the SKODA-type calorimeters and the calorimeter constructed in the Neutron Detectors Laboratory of Reactor Physics Department of the INR specially for application in low-intensity reactor radiation fields. The measurements were performed on the EWA-10 reactor at Swierk. A good agreement between the measurement results was obtained using both types of calorimeters, and their applicability for measurements in zero-power reactors was confirmed. (auth)

57876 NEW HIGH-STABILITY NICKEL ALLOY THERMOCOUPLE. Northover, E. W.; Hitchcock, J. A. (Central Electricity Research Labs., Leatherhead, Eng.). Instrum. Pract.; 25: No. 9, 529-31(Sep 1971).

A thermocouple is proposed comprising a positive limb of 87:13 nickel-chromium alloy and a negative limb of 97:3 nickel-silicon alloy which will have a stability comparable with the noble thermocouples (such as Pt. Rh/Pt.) combined with the high sensitivity of the conventional Ni.Cr/Ni.Al thermocouples. Its temperature limit is expected to be similar to that of Ni.Cr/Ni.Al, i.e. ~ 1200°C and it should be suitable for use in reactor environments (cf. Pt.Rh/Pt.). An e.m.f./temperature calibration for the new thermocouple is given. (auth)

57877 CHARACTERIZATION OF A DIFFUSION TUBE HYDROGEN DETECTOR IN A DYNAMIC SODIUM SYSTEM. Roy, Prodyot; Rodgers, Douglas N. (General Electric Co., Sunnyvale, Calif.). Nucl. Technol.; 12: No. 4, 388-92(Dec 1971).

Monitoring of hydrogen in liquid sodium with a diffusion tube type hydrogen detector has recently become of interest in the liquid metal fast breeder reactor (LMFBR) development program. The present investigation was undertaken to characterize a diffusion type detector and to study sodium-hydrogen chemistry with the aid of the detector and gas chromatography. The study was carried out in a cold trapped, pumped sodium loop. It was observed that the activity of hydrogen in sodium and in the cover gas is controlled by the temperature of the cold trap. This study also showed that at lower concentrations of hydrogen (~<2 ppM), the activity of hydrogen in sodium decreases with increasing temperature, which is believed to be due to the interaction between oxygen and hydrogen. However, at higher hydrogen concentrations (~>2 ppM), the activity of hydrogen is independent of temperature. Finally, it was observed that the permeation of hydrogen dissolved in sodium through a stainless steel membrane is a diffusion controlled process. (auth)

57878 POSSIBILITY OF VARIATIONS IN UNIT PULSES OF RADIATIVE HEAT. Ogorodnik, S. S.; Tsoglin, Yu. L. This paper was summarized in At. Energ. (USSR); 29: No. 5, 362-3(Nov 1970) as paper No. 438/5634. (In Russian).

Full copy of this paper is held by DTIE.

The design and operation of a thermodiverger for measuring pulsed quantities of heat are described. Calibration data for a thermodiverger for measuring the heat generated by radiation in the structural materials of a nuclear reactor operating with unit pulses 50 sec long are presented. (W.H.K.)

57879 INVESTIGATION OF THE CALIBRATION CHARACTERISTICS OF A RADIATION THERMODIVERTER IN HIGH-INTENSITY FIELDS OF IONIZING RADIATIONS. Karasev, V. S.; Ogorodnik, S. S.; Tsoglin, Yu. I. This paper was summarized in At. Energ. (USSR); 29: No. 6, 449(Dec 1970) as paper No. 447/5834. (In Russian).

Full copy of this paper is held by DTIE.

An integrated heat flux calorimeter, known as a radiation thermodiverter (RTD), is proposed for measuring heat generated by radiation. This device features high accuracy, high sensitivity, quick response, and arbitrary shape and size. The behavior of the calibration curves of the RTD in response to irradiation was studied experimentally and the results of long-term radiation stability tests directly in the core of the nuclear reactor are reported. (W.H.K.)

57880 CAMAC DATAWAY AND BRANCH HIGHWAY SIGNAL STANDARDS. Larsen, R. S. (Stanford Univ., Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 26-32(Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The basic dataway operation is briefly described to illustrate the use of various control lines. Voltage, current, and timing characteristics of CAMAC Dataway and Branch Highway signals are given. (R.W.R.)

57881 SHORT DESCRIPTION OF THE CAMAC BRANCH HIGHWAY. Kirsten, Frederick A. (Univ. of California, Berkeley). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 19-25(Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A short summary and description of the CAMAC Branch Highway are presented. The purpose of the Branch and some of its characteristics are explained. Certain operational sequences are described in detail. (auth)

57882 OPERATIONAL CHARACTERISTICS OF THE CAMAC DATAWAY. Kirsten, Frederick A. (Univ. of California, Berkeley). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 9-18(Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The basic purpose of CAMAC is to provide a standardized method for transmitting data and control information between instrumentation modules and a digital controller. CAMAC encompasses both a hardware standard for housing the modular components of a system and an electrical and logical standard for the control "language" used in the transfer of digital information. The CAMAC specification contains the rules for both of these aspects of CAMAC. The features and uses of the control language are described in a less formal way than that used in the specification. Examples are given of the interplay of control and synchronization signals between the modules concerned. This paper is designed to supplement the CAMAC specification. (R.W.R.)

57883 CAMAC INSTRUMENTATION SYSTEM: INTRODUCTION AND GENERAL DESCRIPTION. Costrell, Louis (National Bureau of Standards, Washington, D. C.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 3-8(Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The CAMAC instrumentation system, developed by the ESONE Committee of European laboratories, has been endorsed by the U. S. AEC NIM Committee as a dataway system complementary to the NIM (Nuclear Instrument Module) system. CAMAC is described in a general way. (auth)

57884 COMPUTER CONTROLLED CAMAC SYSTEMS AT ARGONNE. Strauss, M. G.; Lenkszus, F. R.; Brenner, R.; (and others) (Argonne National Lab., Ill.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 46-52(Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Several computer-controlled CAMAC systems are presently being developed at Argonne for data acquisition in low-energy nuclear physics. Four of these are discussed. The systems are designed around 8K, 16-bit, Lockheed MAC-16 computers. A typical system includes two CAMAC crates and a complement of 15 modules. The crate controller in each crate serves as interface between the computer I/O bus and the CAMAC dataway. Up to 14 individual crates can be addressed in addition to a Teletype and other peripheral devices. The CAMAC modules being developed include Crate Controller, Dual ADC Controller, ADC Coincidence Unit, Dual Stabilizer, Quad Pre-Scaler, Clock, Display Controller, Readout Selector, Magnetic Tape Controller, and Disk Controller. Most units are built in double-width modules using computer-controlled wire-wrap construction. (auth)

57885 SOME CHARACTERISTICS OF INTERFACES BETWEEN CAMAC AND SMALL COMPUTERS. Kirsten, Frederick A. (Univ. of California, Berkeley). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 39-45 (Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The typical CAMAC system has a small computer attached to it. In the usual case, the computer acts as a repository for data generated by CAMAC, and also controls and directs the CAMAC operations. Some of the aspects of the hardware interface, as well as some of the interaction between the computer and the CAMAC system, are discussed. (auth)

57886 PROPOSAL OF A UNIQUE NOMENCLATURE FOR VOLTAGE COMPARING ADC's. Drosg, M. (Los Alamos Scientific Lab., N. Mex.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 117(Apr 1971).

A simple scheme is given from which names for the five basic voltage-comparing ADC's can be obtained uniquely. (auth)

57887 USE OF AN ON-LINE DIGITAL COMPUTER FOR ENHANCEMENT AND INTEGRATION OF NUCLEAR RESONANCE

XUM

SPECTRA. Waymark, R. D. B.; Bowman, D. R. (University Coll., London). Radio Electron. Eng.; 41: No. 8, 421-9(Sep 1971).

The design and practical considerations involved in coupling a small digital computer to work on-line with a chemical research n.m.r. spectrometer are described. The various requirements of spectrometer, computer, interfacing and programming are dealt with both in general terms and in relation to the specific system employed in the described project. The effectiveness of the practical system is assessed, and some typical results are included. (auth)

57888 SUMMARY OF CAMAC: STATUS AND OUTLOOK. Mack, Dick A. (Univ. of California, Berkeley). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 69-70 (Apr 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The status of CAMAC is reported, along with its relation to the NIM system. Up-to-date specifications for CAMAC power supplies are given. (R.W.R.)

57889 TWO-CHANNEL DEFECTOSCOPE. Nedavnii, O. I. (to Nautchno Issledovatelskii Institut. Tomskom Politekhnitcheskom Institut). Russian Patent 270,320. 8 May 1970. Filed 14 Jun 1965. (In Russian).

A defectoscope with two channels and a radiation source is described. Diagrams of this device are also included. (J.F.P.)

57890 60^0 SECTOR MASS SPECTROMETER FOR GAS ANALYSIS. Prahallada Rao, B. S.; Murthy, M. S.; Rama Rao, V. V. K. (Bhabha Atomic Research Centre, Bombay). Indian J. Technol.; 9: No. 2, 47-50(Feb 1971).

A mass spectrometer of 10 cm radius and 60° magnetic sector field has been designed for gas analysis work. A new, bakeable, all-stainless steel valve is used in the sample handling system. A resolution of around 80 and a sensitivity of 10^{-10} torr for the partial pressure of nitrogen were obtained. The degree of resolution obtained with the instrument is adequate for routine analysis of gases and gas mixtures. (auth)

57891 CALCULATION, CONSTRUCTION, AND TESTING OF COLLIMATORS USED FOR SCINTIGRAPHY WITH LOW-ENERGY RADIONUCLIDES. Zeidler, U.; Geisler, S. (Institut fuer Nuklearmedizin und Spezielle Biophysik, Hanover). Nucl.-Med.; 10: No. 2, 167-95(15 Jul 1971). (In German).

A simplified method is described of calculating and constructing collimators for use in scanning with low-energy radionuclides. The construction of three out of eight collimators built using this method is described in detail. These collimators — a 217-hole collimator with medium resolution, a 490-hole long-focus and a 856-hole fine-focus collimator — were tested by means of line-spread functions. The results showed good correlation with the calculations. (auth)

57892 METHOD FOR THE DESIGN OF NEAR-OPTIMUM FILTERS FOR NUCLEAR SIGNAL TRANSMISSION SYSTEMS. Battista, A. J. (Lockheed Palo Alto Research Lab., Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 142-7(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A novel approach for designing near-optimum filters for coaxial transmission lines carrying nuclear signals is presented. The method involves a non-linear least-squares fitting of the filter parameters to best-fit the desired ideal response. Unlike previous empirical methods to match the amplitude response of the cable, the fitting is done to both amplitude and phase responses. The algorithm used in order to determine the best set of filter parameters is one that combines the best features of the gradient search method on the hyper-surface formed by the parameters with the analytical solution of the fitting function; this combination provides fast convergence. After the set of filter parameters that give the best fit to the ideal response is determined, the actual filter is designed. A computer program developed to do the fitting and design and to display the results in both tabular and graphical forms. (auth)

57893 DESIGN AND CONSTRUCTION OF A FOUR-DECADE DIGITAL LOG RATEMETER. Thorington, John M. Jr. (Auburn Univ., Ala.); Andrews, Vernon E. IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 148-54(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A four-decade digital log ratemeter using integrated circuits for all active components was designed and tested. The ratemeter is capable of measuring pulse rates ranging from 1.11×10^{-1} to 2.0×10^7 pulses per second. With a very simple modification the ratemeter can be made to have any desired number of decades in its output. The input pulse rate is determined by digital counting circuits; and the logarithm of the pulse rate is approximated by seven digital functions, which are generated by a series of combinational logic networks. The output is available in either digital or analog form. The system is composed of the following sections: timing and control, counting, transfer, round-off, log converter, storage, and digital-to-analog converter. Experimental results showed that the digital log ratemeter has, for the same statistical accuracy, a much faster response time than conventional log ratemeters. It was shown also that the digital log ratemeter is capable of being used to measure much lower pulse rates than is practicable with conventional log ratemeters. (auth)

57894 MOSFET CURRENT-TO-FREQUENCY CONVERTER WITH A LINEAR SUB PICOAMPERE-TO-MICROAMPERE RANGE. Shapiro, Edward G. (Univ. of California, Livermore). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 155-9(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A current-to-frequency converter with a single linear current range of 10^{-13} to 10^{-6} amperes was developed for monitoring ion chamber currents. The converter has an output transfer function of 10^{-11} amperes/Hz or 10^{-11} coulombs/count that is temperature compensated. Its frequency output, which is compatible with most scalers, yields a maximum linear rate of 10^5 Hz at 10^{-6} amperes input current. (auth)

57895 DELAY TIME STUDIES IN A CHANNEL ELECTRON MULTIPLIER. Briscoe, William L. (Los Alamos Scientific Lab., N. Mex.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 222-3(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Delay time and gain for a Bendix 4028 Channeltron was studied during accelerated life tests. The results are presented along with a suggestion for delay compensation. Novel means for synchronous stimulation of the multiplier and for measurement of the output charge are presented. (auth)

57896 PROGRAMMABLE SOLID STATE PULSER FOR CHARGE-SENSITIVE AMPLIFIER SYSTEMS. Burtis, D. W. (Time-Zero Corp., Torrance, Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 282-6(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A circuit was developed which allows excitation of charge-sensitive amplifiers at high pulse repetition rates. The amplifier output waveform fidelity is nearly as good as that associated with low-repetition-rate mercury-relay pulsers. The circuit may be self-contained or operated under external control by supplying a reference voltage and clock signals to initiate pulses. The elements of the pulser are discussed in detail, and some applications are suggested. The circuit was tested for amplitude stability as a function of temperature and pulse repetition rate. (auth)

57897 COMPUTER CONTROLLED INSTRUMENTATION FOR PLUTONIUM MEASUREMENT. Lawless, J. L.; Anna, T. L. (Dow Chemical Co., Golden, Colo.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 327-31(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A small digital computer was successfully interfaced to nuclear counting systems in a plutonium recovery facility. The counting systems are used to measure plutonium content of waste and process residues. The computer initializes the counting sequence, accepts the data, computes the plutonium content, and prints the documented information. (auth)

57898 NUCLEAR REACTOR APPLICATIONS OF NEW ULTRASONIC TRANSDUCERS. Lynnworth, L. C. (Panametrics, Waltham, Mass.); Papadakis, E. P.; Patch, D. R.; Fowler, K. A.; Shepard, R. L. IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 351-62(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

New high-temperature and broadband magnetostrictive and piezoelectric ultrasonic transducers have been developed for testing, measurement, and control. Potential reactor applications include measuring fuel centerline temperature, sodium temperature profile (ten points with only one wire), occurrence and location of bubbles in liquid coolants, liquid level, flow, gas pressure, nondestructive testing, and acoustic emission surveillance. (auth)

57899 AUTOMATIC-RANGING PICOAMMETER FOR REACTOR CONTROL AND PROTECTION. Ball, R. M.; Lovallo, J. M. (Babcock and Wilcox Co., Lynchburg, Va.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 435-7 (Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

An automatic-ranging picoammeter covering full-scale ranges from 3×10^{-11} to 1×10^{-3} amperes with a 50% over-range capability has been designed, built, tested, and installed for use with Babcock & Wilcox's Lynchburg Pool Reactor. The unit incorporates three major improvements over previous instrumentation and commercially available equipment: elimination of manual range changing, provision for adjustable power level trips throughout the operating range of the reactor, and provision for a trip function upon detection of a period shorter than that preset into the instrument. (auth)

57900 CONTINUOUS CONCENTRATION DEVICE FOR RADIOACTIVE WASTE WATER. (to Licentia Patent-Verwaltungs GmbH). French Patent 2,000,999. 19 Sep 1969. Priority date 30 Jan 1968, Germany. (In French).

An apparatus is described for the continuous concentration of radioactive waste water in a vessel serving likewise for longtime storage in which the waste water is heated without stirring. The heat source is arranged in the interior of the vessel and heats the surface of the water without bringing it to the boiling point. A gas entering through an orifice is used to sweep the evaporated liquid from the vessel, and a heating device, arranged laterally at the bottom of the vessel on the outside, produces a circulation of the concentrate. (E.J.H.)

57901 DOUBLE-FOCUSING QUADRUPOLE LENS SPECTROMETER AND ITS USE IN THE STUDY OF VARIOUS NUCLEAR REACTIONS. Green, Ray E. L. Boulder, Colo.; Univ. of Colorado (1970). 145p. University Microfilms Order No. 71-21,590.

Thesis.

Various methods of using the chromatic aberration inherent in magnetic quadrupole lenses as the basis for constructing low-resolution spectrometers and magnetic rigidity band-pass filters that require the use of only one relatively small detector are studied. The thick-lens approximation for the behavior of quadrupole lenses is used; corrections to this approximation because of imperfections in magnetic lenses are discussed. The various methods of utilizing a quadrupole doublet to construct such a system are discussed extensively, and systems based on a quadrupole triplet are considered briefly. An operational system utilizing a quadrupole doublet is described, and data from representative experiments for which the system has been used are presented to demonstrate the potential that such systems possess. The ^{46}Ti(^{3}He,t)^{46}V reaction for an incident ^{3}He beam energy of 37.7 MeV is discussed in detail. Data taken between scattering angles of 5 and 25 degrees with the double-focusing quadrupole-lens spectrometer developed and other data available between 17.5 and 45 degrees are used with the distorted-wave Born approximation (in which the interaction potential used includes a tensor force term) to determine tentative spin assignments for five states in ^{46}V and to restrict the spin assignments for eleven other states to two or three possibilities. (Diss. Abstr. Int., B)

57902 RECENT ADVANCES IN GAS-DISCHARGE DUPLEXERS. Paik, S. F.; Jellison, F. A. (Microwave Associates Inc., Burlington, Mass.). pp 201-6 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

The use of radioactive primers in microwave gas discharge switches is discussed, as representing an improvement in reliability. The most promising of these are T and ^{63}Ni, the former being used as a metal tritide, such as Ti tritide. The advantages and disadvantages of each are stated. Experiments to test the effectiveness of radioactive primers are indicated. Overall, T is to be preferred. (UK)

57903 CHANGES OF NONLINEAR PARAMETERS OF SEMICONDUCTOR RESISTORS (VARISTORS) OF BLACK SILICON CARBIDE AS A RESULT OF GAMMA IRRADIATION. Kashukeev, N.; Ribarov, S.; Krezhov, K. (Inst. of Physics, Sofia). Compt. Rend. Acad. Bulg. Sci.; 24: No. 4, 435-8(1971). (In Russian).

Black silicon carbide semiconductor resistors (varistors) were exposed to gamma radiation at 10R/sec from a ^{60}Co source and then tested on a modified Wheatstone bridge for resistance changes. The data obtained showed that both static and differential resistances were altered similarly: with increased gamma dose the resistance fell to a minimum, and then increased, the minimum occurring at about 0.8×10^{6} R. Two possible competing processes which may explain this phenomenon are discussed. (K.S.W.)

57904 MODIFICATION OF THE TRAC EBERS–MOLL MODEL FOR IMPROVED HIGH FREQUENCY AND COLLECTOR STORAGE TIME PREDICTIONS. Maldonado, C. D.; Kleiner, C. T. (Autonetics, Anaheim, Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 71-83(Apr 1971). (CONF-700713–2). Fro

From Conference on nuclear and space radiation effects; San Diego, Calif. (21 Jul 1970).

The TRAC Ebers-Moll model is modified in order to obtain an improved high frequency prediction. This is achieved by means of a three lump Linvill model to account for diffusion transport of minority carriers in the base region of a bipolar transistor. The modified Ebers-Moll model obtained in this manner yields two pole representations for the transport factors in the frequency domain. The two pole representation for h_{fe} is shown to give reasonable fit both in amplitude and phase with experimental data obtained from a low frequency bipolar transistor, while the phase correlation obtained with the single pole representation of the present TRAC Ebers-Moll model is unsatisfactory, especially at high frequencies. The present TRAC Ebers-Moll model was also modified so as to obtain an improvement in collector storage and recovery time prediction. This was accomplished by the introduction of two Linvill lumps in the collector region to account for minority carrier storage and transport. The observed experimental collector-base diode turn-off transient response for the same low frequency bipolar transistor was found to be in agreement with the prediction of the modified model. Also, a discussion of a modified model to account for both the high frequency response, as well as collector storage and recovery time effects is presented. (auth)

57905 IMPROVED FAST NEUTRON TOLERANCE OF GaAs JFET's OPERATING IN THE HOT ELECTRON RANGE. McNichols, J. L.; Zuleeg, R. (McDonnell Douglas Astronautics Co., Santa Monica, Calif.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 111-13(Apr 1971).

The fast-neutron-induced degradation of the electrical characteristics of n-channel GaAs junction field-effect transistors (JFET's) operating in the Shockley mode (thermal equilibrium) has been estimated previously. Advances in technology have led to the fabrication of devices and micron-sized channel lengths, which are capable of response at microwave frequencies. Short channel lengths, however, result in device operation under thermal nonequilibrium conditions, and hot electron effects must be considered. The theory of Lehovec and Zuleeg [Solid-State Electron., 13: 1415(1970)], which provides the characteristics for JFET's operating in the hot electron range, is employed to estimate the neutron degradation of these devices. It is shown that JFET's operating in the hot electron range are more resistant to neutron exposure than are JFET's operating in the Shockley region. Devices with channel-doping concentration of 10^{17} cm^{-3} are predicted to survive fluences of 10^{16} neutrons/cm^{2}. Some preliminary test results are reported. (auth)

57906 PERMANENT RADIATION EFFECTS IN SWEPT AND UNSWEPT OPTICAL GRADE SYNTHETIC QUARTZ AT RESONATORS. EerNisse, E. P. (Sandia Labs., Albuquerque, N. Mex.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 2, 86-90(Apr 1970).

Permanent changes in the frequency versus temperature characteristics of unswept and swept optical-grade synthetic-quartz AT resonators that are caused by fast-neutron and ^{60}Co irradiations were investigated. Neutron damage shifts the frequency versus temperature characteristics of the unswept resonators upwards in frequency across the entire zero to +120°C temperature range at a rate of 0.56×10^{-15} ppM per N/cm^{2}, which is the smallest value yet reported in the literature. The observed erratic results for swept resonators were attributed to effects of ionizing radiation accompanying the neutron fluence and led to the ^{60}Co investigation. The unswept optical-grade quartz was found to provide AT resonators that are more resistant to ionizing radiation than any other unswept material yet investigated in the literature. Appreciable amounts of acoustically active defects attributed to Na impurities, which were apparently added during sweeping, were indicated by the ^{60}Co results for the swept devices and made the swept devices useless as radiation-resistant resonators. 57907 ELECTRON RADIATION DAMAGE EFFECTS IN SILICON SURFACE-BARRIER DETECTORS. Liu, Y. M.; Coleman, J. A. (National Bureau of Standards, Washington, D. C.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 192-9(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Silicon surface-barrier detectors were irradiated at room temperature with monoenergetic electrons in the energy range of 200 keV to 1 MeV. The changes of detector reverse leakage current, noise, capacitance, and alpha-particle counting response were determined. In general, detector current and noise increased with electron fluence and energy for electron energies of 400 keV and above. Detector capacitances tended to decrease slightly for electron fluences up to 10^{13} cm^{-2} and increase at higher fluences. No significant degradation of detector performance was observed as a result of irradiation with 200-keV electrons for fluences up to 10^{16} cm^{-2}. The effects of damage on detector performance were reduced when the rear, aluminum contact was irradiated rather than the front, gold contact. (auth)

57908 RADIATION HARDNESS OF A NEW MAGNETIC THIN-FILM RECORDING SYSTEM. Hsieh, E. J.; Winslow, J. W. (Univ. of California, Livermore). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 224-7(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Magnetic thin-film memory units of a new transient-recording system designed for nuclear data acquisition were tested for radiation hardness. The films were exposed to neutron and gamma doses on the order of 10^{12} n/cm^2 and 10^4 R, respectively. Analog signals stored in the films were photographed using a Suchow powder technique before and after the exposure. (auth)

57909 RADIOIMMUNOASSAY FOR CANINE GROWTH HORMONE. Tsushima, Toshio; Irie, Minoru; Sakuma, Maki (Tokyo Univ.). Endocrinology; 89: No. 3, 685-93(Sep 1971).

A sensitive radioimmunoassay capable of detecting concentrations of growth hormone as low as 1 ng/ml of dog plasma was developed using the double antibody method. Antiserum to canine growth hormone (CGH) was prepared in guinea pigs, and it was found to be cross-reactive with porcine, rat, ovine or bovine growth hormone. The radioimmunoassay was applied to the determination of plasma GH levels on unanesthetized dogs under a variety of situations. Mean plasma GH levels after an overnight fast were 3.2 ± 0.5 in normal adult males and 4.3 ± 1.1 ng/ml in normal females. The values in newborn puppies were higher than in the adult dogs. Plasma GH levels in lactating or pregnant dogs were in the range for normal females. Suckling did not cause any detectable change of plasma GH in the lactating dogs on postpartum day 21–24. Exercise of 10 min running was also ineffective. Insulin hypoglycemia as well as a rapid fall of plasma glucose without hypoglycemia produced an increase of plasma CGH. The response to hypoglycemia was, however, quite sluggish in spite of a profound hypoglycemia. An infusion of arginine caused a prompt and marked rise of plasma CGH. Thus, it was found that the dog shares, at least in part, similar secretion patterns of GH with man, sheep and pig, though some differences exist from species to species. (auth)

57910 IVth CONFERENCE OF ELECTRON MICROSCOPY, LUBLIN, NOVEMBER 26–28, 1969. Acta Med. Pol.; 12: No. 2, 1-304(1971). (CONF-691138).

Separate abstracts were prepared on two papers. Twelve additional papers discuss the development and applications of electron microscopy. (C.H.)

For abstracts of individual papers see: 58112 and 58113.

57911 CONDITIONS AND PERSPECTIVES OF THE USE OF ISOTOPES AND RADIATION TECHNIQUES IN HORTICULTURE OF FOREIGN COUNTRIES AND OF HUNGARY. Simon, J.; Zsoldos, L. Izotoptechnika; 14: No. 3, 25-33(Mar 1971). (In Hungarian).

Achievements in the field of radiomutation improvement of plants, radiostimulation and conservation of horticultural products, and the use of tracer method are discussed. Research topics and results in Hungarian institutes are included. (auth)

57912 APPLICATION OF AN INDIRECT PAIRED RADIOIODINE-LABELED ANTIBODY TECHNIQUE TO ADENOVIRUS-12 TUMOR SEROLOGY. McCammon, James R.; Yohn, David S. (Ohio State Univ., Columbus). J. Nat. Cancer Inst.; 47: No. 2, 447-54(Aug 1971).

The indirect paired radioiodine-labeled antibody technique was developed to detect antibodies to adenovirus-12-induced tumor antigen(s). This technique was more sensitive than indirect immunofluorescence and markedly more sensitive than complement fixation. It provides a means to rapidly screen large numbers of sera for antibodies to various virus-induced antigens. (auth)

57913 USE OF RADIONUCLIDES IN FOOD SCIENCE AND TECHNOLOGY. Fischer, Erich (Bundesforschungsanstalt fuer Lebensmittelfrischhaltung, Karlsruhe, Ger.). Lebensm.-Wiss. Technol.; 2: No. 1, 1-8(1969). (In German).

A survey was made on radionuclide application in food research and technology. Topics discussed include: the use of radioisotope labeling for the study of milk and milk products; meat; grains, flours, and baking; brewing; packaging materials; and treatment of foodstuff with chemicals. In addition, from the standpoint of the food industry, the survey includes radiometric procedures, natural radioactivity of foodstuff, and neutron activation analysis. 121 references are given. (H.B.G.)

57914 USE OF A DOUBLE-ISOTOPE DERIVATIVE PLASMA ASSAY FOR NORADRENALINE AND ADRENALINE IN THE DIAGNOSIS AND LOCALISATION OF PHAEOCHROMOCYTOMA. Louis, W. J.; Doyle, A. E. (Univ. of Melbourne). Aust. N. Z. J. Med.; 1: No. 3, 212-17(Aug 1971).

A sensitive double-isotope radioimmunoassay method was developed to measure total plasma catecholamines, noradrenaline (NA) and adrenaline (A) in patients with phaeochromocytoma and essential hypertension. Plasma samples containing as little as 0.5 ng of NA or A could be measured accurately. All nine patients with phaeochromocytoma had significant elevations in either total plasma catecholamines or plasma NA. Separation of NA and A with less than 0.3% cross contamination was carried out by thin layer chromatography. This represents a substantial improvement over other methods of assay and raises the possibility that differential plasma assay of NA and A will be of value in diagnosing extraadrenal tumors. Differential plasma NA and A levels were measured in five patients with phaeochromocytoma. Four of these had elevated NA and A levels and were later found to have adrenal tumors. The other patient had a mediastinal tumor and no measurable plasma adrenaline. (auth)

Metabolism, Physiology, and Toxicology

57915 USE OF RADIOACTIVE IODINE IN DETERMINING THE FUNCTIONAL ACTIVITY OF THE THYROID GLAND OF GERBILS. Akhmetov, I. Z. (Inst. of Zoology and Parasitology, Tashkent). Uzb. Biol. Zh.; No. 2, 61-2(1971). (In Russian).

Iodine-131 was used as a radioindicator of the functional state of the thyroid gland of half-grown gerbils weighing 180 to 200 g. (Rhombomys opimus Lichtenstein). The course of the ^{131}I was followed from the moment of injection of 0.4 to 0.5 mCi under the skin of the rear paw. About 18% appeared in the urine during the first 24 hr; an insignificant fraction appeared in the feces. Between 16 and 20 hr after injection the iodine could no longer be counted. The maximum level of ^{131}I was reached between 8 and 24 hr (28.4 to 26.2% of the initial quantity). (K.S.W.)

57916 COMPARATIVE TOXICITY OF TRITIUM OXIDE FOR VARIOUS TYPES OF ANIMALS. Zhuravlev, V. F. Gig. Sanit.; No. 6, 49-51(Jun 1971). (In Russian).

Data on different sensitivities of animals to the action of tritium oxide are presented. In the study of comparative toxicity various indices were analyzed. The dogs were found to be most sensitive to tritium oxide. The sensitivity of an animal to the action of this isotope depended greatly on the extent of affection of the hemopoiesis and the rate of restoration processes in various types of animals. (auth)

57917 COMPARATIVE BEHAVIOR OF ^{89}Sr AND ^{140}Ba IN THE SKIN AFTER THEIR CUTANEOUS APPLICATION. Shvydko, N. S.; Il'in, L. A.; Norets, T. A.; Antonova, V. A. Gig. Sanit.; No. 6, 45-8(Jun 1971). (In Russian).

Quantitative data are presented on the distribution of isotopes in lipid soluble, water soluble, and residual fractions of the epidermis, dermis, and subcutaneous tissue after application of the isotopes to the skin for 15 and 24 hrs. A comparative analysis of the distribution of ^{89}Sr and ^{140}Ba in the skin was made, and possible mechanisms of fixation of these isotopes in structures of the skin are discussed. (auth)

57918 GROWTH DYNAMICS OF OSTEOSARCOMAS IN BEAGLES. Thurman, Gary Boyd. Salt Lake City; Univ. of Utah (1971). 141p. University Microfilms Order No. 71-20,140.

Thesis.

Two hundred and fifty-six well-documented osteosarcomas have been induced in 201 beagles, each receiving a single intravenous injection of ^{226}Ra (80 tumors), ^{239}Pu (64 tumors), ^{228}Ra (43 tumors), ^{228}Th (56 tumors), ^{90}Sr (8 tumors) or ^{224}Ra (5 tumors). Radiographs of each osteosarcoma were taken during the period of the tumor's growth. The growth dynamics of these osteosarcoma were estimated by measuring the tumor dimensions on as many radiographs as possible. It was clearly evident that the tumor volumes were increasing exponentially with time. Exponential growth constants were calculated for 249 tumors, the corresponding volume doubling times ranged from 4.7 to 60.3 days and averaged 12.4 days. Using individual exponential growth constants, a starting time for each tumor was estimated as the time when the extrapolated tumor's growth curve reached the volume of one cell 10 μ ($\mu = 10^{-4}$ cm) in diameter. The accumulated average skeletal dose during the time from injection to tumor starting time was calculated for each tumor and called the oncogenic skeletal dose. It was found that the larger the amount of radionuclide injected, the larger the oncogenic skeletal dose. High incidences of radiation-induced osteosarcomas in the beagles were noted in vertebrae, pelvic bones, humerii, femora, and tibiae. Radiation-induced osteosarcomas of the vertebrae and pelvic bones had much higher incidences than the corresponding incidences of naturally-occuring osteosarcomas in dogs. (Diss. Abstr.)

57919 ASSESSMENT OF INTERNAL CONTAMINATION RESULTING FROM RECURRENT ON PROLONGED UPTAKES. Recommendations of the International Commission on Radiological Protection. A Report of ICRE Committee 4. ICRP Publication 10A. Oxford; Pergamon Press (1971). 39p. £ 1.25.

Mathematical formulas are presented for use in calculations of the retention and excretion times of a selected list of radioisotopes in man. Factors considered include: declining uptake over an indefinite period following a single exposure (retention of non-transportable radionuclides in the lungs, deposition in pulmonary lymph nodes from contaminated lungs, urinary excretion from contaminated lungs, deposition in the skeleton from contaminated lungs, deposition in the skeleton and excretion after contamination of wounds); and several uptakes during a limited time period (differences between the metabolism of bone-seeking radionuclides and others). Appendices cover: derivation of basic equations, retention and excretion functions for ten radionuclides (^{3}H, ^{90}Sr, ^{132}Te, ^{132}I, ^{131}I, ^{137}Cs, ^{226}Ra, ^{233}U, ^{234}U, ^{239}Pu); the fractions of the total excretion by urine (F_u) and feces (F_f) for elements taken up by extracellular fluid; and data on excretion following periods of constant uptake. (UK)

57920 ENHANCEMENT OF THE CARCINOGENICITY OF 7,12-DIMETHYLBENZ[a]ANTHRACENE THROUGH REPLACEMENT OF HYDROGEN BY DEUTERIUM: A NEW BIOLOGICAL ISOTOPE EFFECT. Buu-Hoi, N. P.; Nguyen, Ba Giao (Centre National de la Recherche Scientifique, Paris). Naturwissenschaften; 58: No. 7, 371(Jul 1971).

Evidence is given to show that 7, 12-dimethylbenz[a]anthracene-d_{16} (I) is, effectively, a significantly more potent carcinogen than ordinary 7, 12-dimethylbenz[a]anthracene (II). The deuterated compound, dissolved in neutral olive oil, was administered subcutaneously to 57 three-month old mice. Each animal received a total dose of 1.5 mg of (I) in three injections at 1-month intervals. Controls were treated with the non-deuterated compound (II). The experiment lasted for 395 days. The tumors observed were fibroblastic sarcomas, either simple or, in a few cases, associated with a baso-cellular or an epidermoid epithelioma. It was concluded that compound (I) is an extremely potent local carcinogen, whose sarcomagenic activity significantly surpasses that of its non-deuterated equivalent (II). (P.C.H.)

57921 CELL LINE INITIATION FROM CORD BLOOD LEUKOCYTES TREATED WITH VIRUSES, CHEMICALS, AND RADIATION. Chang, R. Shihman; Hsieh, Mei-whey; Blankenship, Willard (Univ. of California, Davis. Sacramento Medical Center, Calif.). J. Nat. Cancer Inst.; 47: No. 2, 479-83(Aug 1971).

The initiation of cell lines from leukocytes from human umbilical cord blood treated by the Kaplan cell filtrate, simian virus 40 (SV40), x irradiation, and five chemical carcinogens was attempted. From 45 control and 41 Kaplan cell filtrate-treated cultures, 0 and 19 lines were initiated, respectively. In contrast, SV40, x irradiation, and the five chemical carcinogens used were ineffective in initiating cell lines. (auth)

57922 FATE OF ^{252}Cf IN THE RAT. Mewhinney, James Albert. Lafayette, Ind.; Purdue Univ. (1971). 129p. University Microfilms Order No. 71-20,506.
Thesis.

The retention, excretion and distribution of ^{252}Cf citrate injected into the intraperitoneal cavity of male rats weighing 120 to 140 grams were studied for periods up to 64 days after injection. All quantification of ^{252}Cf was accomplished with an external sample liquid scintillation counting system calibrated to detect the emissions from the spontaneous fission decay of the radionuclide. Whole body retention of ^{252}Cf was determined on a group of 5 rats over the 64 day period. A three component exponential equation was fitted to the mean daily retention data using a nonlinear weighted regression analysis program. The fitted equation $BB(t) = 22.85e^{-3.05t} + 15.69e^{-0.081t} + 61.46e^{-0.00065t}$ had a computed correlation coefficient of $(r) = 0.996$ indicating the equation was an adequate description of the data. The calculated effective partial half-lives corresponding to these three components were 2.2 hours, 8.5 days since 1072 days. The long term component is longer than the physical half-life of 966 days, an impossibility The lower limit of the nonlinear 95% confidence interval about this long term component gives a calculated effective partial half-life of 700 days. Thus, the true effective partial half-life is probably between 700 and 966 days. The daily excretion of ^{252}Cf was greatest in the urine for the first 24 hours after injection when 20% of the initial body burden was eliminated. Thereafter fecal excretion was predominant throughout the 64 day experiment period. The total accumulative excretion data closely supported the whole body retention data obtained by whole body counting. The organ and tissue distribution of ^{252}Cf was determined in a serial sacrifice experiment. Groups of six rats were injected and maintained for periods of 1, 2, 4, 8, 16, 32 and 64 days. Initial deposition of ^{252}Cf was greatest in the skeleton with 60.4% of the initial body burden being retained at one day. The skeleton retained this deposition tenaciously, only about 8% of the initial activity was lost in 64 days. The liver, gastrointestinal tract, kidney, and soft tissues initially deposited 7.48, 2.26, 1.98 and 2.00% of the initial body burden. The content of ^{252}Cf in these organs and tissue had declined to less than 1% of the initial body burden by 32 days after injection. The localization of ^{252}Cf in the femur was studied using alpha autoradiography. Sections of undecalcified bone were exposed on 50 micron-thick NTA emulsion slides and developed in the normal manner. Alpha track counting techniques were used to assess the relative radiation dose to the endosteal periosteal and Haversian system of bone surfaces. Assuming that the radiation dose to the above surfaces directly related to the number of alpha particles detected, the periosteal surface received nearly twice the radiation dose as the endosteal surface due to initially deposited ^{252}Cf. However, remodeling grossly changed this pattern of dose distribution in both time and space. Apposition and resorption on bone surfaces caused the relative radiation dose to bone surfaces to vary by factors as large as 25 to 50. (Diss. Abstr.)

57923 PULMONARY CELL RESPONSES TO METALLIC OXIDES. Casarett, Louis J.; Casarett, Margaret G.; Whalen, Stephanie A. (Univ. of Hawaii, Honolulu). Arch. Intern. Med.; 127: 1090-8(Jun 1971).

When the phagocytic response of pulmonary cells obtained from rat lung lavage to insoluble particles was assessed in an in vitro system under conditions of selected variables, a peak phagocytic response occurred for most metal oxides (except Fe_2O_3) at 10^{-4} M Ca^{2+} and at 10^{-7} M UO_2^{2+} in a simple saline medium. The Ca^{2+} effect was interrelated with particle concentration for SiO_2 particles. Phagocytic response increased with particle to cell ratios up to 10 to 15 with several particle species. These and other data including enhanced phagocytosis with poly-L-lysine, are discussed in relation to peritoneal cell responses, charge characteristics of particles, and the implications of the findings to in vivo lung responses. (auth)

57924 FLUID AND ELECTROLYTE SPACES IN CHRONIC RENAL INSUFFICIENCY. Vorburger, Chr. (Staedtisches Krankenhaus, Baden, Ger.). Helv. Med. Acta, Suppl.; No. 51, 1-142(1971). (In German).

Discussed is the isotope dilution principle and the physiological behavior of tritium-labeled water, ^{24}Na, ^{42}K, and ^{82}Br. By means of these isotopes, simultaneous determination was performed for exchangeable body sodium, exchangeable body potassium, the ^{82}Br distribution space, total-body water content, and plasma volume. The study included investigations on all patients in the chronic hemodialysis station of the medical outpatient clinic at the university of Bern and 44 conservatively treated chronic uremic patients; in all, 83 isotope studies were done. Results showed a significant correlation between blood pressure and all of the extracellular fluid spaces. While in 90% of the patients high blood pressure disappeared with correction of the excess fluid, 10% retained hypertension. All of the patients who showed a pathological glucose tolerance also showed a reduction in intracellular potassium. (H.B.G.)

57925 EFFECTS OF ULTRAVIOLET IRRADIATION ON DNA SYNTHESIS IN CHLAMYDOMONAS REINHARDI. White, Michael Thomas. Los Angeles; Univ. of California (1971). 148p. University Microfilms Order No. 71-21,343.
Thesis.

The dark repair of DNA following UV irradiation was investigated in the wild type of the unicellular green alga Chlamydomonas reinhardi. Experiments with radioactive nucleic acid precursors suggested that pyrimidines are not incorporated into DNA to any appreciable extent in this organism. This precluded quantitative experiments that would demonstrate excision of pyrimidine dimers as a model of DNA repair. In the dark cells with ^{3}H-thymidine prelabeled DNA responded to UV irradiation by releasing ^{3}H into the growth medium and a decreasing specific activity of ^{3}H in DNA. Since pyrimidine dimers could not be demonstrated, the release of label was only suggestive of excision repair. Repair replication was investigated by density transfer experiments and observation of unscheduled DNA synthesis. Synchronized cultures incorporated ^{32}P label into DNA in the dark following UV irradiation. Control cultures incorporated little label for up to 4 hours of dark incubation. Apparently, UV irradiation stimulates DNA synthesis in the dark under conditions where DNA synthesis would not normally occur. Density transfer experiments were performed using ^{15}N as a heavy density DNA label. Attempts to characterize repair replication as single stranded DNA showing hybrid density were unsuccessful. This was due to poor resolution between heavy and light density single-stranded DNA, and the apparent instability of Chlamydomonas DNA to denaturation. Taken together, the results suggest repair, but in general, attempts to identify and characterize dark repair in this organism were unsuccessful. (Diss. Abstr.)

57926 CAROTENOIDS ACCUMULATION AND CHANGES OF CAROTENOID PATTERN OF JAPANESE PERSIMMON BY CATHODE RAY IRRADIATION. **Umeda, Keiji (Food Research Inst., Tokyo); Shiroishi, Masahide. Nippon Shokuhin Kogyo Gakkaishi; 18: No. 4, 161-6(Apr 1971). (In Japanese).**

The effect of cathode ray irradiation on the carotenoids of Japanese persimmon Hiratanenashi and Yotsumizo was investigated. Carotenoid patterns of Yotsumizo varied at different stages of maturity and the chemical composition of the carotenoid group in fully ripe Yotsumizo was hydrocarbon: 15.6%, monol: 19.3%, Diol: 20.9%, diol monoepoxide: 15.4%, diol diepoxide: 24.4%, and polyol: 5.4%. Nearly ripe Yotsumizo were irradiated at 0.1 and 0.3 Mrad and analyzed for total carotenoids and carotenoid patterns at 5, 8, and 12 days after irradiation. Total carotenoid content in 0.1 Mrad samples was higher than that in the non-irradiated samples throughout the experiment and 8 days after irradiation it reached the maximum value of 1.4 times as much as in non-irradiated samples. Total carotenoid content in 0.3 Mrad samples was 1.3 times as much as in non-irradiated samples at 5 days after irradiation, but it decreased rapidly and was less than that of non-irradiated samples subsequently. Carotenoid patterns of 0.1 Mrad samples were similar to those of ripe samples throughout the experiment, but the patterns of 0.3 Mrad samples changed in each analysis. These differences between 0.1 and 0.3 Mrad suggest that irradiation activated normal carotenoid biosynthesis in the case of 0.1 Mrad, while on the other hand, there was a disturbance of carotenoid biosynthesis in 0.3 Mrad. Irradiation at 0.3 Mrad caused a temporary carotenoid accumulation at 5 days after irradiation. (auth)

57927 RADIOSENSITIVITY OF THE RADIATION INDUCED AMINOPTERIN RESISTANT YEAST CELLS. **Munechika, Hirotugu; Kitahara, Takashi; Ishikawa, Nobuyuki; Kamakazu, Kiyomaro; Kiga, Masami (Showa Univ., Tokyo). Nippon Igaku Hoshasen Gakkai Zasshi; 30: No. 6, 518-24(Sep 1970).**

Aminopterin-resistant cells were induced by the x irradiation of yeast cells. Assuming that even a slight disturbance of thymidine mononucleotide (TMP) synthesis caused by radiation was related to the cell damages, it was expected that a correlation exists between radiation resistance and aminopterin resistance. In the present experiments, comparative studies of radiosensitivity were carried out on both original and resistant cells to evaluate this correlation in yeast cells. It was shown that the aminopterin-resistant cells were more radioresistant than the original cells, and that the original cells became more radioresistant by TMP pretreatment. Under these conditions, it was shown that while hydroxyurea or an excess of deoxyuridine mononucleotide (duMP) inhibited the growth of aminopterin-resistant cells, an excess of deoxyadenosine as well as of TMP never inhibited growth. From these evidences, it was proposed that the path way from duMP to TMP was closely related to the radiosensitivity. (auth)

57928 ENZYMATIC REPAIR OF DEOXYRIBONUCLEIC ACID. IV. MECHANISM OF PHOTOPRODUCT EXCISION. **Kushner, Sidney R.; Kaplan, Joan C.; Ono, Howard; Grossman, Lawrence (Brandeis Univ., Waltham, Mass.). Contract AT(30-1)-3449. Biochemistry; 10: No. 18, 3325-34(31 Aug 1971).**

The enzymatic mechanisms controlling the incision and excision of uv-irradiated Escherichia coli DNA have been examined. The uv-endonuclease, which catalyzes the incision step in repair, hydrolyzes a single phosphodiester bond, 5′ to the photoproduct region. This step is associated with the formation of a 3′-phosphoryl group on the DNA and a 5′-hydroxyl group either at, or one nucleotide 5′, to the photoproduct. The release of either nucleotides or photoproducts does not occur at any significant extent under these circumstances. The excision of nucleotides, and those containing photoproducts, from incised DNA is dependent on the unique exonucleolytic properties of a second enzyme, the uv-exonuclease. This enzyme catalyzes the release of approximately seven nucleotides for each phosphodiester bond hydrolyzed during the incision of irradiated E. coli DNA. There are ten nucleotides released during the excision for each incision event of irradiated Micrococcus luteus DNA. The cavity of the excised E. coli DNA is terminated by two phosphoryl groups. A 3′-phosphoryl group arises from incision and after the excision event a 5′-phosphoryl group remains. Chromatographic analyses of the products released during the initial phases of excision revealed that oligonucleotides were liberated and subsequently degraded exonucleolytically by the same enzyme. It is concluded that the primary hydrolytic event during excision is endonucleolytic in nature. Moreover, the distribution of nucleotides 3′ to the photoproduct in the excised fragment from irradiated E. coli DNA is enriched in adenine and thymine containing deoxynucleoside 5′-monophosphates. As the irradiation is intensified this distribution is modified to include cytosine-containing deoxynucleotides. The significance of these findings is discussed. (auth)

57929 RADIATION-INDUCED CHANGE OF ENZYME ACTIVITY DURING BLOCKING OF THE ADRENAL CORTEX. **Khrypchanka, I. P.; Kukulyanskaya, M. F. (Belorussian State Univ., Minsk). Vestsi Akad. Navuk BSSR, Ser. Biyal. Navuk; No. 3, 81-4(1971). (In Belorussian).**

Cholinesterase and hexokinase activity was studied in the cerebral hemispheres and cardiac muscle of rats during fractional dosages of the animals with x-radiation. (13 R + 13 R + 14 R = total of 40 R). In order to define more accurately the effect of radiation the adrenal cortex was blocked with subsequent hormone therapy. The role of the adrenal hormones was considered in connection with the inhibitory effect of radiation, in particular on the brain and heart hexokinase during adrenalectomy. Changes in cholinesterase in these tissues are discussed. (tr-auth)

57930 PULSE-RADIOLYSIS STUDIES OF SOME NUCLEIC ACID FRAGMENTS IN AQUEOUS SOLUTIONS. **Fel, N. S.; Zaozerskaya, L. A.; Dolin, P. I. (Inst. of Electrochemistry, Moscow). Radiat. Eff.; 9: No. 3-4, 145-52(Jun 1971).**

The optical absorption spectra of short-lived products in 1–2×10^{-3} M solutions of pyrimidine bases (PB): thymine (T) and uracil (U) saturated with He and N_2O (pH = 1.2 and 7) have been measured by the pulse radiolysis method. For T and U the spectra of the products of reactions OH + PB, H + PB, and e^-_{aq} + PB are similar in shape and intensity ($E_{380} = 400 \pm 150\ M^{-1}\ cm^{-1}$) and show two maxima (at ~300 and ~380 nm). An additional reaction occurs along C_6 to form $(P\dot{B})OH$ and $(\dot{P}B)H$ radicals; reaction with e^-_{aq} involves fast protonation. C_6 is practically the only place of attack for OH, H, or e^-_{aq}. In solutions of deoxyribose (DOR), the rate constant of the reactions between e^-_{aq} and DOR (it is equal to $(1 \pm 0.5) \times 10^7\ M^{-1}\ sec^{-1}$) has been measured as well as the optical adsorption spectra of the short-lived products of reactions OH + DOR and e^-_{aq} + DOR. From the comparison of the absorption spectra of the short-lived radiolysis products of thymine and thymidine solutions, it has been found that the only place of primary attack on the nucleoside molecule by the OH radical is the base. and e^-_{aq} + DOR. From the comparison of the absorption spectra of the short-lived radiolysis products of thymine and thymidine solutions, it has been found that the only place of primary attack on the nucleoside molecule by the OH radical is the base. A study has been made of uracil solutions in the presence of oxygen. The spectrum of the peroxide radical $UOH\dot{O}_2$ has been obtained ($\lambda_{max} \leq 300$ nm, $E_{300} = (280 \pm 70)\ M^{-1}\ cm^{-1}$) and the rate constant of reaction $\dot{U}OH$ with oxygen has been measured: $(1.6 \pm 0.5) \times 10^9\ M^{-1}\ sec^{-1}$. (auth)

57931 STUDIES OF RADIATION BIOCHEMISTRY IN PLANTS. II. EFFECT OF CHRONIC GAMMA-IRRADIATION ON METABOLISM OF AMINO ACIDS AND SUGARS IN PEA AND WHEAT PLANTS. **Jiracek, V.; Kryzanek, R.; Kostir, J. (Charles Univ., Prague). Rostlinna Vyroba; 16: No. 6, 657-70 (Jun 1970). (In Czech).**

Chronic ^{60}Co γ-irradiation of pea and wheat plants in field experiments affected the content of amino acids and saccharides in above-ground parts and in the roots; this affected not only the irradiated X_0 generation but also filial non-irradiated generations X_1 and X_2. Irradiation of wheat and pea plants affected mainly the content of glutamic acid and of metabolically related amino acids (glutamine, γ-amino-butyric acid, proline) and also serine, threonine, and glycine, arginine, and lysine. Decrease in the content of glutamic acid in the above-ground parts of young pea and wheat plants of generation X_0 was accompanied by increase in the content of γ-aminobutyric acid. A similar relation was found in the above-ground parts of young wheat plants of the X_1 and X_2 generations. This was not the case in pea plants, which pointed to a higher activity of glutamatedecarboxylase. Changes in the content of arginine and lysine affected pea plants significantly only in the X_0 generation while in wheat the effect was found also in X_1 and X_2 generations. Chronic irradiation inhibited the biosynthesis of saccharose in pea plants of all three generations (X_0, X_1, X_2) while in wheat only the X_0 generation was affected. Irradiation also retarded the formation of the glucoside of pisato-

XUM

side in the above-ground parts of peas in all three generations, though in young plants only. Also the transport of fructose from the above-ground parts to the roots of peas and wheat was affected (NSA of Czech)

57932 RADON IRRADIATION OF RAT TISSUE AND ORGANS. Pegel, V. A.; Dokshina, G. A.; Sukhanova, G. A. (Tomsk Univ., USSR). Izv. Sib. Otd. Akad. Nauk SSSR, Ser. Biol. Nauk; 3: No. 15, 128-31(Dec 1970). (In Russian).

The dynamics of oxidative phosphorylation in the rat was studied after irradiation with radon. Rats were injected with 0.2 μCi/gram (radon in equilibrium with its decay products), and then examined at intervals up to 48 hr afterwards for ATP/ADP content in rat tissue and for liver mitochondria. The data indicated that the ATP content was lowered by irradiation by 14 to 62%, the maximum drop being in the spleen within one day. The ATP activity of the liver mitochondria in the rat did not change in the first 24 hr. However, the processes of oxidative phosphorylation of mitochondria which had been removed from the liver were disrupted only 2 to 4 hr after irradiation. (K.S.W.)

57933 CHANGES IN ACTIVITY OF AMINOTRANSFERASE IN MITOCHONDRIA OF TISSUE IN IRRADIATED ANIMALS. Chernoguzov, V. M.; Pikulev, A. T. (Belorussian State Univ., Minsk). Vestsi Akad. Navuk BSSR, Ser. Biyal. Navuk; No. 4, 75-80(1971). (In Belorussian).

The activity of aspartine-aminotransferase and alanine-aminotransferase in mitochondria was investigated from liver tissue, heart muscle, and brain of intact, adrenalectomized rats which had been exposed to 700 R of whole-body x-radiation. Changes in the ratio of activities of free and combined forms of these ferments in mitochondria were investigated at various intervals after the irradiation. Their dependence on the type of tissue as the source of mitochondria was studied. Possible mechanisms were discussed for the individual changes, and for the role of suprarenal hormones. (tr-auth)

57934 NEW IMMUNOGLOBULIN-LIKE MOLECULES IN THE SERUM OF BURSECTOMIZED-IRRADIATED CHICKENS (HEAVY-(μ)CHAIN/IMMUNOELECTROPHORESIS/AGAMMAGLOBULINEMIA). Choi, Young Sung; Good, Robert A. (Univ. of Minnesota, Minneapolis). Proc. Nat. Acad. Sci. U. S. A.; 68: No. 9, 2083-6 (Sep 1971).

A new immunoglobulin-like protein that was found in the sera of bursectomized and irradiated chickens is reported. Unlike IgM and IgG, this protein is apparently made only of heavy chains of IgM and contains no light chains. (auth)

57935 ENZYMATIC REPAIR OF DNA. III. PROPERTIES OF THE UV-ENDONUCLEASE AND UV-EXONUCLEASE. Kaplan, Joan C.; Kushner, Sidney R.; Grossman, Lawrence (Brandeis Univ., Waltham, Mass.). Contract AT(30-1)-3449. Biochemistry; 10: No. 18, 3315-24(31 Aug 1971).

Two enzymes have been purified from Micrococcus luteus which together are responsible for the in vitro excision of photoproducts from uv-irradiated DNA. The first enzyme, uv-endonuclease, catalyzes the formation of single-strand incisions in irradiated duplex DNA. It is inactive on native, irradiated denatured, and unirradiated denatured DNA. The apparent K_m value for irradiated native DNA is equal to 1.25×10^{-5} M at 37° and the pH optimum is between pH 7.0 and 7.5. The UV-endonuclease is stimulated by but not dependent on Mg^{2+}. This enzyme is not inhibited by EDTA or caffeine. Acridine orange is inhibitory at high concentrations (1×10^{-2} M). Based on gel filtration, this enzyme has been assigned a molecular weight of 15,000. The DNA substrate-dose dependency relationship is correlated with uv-endonuclease activity. A direct correlation exists between the number of pyrimidine dimers formed and the number of single-strand breaks which in turn is dependent on the DNA source. The second enzyme, uv-exonuclease, degrades exposed regions of DNA resulting from incision by the uv-endonuclease. The uv-exonuclease hydrolyzes unirradiated and irradiated heat-denatured DNA at equivalent rates and to the same extent but does not attack native DNA or RNA. Unlike most known exonucleases, it is not inhibited by the presence of photoproducts in DNA. The apparent K_m value for irradiated denatured DNA is equal to 4.46×10^{-6} M at 37°. The pH optimum lies between pH 7.0 and 7.5 and the enzyme requires Mg^{2+} for activity. It is inhibited by Mn^{2+}, Ca^{2+}, Zn^{2+}, and EDTA. An unusual feature of this enzyme is the sigmoidal shape of its enzyme concentration curve. The initial lag in this curve can be abolished by certain monovalent cations: K^+, NH_4^+, Na^+, or Li^+. The uv-exonuclease is characterized with respect to its activity on denatured DNA. It degrades this substrate from both the 3′ and 5′ termini in an exonucleolytic manner, yielding as its final degradation product, 5′-mononucleotides. When irradiated denatured DNA is hydrolyzed to completion, the major products are mononucleotides although some tri- and tetranucleotides are also released. Single-stranded polydeoxythymidylic acid, poly $[d(pT)_{200}]$, is degraded entirely to mononucleotides but the digestion products of irradiated poly$[d(pT)_{200}]$ comprise a mixture of mono-, di-, and trinucleotides. (auth)

57936 ADENINE NUCLEOPROTEIDES IN DIFFERENT STAGES OF PHOSPHORYLATION IN LIVER AND KIDNEY OF WHITE RATS SUFFERING FROM RADIATION SICKNESS. Mytareva, L. V. Tr. Leningrad. Khim.-Farm. Inst.; No. 20, 167-72(1969). (In Russian).

The effect of x-radiation on the content and ratio of adenine nucleotides of different degrees of phosphorylation in rat liver and kidney was studied. White rats of both sexes received 1,000 R doses of x-rays at 78 R/min; livers and kidneys were removed at intervals from controls and irradiated animals, and the free adenine nucleotides were determined by paper electrophoresis. Adenosine triphosphate content of the liver had decreased in 2 to 3 hr after irradiation, but was restored in 24 hr, and subsequently fell again. Adenine triphosphate content of the kidney fell in 24 hr. A decrease in all three adenine nucleotides was observed in the liver, but no change occurred in the kidney. (K.S.W.)

57937 STUDY OF LACTATE DEHYDROGENASE ACTIVITY IN CERVICAL CANCER. Iwakura, Tomikazu (Tokyo Medical Coll.). Tokyo Ika Daigaku Zasshi; 27: No. 6, 765-95(Nov 1969). (In Japanese).

Enzyme activity levels in the sera and portio vaginalis tissues from 95 cervical cancer patients were measured before and after ^{60}Co irradiation. Enzyme activity levels in basement epithelia of normal portio vaginalis tissues from 65 non-cancer patients were also studied for comparison. Serum lactate dehydrogenase (LDH) levels in cervical cancer patients were higher than in non-cancer patients. These levels decreased following irradiation at doses of 500 to 1000 R, and increased at doses above 1000 R. Serum activity levels for other enzymes did not differ significantly between the cancer and non-cancer patients, nor was a radiation effect observed as in the case of LDH activity levels. In irradiated tissues, the changes in LDH activity levels were greater in those tissues showing larger histopathological changes. Changes in the histochemical activities in irradiated cancer tissues were great at 1000 R but decreased as the dose was increased above 2000 R. A correlation between decreased histochemical activity and the prognosis for recovery (3-yr recovery rate) was noted. (TSS)

57938 EFFECT OF ACTH ON THE SYMPATHICO-ADRENAL SYSTEM IN DEALING WITH RADIATION SOURCES. Kogan, I. A. Gig. Tr. Prof. Zabol.; No. 9, 24-6(Sep 1971). (In Russian).

The question as to the influence exerted by ACTH on the medullar layer of the adrenals has not been dealt with sufficiently in literature sources. This study covered the effect of ACTH on the excretion of catecholamines in persons dealing with various sources of ionizing radiation. Epinephrine and norepinephrine were determined after V. O. Osinskaya as modified by Baru. A total of 81 subjects, including 17 controls, were examined. Depending upon the summary irradiation dosage, all examinees were divided into four groups, viz. from 5 to 30 R; from 30 to 70 R; from 70 to 150 R; and from 150 to 400 R. In healthy persons, introduction of ACTH brought about on day 2 to 3 of investigation an increase of the epinephrine and a fall of the norepinephrine excretion. With increased radiation dose, the excretion of catecholamines diminished in all periods of the study (weakening of compensatory mechanisms). (auth)

57939 ULTRAVIOLET RADIATION EFFECTS ON ISOLATED NERVE FIBERS. Lieberman, Edward M. (Wake Forest Univ., Winston-Salem, N. C.). Advan. Biol. Med. Phys.; 13: 329-50 (1970).

Nerve-muscle preparations and isolated axons from the walking leg of the blue crab, Callinectes sapidus, were used in the experiments. Action spectrum data suggest that the target of irradiation is the excitable membrane. It is thought that the effects of ultraviolet radiation are on the inner and outer protein layers of the axonal membrane. Evidence from the studies indicates that a nucleotide-like molecule is directly involved in excitability characteristics of nerve. It was concluded that the structural and functional components of the membrane system responsible for the operation of the excitability system are common to the transport ATPase and ATP dependent Ca^{2+} binding properties of the membrane. (H.L.W.)

57940 EFFECT OF GAMMA RADIATION ON THE PHOSPHOLIPASE A ACTIVITY OF THE STICKER SARCOMA. Lloveras, Jacques; Douste-Blazy, Louis (Univ., Toulouse). Compt. Rend., Ser. D; 272: No. 20, 2641-3(17 May 1971). (In French).

The Sticker sarcoma of the dog contains an A phospholipase acid (optimum pH 4.5) which is localized principally in the lysosomes and mitochondria; it is present in very small quantities in the microsomes and absent from the soluble fraction. Gamma irradiation (500 rads) enhanced this enzymatic activity after the fifteenth minute in mitochondria, lysosomes, and microsomes and induced its appearance in the soluble fraction. (auth)

57941 STUDIES OF RADIATION BIOCHEMISTRY IN PLANTS. I. CHRONIC EFFECT OF GAMMA IRRADIATION ON PHOSPHORUS METABOLISM IN PEA AND WHEAT. **Jiracek, V. (Charles Univ., Prague); Kryzanek, R.; Votruba, I.; Kostir, J. Rostlinna vyróba; 16: No. 6, 645-56(Jun 1970). (In Czech).**

The effect was studied of chronic γ-irradiation on the dynamics of phosphorus-containing substances in pea and wheat plants in field experiments. The content of various fractions of phosphorus was examined in both the irradiated X_0 generation and in two non-irradiated F-generations (X_1 and X_2). Ionizing radiation stimulated the intake of phosphorus. This resulted in an increased total P content, especially in the above-ground parts of pea and wheat plants of generation X_0. The content of phosphorus insoluble in ethanol and of phosphorus soluble in acids was increased. The content of both fractions of phosphorus increased also in wheat roots while it decreased in pea. The content of phosphorus soluble in ethanol (represented mainly by phospholipides) decreased in the above-ground parts and in the roots of generation X_0 of wheat, while it increased in pea, except for the roots of some old plants. The content of nucleic acids markedly increased in the above-ground parts of wheat of the X_0 generation, whereas its increase in pea was less significant. It decreased in the roots of both pea and wheat. The content of RNA increased significantly in the above-ground parts of both young and old wheat plants, while in pea it increased only in young plants. The content of DNA mostly decreased in the above-ground parts of young plants of both pea and wheat. Changes induced by ionizing radiation were less marked in the X_1 and X_2 F-generations of both pea and wheat, in which reparation processes had already started. (NSA of Czech)

57942 EFFECTS OF ULTRAVIOLET AND VISIBLE LIGHT ON NERVE FIBERS AND CHANGES IN OPTICAL PROPERTIES DURING NERVOUS ACTIVITY. **Tasaki, Ichiji (National Inst. of Mental Health, Bethesda, Md.). Advan. Biol. Med. Phys.; 13: 307-27(1970).**

The effects of uv and visible light on the electrophysiological activity of the nerve fiber are reviewed. Unstained nerve fibers strongly absorb uv shorter than about 300 nm wavelength and are injured by the absorbed uv. Nerve fibers stained with various dyes are sensitized to the light absorbed by the dyes. The macromolecular approach to the process of nerve excitation is reviewed. The subunits, of which the nerve membrane is composed, are considered to exist in either one of the two distinct conformational states. Transition of a subunit from one state to the other is brought about by a cooperative ion-exchange process involving univalent and divalent cations occupying the anionic sites of the membrane macromolecules. The importance of the eddy (local) currents in the process of nerve excitation is stressed. The molecular basis of the process of nerve excitation is examined by staining nerve fibers with various dyes. It is possible to detect changes in the intensity of fluorescence during the action potential. The dye technique offers powerful means of elucidating physicochemical properties of the nerve membrane. The biochemical processes leading to the photosensitization effect of dyes are not clear at present. (auth)

57943 REPAIR OF DNA IN MAMMALIAN CELLS. **Painter, R. B. (Univ. of California, San Francisco). Curr. Top. Radiat. Res.; 7: No. 1, 45-70(Sep 1970).**

Several kinds of DNA repair are known to occur in mammalian cells. Of these, single-strand rejoining and repair replication have been most intensively studied. It now seems probable that, after x-irradiation, the rejoining of single-strand breaks involves repair replication. On the other hand, the first step in excision repair after uv-irradiation is the formation of a single-strand break by enzymes within the cell. Therefore, these two phenomena are probably closely related and in many cases may reflect the same repair system. A relatively newly discovered repair system, recombination repair, occurs in DNA made after damage has occurred. This may be of greater importance in mammalian cells after uv-irradiation than is excision repair, since many mammalian cells apparently do not excise dimers. Even this repair system, however, probably utilizes some or all of the same enzymes that operate in excision repair. These repair systems undoubtedly are important in recovery from potentially lethal and sublethal damage in mammalian cells, but their exact roles are still not clear. Photoreactivation occurs in marsupials but apparently not at all in cells from placental animals. (auth)

57944 AUTORADIOGRAPHIC STUDY OF THE EFFECT OF X RAYS ON DNA AND RNA SYNTHESIS DURING SEGMENTATION AND GASTRULATION OF PLEURODELES WALTII MICHAH. **Alexandre, Henri (Univ, Brussels). Arch. Biol. (Liege); 81: 139-62(1970). (In French).**

Young pleurodele embryos were irradiated at the following stages: 2 to 4 blastomeres, morula, blastula and gastrula. The use of nucleic acid precursors administered by microinjection shows that x-rays applied to cleaving eggs inhibit DNA replication and mRNA synthesis in proportion to the dose given, and that this results in an arrest of development of the advanced blastula stage. The metabolic pathway leading to the incorporation of ^{3}H uridine into DNA is extremely radiosensitive in young embryos. It was also demonstrated that the lower level of radiosensitivity observed in gastrulas results in a higher resistance to x-rays of the synthesis of DNA from thymidine: the metabolic pathway whereby DNA is synthesized by incorporation of uridine is still very much altered by irradiation. (auth)

57945 PRELIMINARY STUDIES ON THE CHANGES IN THE ELECTROPHORETIC MIGRATION PROFILE OF THE PROTEINS IN HUMAN SALIVA DURING ANTI-PLASTIC RADIATION THERAPY. **Pini Prato, G. (Univ., Florence). Riv. Ital. Stomatol.; 25: No. 11, 1042-6(Nov 1970). (In Italian).**

The effect of radiation therapy on the electrophoretic pattern of human salivary proteins has been studied in 20 patients, subjected to radiation for antiblastic therapy. A loss of some cationic fast migrating components of the salivary proteins has been observed in 3 cases. This finding is discussed briefly in connection with the problem of the effect of radiation on animal cells. (auth)

57946 INVESTIGATIONS ON IMMUNITY DEVELOPED IN CHICKENS AGAINST ASCARIDIA GALLI USING IRRADIATED EGGS OF THIS HELMINTH. **Deo, P. G.; Sokolic, A.; Gangadhara Rao, Y. V. B. (Indian Veterinary Research Inst., Izatnagar). Indian J. Anim. Sci.; 41: No. 4, 306-10(Apr 1971).**

Double vaccination—first at 20 days of age with 500 irradiated eggs of A. galli and second at 35 or 50 days with 1,000 such eggs—induced strong immunity against the challenges with 1,000 normal (non-irradiated) eggs at 50, 65, 80 and 95 days. The eggs were irradiated at 10 kR of gamma-rays delivered from ^{60}Co source. The immunity developed by vaccinations at 20 and 50 days appeared steadier than that produced by vaccinations at 20 and 35 days. Irradiation of eggs completely inhibited the development of male worms. Such vaccinations improved the weight-gain in chickens. Various immunization schedules are discussed briefly. (auth)

57947 (CONF-710501-35) ERROR ANALYSIS OF ECOLOGICAL MODELS. **O'Neill, R. V. (Oak Ridge National Lab., Tenn.). [1971]. 32p. Dep. NTIS.**

From third national symposium on radioecology; Oak Ridge, Tenn. (10 May 1971).

Systems analysis techniques are valuable in the analysis of radionuclide kinetics in ecosystems. However, the art of systems modeling is relatively new to ecology and few guides are available for constructing ecological models. As a result, untested hypotheses are sometimes involved in model development. For example, it may be difficult to predetermine optimal model complexity, i.e., the number of state variables or compartments to be included in a model for acceptable accuracy. The hypothesis that greater complexity leads to greater accuracy was tested by analyzing the total uncertainty accompanying a model prediction. In general, systematic bias, resulting from abstracting the system into a few variables, is inversely related to complexity. However, there is a concomitant increase in uncertainty due to measurement errors on individual model parameters. As more parameters are added to the model, they must be quantified in field and laboratory experiments which are never error-free. If these measurement errors are promulgated through a simulation, they contribute to uncertainty in model predictions. By applying Monte Carlo simulation techniques, it was possible to account explicitly for each component of the total uncertainty. Particular attention was paid to the balance between systematic bias and measurement errors. This analysis indicated that the gain in precision from increasing model complexity is not as consistent an outcome as might be expected. Results appear valid for a wide range of modeling applications. (auth)

57948 (SWRHL-85-r) RADIONUCLIDE STUDIES WITH DAIRY COWS FOLLOWING TWO PLOWSHARE EXPERIMENTS. Black, Stuart C.; Bretthauer, Erich W.; McNelis, David N. (Western Environmental Research Lab., Las Vegas, Nev.). Sep 1971. 32p. Dep. NTIS.

Baled hay was placed on the ground in the predicted trajectory of the effluent from the two Plowshare cratering tests, Cabriolet and Buggy. After contamination, the bales were collected and measured amounts of the hay were fed to groups of dairy cows. As compared to similar experiments following other cratering tests, the amount of ^{131}I transferred to milk was about one-third, and the time to peak milk concentration and effective half-life in milk were longer. The ratio of peak ^{131}I concentration in milk to the peak concentration in hay was also much less than that observed in previous tests. These facts suggest that the ^{131}I in the debris from these two tests was less biologically available to the cow than it was in previous tests. For Project Buggy, the transfer of ^{187}W to milk was also measured. Less than 0.5% of the tungsten ingested with the hay was secreted in milk and the measured half-time in milk was about 2.5 days. (auth)

57949 PHOSPHORUS FEEDING OF BUCKWEAT AND YELLOW LUPINE IN PURE AND MIXED PLANTS. Zabyalendzik, S. F. (Inst. of Experimental Botany, Minsk). Vestsi Akad. Navuk BSSR, Ser. Biyal. Navuk; No. 3, 25-9(1971). (In Belorussian).

The seasonal rhythm and uptake rate of labelled phosphorus were studied in buckwheat and lupine under conditions of growth in pure and mixed stands. Buckwheat absorbed phosphorus faster than lupine by a factor of two in pure stands, and by a factor of seven in mixed. Maximum ^{32}P uptake was noted in the budding stage of buckwheat, but in lupine the stalk-development phase. Minimum ^{32}P uptake occurred in buckwheat during ripening; in lupine during the bean stage. (tr-auth)

57950 ^{32}P TRANSMISSION FROM PLANT TO PLANT. Min'ko, I. F. (Inst. of Experimental Botany, Minsk). Vestsi Akad. Navuk BSSR, Ser. Biyal. Navuk; No. 3, 20-4(1971). (In Belorussian).

Plant-to-plant transmission of ^{32}P was studied in pure and blended plants of vetch and oats. Vetch showed uptake of ^{32}P through both leaves and roots, although the root system was more effective. Transmission of ^{32}P in pure vetch was twice as effective as in pure oats. Vetch-to-oats transmission was 1.5 to 2 times better, and from oats-to-vetch it was lowered by 20 to 25% in comparison to the pure crop. Transmission dropped with increasing age of the vetch or oat plants. (tr-auth)

57951 (COO-1747-6) RADIATION INDUCED DNA SYNTHESIS IN THE POLYTENE CHROMOSOMES. Valencia, Juan I.; Plaut, Walter (Wisconsin Uni.v., Madison. Dept. of Zoology). [1970]. 18p. Dep. NTIS.

Salivary gland chromosomes of Drosophila melanogaster were irradiated with 1,000 to 100,000 R x rays and a dose of 1800 ergs/mm^2/sec of ultraviolet. Following incubation in tritiated thymidine, nuclei were analyzed for frequency of labeled nuclei, proportion of discontinuous and continuous labeling, frequency of labeling at specific loci and frequency of joint labeling at normally correlated loci, iso-labeling at homologous loci in unpaired regions of homologous chromosomes, and distribution of autoradiographic grains across versus along the chromosome axis. The results showed that a range of doses of x rays and ultraviolet radiation induced a kind of DNA synthesis in the salivary gland nuclei that could be detected by the incorporation of tritiated thymidine and appears to be closely related to the phenomenon of repair replication in bacteria and mammalian cells. The effect was induced and observed in the extended interphase polytene chromosomes at highly localized single spots distributed randomly throughout the euchromatic chromosome region. (H.L.W.)

57952 (LBL-28) HEAVY-ION-INDUCED SINGLE- AND DOUBLE-STRAND BREAKS IN ϕX-174 REPLICATIVE FORM DNA. Christensen, Ralph Chresten (California Univ., Berkeley. Lawrence Berkeley Lab.). Aug 1971. Contract W-7405-eng-48. 106p. Dep. NTIS.

Radiation damage in ϕX-174 Replicative Form I (RF I) DNA was measured as a function of linear energy transfer (LET), using radiation qualities ranging from that of ^{60}Co gamma rays to that of highly stripped argon nuclei of average initial charge +16.5 and maximum energy 7.4 MeV/nucleon. Irradiations were performed at room temperature in a highly radioprotective broth (4% Difco Nutrient Broth, 2% AET, 0.01 M Tris, pH 8.0) to minimize free radical effects. With the exception of deuterons, all ion beams terminated in the continuously mixed samples. Samples were assayed for relative proportions of RF I (supercoil), RF II (open coil), and RF III (linear) DNA configurations, using neutral sucrose gradient sedimentation of tritiated thymidine-labeled ϕX-174 RF DNA. Viability of bulk and gradient-separated samples was determined using a spheroplast assay. Total viability radiosensitivity of irradiated samples remained approximately constant over nearly the entire LET range investigated. RF I and RF II specific viability radiosensitivity measures (indices of non-break lethal damage and non-break lethal damage plus single-strand break lethal damage, respectively) dropped slowly with increasing LET, but accounted for 50% or more of lethal events at all LETs. The single-strand break event radiosensitivity also decreased slowly with increasing LET, ranging from 0.34 ± 0.04 break events/Mrad/10^6 daltons for ^{60}Co gamma ray irradiation, to 0.12 ± 0.01 break events/Mrad/10^6 daltons for argon nuclei of average LET 2.4 × 10^4 MeV-cm^2/g. Low-LET alkaline sucrose gradient configurational determinations of total radiation-induced DNA break events yielded consistently greater values, indicating the possible presence of alkali-labile bonds in damaged DNA. At low LET, double-strand DNA breaks were produced at a rate of 0.013 ± 0.003 breaks/Mrad/10^6 daltons, rising to a maximum rate of 0.061 ± 0.008 breaks/Mrad/10^6 daltons at about 5500 MeV-cm^2/g. Double-strand DNA breaks, which are lethal in this biological system, accounted for less than 10% of the total lethality at low LET, rising to 30 to 50% of the total lethality at high LET. (auth)

57953 EFFECTS OF LOW FREQUENCY VIBRATIONAL STRESS ON THE GENOME OF DROSOPHILA MELANOGASTER. Saitta, Frank P. Providence; Univ. of Rhode Island (1970). 89p. University Microfilms Order No. 71-12,802.

Thesis.

The genetic effects of low frequency vibrational stress on Drosophila melanogaster (the fruit fly) were investigated through an analysis of the incidence of dominant lethal, recessive lethal and multigenic mutations. Increases in dominant lethals were observed when males were vibrated at 100 Hz, amplitude 0.5″ (510 g's). The intensity of this effect seemed to be a function of the duration of the treatment. Likewise, subvital and polygenic mutation effects were significantly greater in treated groups than in controls. Experiments were also carried out in an attempt to ascertain the possible mutagenic interaction of gamma irradiation and vibration. The data indicates an antagonistic relationship, i.e., sex-linked lethals and somatic effects were less pronounced in progeny of flies that were irradiated (4000 R) and vibrated (100 Hz; amplitude 0.5″) than in progeny of flies subjected to the 4000 R of irradiation only. Physiological responses, via increased mating activity, were also found to be stimulated in males by vibrational stress. (Diss. Abstr.)

57954 PHOTOREACTIVATION OF MUTATIONAL DAMAGE PRODUCED BY THE INTERACTION BETWEEN DEB AND UV IN NEUROSPORA. Rannug, J. Ulf (Dept. of Genetics, Edinburgh). Mol. Gen. Genet.; 111: No. 2, 194-6(1971).

The mutational damage produced by the interaction between DEB-pretreatment and uv-posttreatment in a Neurospora strain, ad-3A (38701) inos (37401), is photoreactivable. It may thus be concluded that the interaction mutants possess characteristics of uv-induced ones. (auth)

57955 GENETIC REPAIR AND THE SYNTHESIS OF NITRATE REDUCTASE IN USTILAGO MAYDIS AFTER UV IRRADIATION. Resnick, Michael A.; Holliday, Robin (National Inst. for Medical Research, London). Mol. Gen. Genet.; 111: No. 2, 171-84 (1971).

The ability of uv-sensitive (uvs$^-$) and wild type (uvs$^+$) strains of Ustilago maydis to synthesize the inducible enzyme nitrate reductase (NR) was examined following uv-exposure. Low doses of uv-irradiation prior to induction inhibit to a greater degree the first appearance of NR in uvs$^-$ as compared to uvs$^+$ strains; in addition, the exponentially increasing rates of NR synthesis are much less in the uvs$^-$ strains. It is concluded that the damage is primarily pyrimidine dimers in the DNA, since the uv-induced effects are largely removed by photoreactivation. At all but the lowest dose, at least one dimer on the average appears to be induced per functional strand of the nitrate reductase gene. If cells are irradiated after being suspended in NR inducing medium, enzyme synthesis is temporarily stopped or considerably reduced indicating that the mRNA has a short half-life and that transcription is inhibited. However, it resumes within 20 min after exposure which suggests that alteration or removal of damage is very rapid. Unrepaired or improperly repaired dimer regions lead to the production of altered enzyme as shown by the presence of enzyme cross reacting material and the heat lability of NR in crude cell extracts. It is proposed that the synthesis of altered enzyme may be due in part to transcription past unrepaired or improperly repaired dimer regions in the nitrate reductase gene. (auth)

57956 CONJUGAL TRANSFER OF UV-DAMAGED F-PRIME SEX FACTORS AND INDIRECT INDUCTION OF PROPHAGE λ. George, Jacqueline; Devoret, Raymond (CNRS, Gif-sur-Yvette, France). Mol. Gen. Genet.; 111 No. 2, 103-19(1971).

Conjugal transfer of uv-damaged F-prime sex factors was investigated in connection with indirect induction. Using donors and recipients of different ability to perform pyrimidine dimer excision and/or recombination repair, it was found that: Transfer of uv-irradiated F-prime DNA to the recipient cell is unaffected by the presence of pyrimidine dimers. The efficiency of transfer does not decrease even at rather high UV doses given to the donor in which, as a result of irradiation, chromosome replication is strongly inhibited. Transfer of the signal responsible for indirect uv induction can be correlated with the transmission of the uv-damaged sex factor from donor to recipient. In the recipient cell, the sex factor DNA does not undergo excision repair but can be repaired by recombination. It is inferred that the transferred DNA structure is not fully double-stranded. In conclusion, indirect uv induction occurs in a λ-lysogenic recipient upon transmission of a uv damaged replicon which carries stabilized lesions as a consequence of its conjugal transfer. (auth)

57957 X RAY-INDUCED MUTATIONS OF THE GENETICALLY-DETERMINED MELANOMA SYSTEM OF XIPHOPHORIN FISH. Anders, Annerose; Anders, F.; Pursglove, Diana L. (Justus-Liebig Univ., Giessen, Ger.). Experientia; 27: No. 8, 931-2 (15 Aug 1971).

Several crosses were made between irradiated and nonirradiated fish and variations in the macromelanophore gene expression in the offspring are tabulated. Results indicated that the increase in macromelanophore gene expression was due to mutations in a very large number of widely distributed chromosomal genes. The genotypes resulting from the crosses revealed a synergistic effect of x irradiation and hybridization on the increase of macromelanophore gene expression. (H.L.W.)

57958 KINETICS OF REJOINING OF SINGLE-STRAND BREAKS INDUCED BY IONIZING RADIATION IN DNA OF HUMAN LYMPHOCYTES. Donlon, Terrence Edward. Los Angeles; Univ. of California (1971). 47p. University Microfilms Order No. 71-21,325.

Thesis.

The kinetics of repair of single-strand breaks induced by 6 MeV electrons in DNA of human lymphocytes was studied using sedimentation-velocity analysis of molecular weights. The rate of repair was found to be rapid initially and essentially constant for the first 20 to 30 minutes of incubation at 37°C; it then declined markedly. For the rapid initial process the activation energy over the temperature range of 22 to 37°C was 19.1 ± 0.4 Kcal/mole, the temperature at maximum rate was about 40°C, and the Michaelis-Menton constant, estimated from the rate at $V_{max}/2$, was approximately 20 Krads. These results are similar to those characterizing the rate-limiting step for unscheduled DNA synthesis stimulated by x-rays. Moreover, the number of breaks per rad and the maximum rate of incorporation of nucleotides per cell found in this study are similar respectively to the number of lesions per rad and the maximum rate of incorporation of nucleotides per cell found in studies of unscheduled DNA synthesis. It seems likely, therefore, that the repair of single-strand breaks and the incorporation of nucleotides in unscheduled DNA synthesis share the same rate-limiting enzymatic step. (Diss. Abstr.)

57959 EFFECT OF OXYGEN ON SOMATIC CROSSING OVER IN THE X-CHROMOSOME OF DROSOPHILA MELANOGASTER. Stauffer, Henry Hans. Berkeley, Calif.; Univ. of California (1970). 271p. University Microfilms Order No. 71-20,914.

Thesis.

The influence of oxygen on the frequency of somatic crossing over in the X-chromosome of Drosophila melanogaster was studied under a variety of experimental conditions. A series of experiments was carried out under standard conditions, in air and at a temperature of 25°C, spaced at intervals over a period of eighteen months. D. melanogaster was found to be capable of tolerating a wide range of oxygen levels, developing in an apparently normal manner, from zygote to adult, in atmospheres containing as low a concentration of oxygen as seven and a half percent or one as high as ninety percent. Flies raised in seventy to ninety percent oxygen were noted to have significantly more mosaic spots than those which developed in air, thus showing that oxygen by itself can increase the rate of somatic recombination. First instar larvae of the two genotypes were irradiated with 1326 R (at a dose rate of 102 R per minute) in gas mixtures, of air and nitrogen or air and oxygen, whose oxygen content ranged from complete anoxia to one hundred percent. A rapid rise in the number of mosaic spots between the larvae x-rayed in nitrogen and those treated in air was observed. At higher oxygen tensions there occurred a flattening of the response curve. These findings demonstrate the existence of an oxygen effect for somatic recombination in the cells which form the abdominal tergites of D. melanogaster. The relative frequencies of the types of mosaic spots were unchanged by life-long exposures to concentrations of oxygen greater than that of air but were altered by the x-ray treatments, with an increase in the percentages of twin and yellow-singed spots in the trans and cis genotypes, respectively, being found. The data suggest that there may be basic differences between oxygen and x-rays with respect to the mechanisms by which somatic recombination is produced. X-raying first-instar larvae, with the mutant genes in the trans position, in air or oxygen and then post-treating with nitrogen created a substantially higher number of mosaic spots than were found when larvae, after being similarly irradiated, were placed into air or oxygen. This result perhaps is caused by the disruption of an oxygen dependent repair process. (Diss. Abstr.)

57960 NEUTRON-INDUCED MUTANTS OF PISUM SATIVUM AND THEIR COMPARISON WITH X-RAY-INDUCED GENOTYPES. Gottschalk, W.; Chen, R. (Univ., Bonn). Angew. Bot.; 154: 325-42(1970). (In German).

One hundred and sixty-one mutants of Pisum sativum were selected after irradiation of dry seeds with neutrons. The following results were obtained: The chimerical nature of the M_1 plants already known from x-ray treatment was confirmed after neutron irradiation. The proportion of lethal mutants was considerably lower following neutron treatment than with x-rays. Only 14% of all neutron-induced mutants were lethals, while the corresponding proportion in our x-ray experiments was 27%. In the same trial some genes mutated several times; futhermore, at least 11 neutron-induced mutants were identical with genotypes obtained by x-ray irradiation. It can be concluded, that many genes of the Pisum genome show the same response to the action of neutrons and x-rays. The seed production of the fertile mutants varied between 200 and 10% of the original line. Some mutants with a high seed yield could be of interest for mutation breeding. (INIS)

57961 EFFECT OF RADIATION ON SMALL COMPETING POPULATIONS OF DROSOPHILA MELANOGASTER. IV. CHANGES IN LONGEVITY. Dyer, K. F. (Medical Research Council, Harwell, Eng.); Lamb, Marion J. Genetics; 68: No. 4, 559-69(Aug 1971).

Two populations, one of which was homozygous for the marker gene light and the other for the marker gene straw but which was otherwise genetically almost identical, were allowed to compete in the same population cages for 25 successive generations. Twenty-five males and 25 virgin females of each phenotype were used as parents for each generation and at the beginning of each generation the straw parents were irradiated with 1500 R x rays. The longevities of virgin females from the light and straw populations and the heterozygotes between them were measured and compared. Comparisons were also made with the lifespans of females from control cages in which neither population had received any irradiation. The lifespans of all three genotypes from the cages in which the straw population was irradiated were consistently less than those of the corresponding genotypes from the control cages. This difference was thought to be due to the reduction in larval density caused by the induction of dominant lethals in the irradiated straw population since larval density and adult longevity are known to be positively correlated. When allowance was made for this indirect effect of irradiation it was concluded that, although the level of genetic damage in the irradiated population was high, the direct effect of this on longevity was very small. At generation 12 the mean lifespan of flies from the irradiated straw population was only about 5% less than that of the controls and this percentage did not increase in subsequent generations. Prior to generation 12 there was some evidence of a slight increase in lifespan in the irradiated straw population. These small changes in longevity paralleled the changes found in pre-adult competitive ability. (auth)

57962 GENE AND CHROMOSOMAL BEHAVIOR IN A PARASITIC WASP. Leach, Peggy Ann. Orono, Maine; Univ. of Maine (1970). 102p. University Microfilms Order No. 71-20,270.

Thesis.

A study was made of two forms of Muscidifurax raptor (Girault and Sanders), one reproducing by male parthenogenesis (arrhenotoky) the other by female parthenogenesis (thelytoky). In the thelytokous form, meiosis is entirely normal, n = 5. Diploid restoration (2n = 10) occurs by endomitosis during the first cleavage division. Thus, females are homozygous for each locus. This cytological demonstration of female homozygosity is supported by x-ray studies in which all visible mutants appeared in the immedi-

XUM

ate progeny of irradiated females. To determine the applicability of the Habrobracon scheme of sex determination to Muscidifurax, matings were made within the arrhenotokous stock of red-eyed females and black-eyed males. The progeny were examined for black-eyed, biparental males, none of which was found. A comparative study of the effects of x rays on arrhenotokous virgin female production and thelytokous female production was performed, using dosages ranging from 1000 to 9000 R. Correlations and regressions were done on both sets of data. Regression coefficients of the two lines proved to be homogeneous; thus, the two types of experimental animals were behaving in the same manner to the x rays. When comparisons were made point-for-point, it was found that the x rays reduced progeny production to a significantly larger degree in the arrhenotokous form than in the thelytokous form. The difference could be explained on the basis of differential behavior, lethal versus non-lethal, of minor, terminal deletions. Seven gynandromorphs, each with male antennae and an ovipositor, appeared during this study. Four were progeny of irradiated virgin females from arrhenotokous stock and would not be expected to show female structures. Their presence can be explained by endomitotic diploidization of posterior cleavage nuclei subsequent to cleavage I. It was suggested that these gynandromorphs may demonstrate a close relationship between the arrhenotokous and the thelytokous form of reproduction in this wasp. (Diss. Abstr.)

57963 RADIATION AND CHROMOSOMAL ABNORMALITY. **Sugahara, Tsutomu (Kyoto Univ.). Rinsho Kagaku; 6: No. 5, 611-15(May 1970). (In Japanese).**

In the study of chromosomal abnormalities produced by ionizing radiation, human peripheral lymphocytes are used. The methods of observation, kinds of abnormalities observed, exposure dose, and mechanism of lymphocyte turnover are discussed. The abnormality in incubated peripheral lymphocytes produced by radiation is an unstable type of aberration, but there are still unsolved problems such as the increase in heteroploidy and the variation in chromosomal aberrations after irradiation of the human body. Unstable types of abnormality were seen in peripheral lymphocytes following exposures to a low dose, internal exposure, and atomic bomb radiation in Japan and the Bikini atoll. These can be examined and detected over a long period of time. Chromosomal aberration can be used as a means for evaluating biological doses, and could offer a clue to the life span and turnover of lymphocytes, but the phenomenon of chromosomal aberration has not yet been elucidated in detail. (Japan)

57964 EFFECT OF HYGROMYCIN B AND STREPTOMYCIN ON ACTINOMYCES HYGROSCOPICUS VARIABILITY INDUCED BY X-IRRADIATION. **Tsyganov, V. A.; Pronina, M. I.; Kvitko, K. V. (Research Inst. of Antibiotics, Leningrad. Univ. of Leningrad). Genetika; 7: No. 9, 160-8(Sep 1971). (In Russian).**

Effects of hygromycin B and streptomycin on x ray induced variability of Actinomyces hygroscopicus strains differing in their resistance to hygromycin B were studied. It was shown that irradiation at a 60 kR dose of strains 33-a and 5096 revealed higher or equal viability of spores as compared to that of original strain 33. Over the range of 320 to 840 kR, the cultures adapted to hygromycin B proved to be more resistant to the lethal effect of the antibiotics studied on radioresistance of Act. hygroscopicus. The higher the resistance of the actinomycete to hygromycin B, the lower was variability of radioresistance. It was noted that the process of mutation in Act. hygroscopicus, induced by x irradiation, was modified by antibiotics including hygromycin B produced by the given culture. An increase of mutation rate was observed in sensitive strain 33 when its irradiated cells were grown in a medium containing a non-lethal concentration of hygromycin B. Strain 33-a, possessing a moderate resistance to hygromycin B, occupied an intermediate position as concerned the degree of modification of the mutation process under the action of antibiotics mentioned. Highly resistant strain 5096 did not reveal an essential increase of the rate of morphological mutations. When Act. hygroscopicus was grown in a medium containing a non-lethal dose of streptomycin, a protective effect was noted expressed in a marked decrease of the rate of x-ray-induced morphological mutations in Act. hygroscopicus. (auth)

57965 INFLUENCE OF 5-BROMOURACIL ON THE SENSITIVITY OF Her$^+$- AND Her$^-$- BACTERIA TO THE LETHAL AND MUTAGENIC EFFECT OF UV-LIGHT. **Kondrat'ev, Yu. S.; Skavronskaya, A. G. (Inst. of Epidemiology and Microbiology, Moscow). Genetika; 7: No. 9, 149-54(Sep 1971). (In Russian).**

The effect of substitution of thymine on 5-bromouracil (5-BU) in DNA of Hcr$^+$ and Hcr$^-$ cells on their uv-sensitivity was studied. It was found that 5-BU-substitution sensitized the strains having equal level of thymine requirement to the lethal action of uv-light to the same extent irrespective of their hcr genotype. The effect of this sensitization was probably due to the disturbance in the repair of single-strand breaks. Such breaks may appear as a result of the direct action of uv-light on 5-BU-containing DNA or may be a consequence of the action of repair enzymes. Incorporation of 5-BU into the bacterial DNA leads to the enhanced frequency of direct mutations and reversions induced by uv irradiation. The enhanced frequency of uv-induced mutations in 5-BU-substituted bacteria appears to be a result of errors during repair and/or semiconservative replication of DNA containing nonexcisible photoproducts of 5-BU. As in the case of killing, the sensitization to the mutagenic action of uv light is not related to hcr genotype. The lower sensitizing effect of 5-BU substitution on the mutagenic action of uv light as compared with the sensitizing effect on the lethal action seems to be due to different mechanisms of uv-induced death and mutagenesis in 5-BU-substituted cells. (auth)

57966 STUDY OF COMPETITIVE CAPACITY OF DROSOPHILA MELANOGASTER INDIVIDUALS HETEROZYGOUS FOR X-RAY INDUCED MUTATIONS. **Lur'e, T. L.; Gol'zberg, K. L.; Vorobtsova, I. E. (Central Research Inst. of Roentgenology and Radiology, Leningrad). Genetika; 7: No. 9, 84-9(Sep 1971). (In Russian).**

It was observed that larvae of Drosophila melanogaster heterozygous for x-ray induced mutations competed for food less successfully than larvae of normal flies. This conclusion was inferred from a more intense elimination of test-line larvae as compared to those of the control normal line in mixed cultures. It was established, however, that in pure cultures the survival in comparable groups depended on the density of the larval population. When the larval population was sparse, heterozygous individuals survived better than the control wild-type population, and vice versa in cases of a high density of the larval population. Apparently this is associated with the different character of distribution for viability of individuals of comparable groups. (auth)

57967 MUTAGENIC EFFECTS OF DIFFERENT TYPES OF RADIATION ON GERM CELLS OF MALE MICE. VI. GENETIC RADIOSENSITIVITY OF GERM CELLS IN EMBRYOS AND NEWBORNS. **Fazylov, U. T.; Pomerantseva, M. D. (Inst. of General Genetics, Moscow). Genetika; 7: No. 9, 68-75(Sep 1971). (In Russian).**

The frequency of reciprocal translocations and dominant lethal mutations were used as indices of radiosensitivity. The dose-effect dependence for the yield of reciprocal translocations in germ cells of newborn and spermatogonia of adult mice was shown to be linear within the range of 20 to 400 R doses of x rays. Genetic radiosensitivity of gonocytes of newborns was one third of that of spermatogonia. The frequency of reciprocal translocations in males developed from embryos subjected to x irradiation at a 20 R dose was higher than that in adult mice irradiated at the same dose. In cases of irradiation of embryos at doses of 50 and 100 R, the translocation yield was lower than in adult mice irradiated at the same doses and was similar to the mutation rate in newborns. The study of dominant lethal mutation rate in germ cells of male mice irradiated at different ages did not reveal any difference in their genetic radiosensitivity. The lower frequency of translocations in germ cells of embryos and newborn male mice at 50 R and higher doses is probably due to a higher selective death-rate of primary germ cells. (auth)

57968 DIFFERENCES IN RADIATION-INDUCED LESIONS OF CHROMOSOMES OF THE EMBRYONIC MERISTEM OF CREPIS CAPILLARIS SEEDS. **Nemtseva, L. S.; Romanov, V. P. (Inst. of General Genetics, Moscow). Genetika; 7: No. 9, 42-50(Sep 1971). (In Russian).**

The frequency of chromosome aberrations induced by x- and gamma irradiation in air-dry (water content about 7%) and dry (water content about 4%) seeds of Crepis capillaris was the highest in cells that were the first to enter mitosis and much lower in those that were the last to proceed to mitosis. This difference was the most conspicuous in the population of embryonic cells derived from one seed. The difference between cells derived from different seeds but not different in the time of the onset of mitosis proved to be slight. As the result of treatment of super-dry seeds (water content about 1%) with sparsely ionizing radiation, the frequency of induced chromosome aberrations was the same in all the cells irrespective of the time of the mitosis onset. As a result of the treatment of dry (water content about 4%) seeds with fast neutrons, the frequency of chromosome aberrations was different in cells that proceeded to mitosis at different times, but the character of this dependence was not the same as in the case of sparsely ionizing irradiation of dry seeds. These arrangements were observed both in cells that were first and those that were last to proceed to mitosis, while the lowest frequency was observed in cells with the intermediate time of mitosis onset. (auth)

57969 RADIATION RESISTANCE IN PLANTS CULTIVATED AT HIGH ALTITUDES. **Nuzhdin, N. I.; Pastushenko-Strelets,**

N. A. (Inst. of Biological Physics, Moscow). Dokl. Akad. Nauk SSSR; 197: No. 4, 954-7(1 Apr 1971). (In Russian).

Barley seeds from plants grown in the regions near Moscow, Tallin, Tartu, and the Pamirs were irradiated with ^{137}Cs gamma radiation (10 Ci). Radiosensitivity of the seed could not be correlated with moisture content in the seed. However chromosomal damage was least in the case of the Pamir-grown seed, and greatest for the seed from the Tallin area, indicating that a distinct increase in radioresistance was inherent in barley seed grown under conditions of high altitudes. Cytological analysis was also conducted on barley seed that was obtained from plants grown in the absence of the uv portion of the spectrum. The results indicated that the frequency of chromosomal aberrations in such seed after γ irradiation was significantly higher than in irradiated controls (seed grown under light conditions normal to the western Pamirs). (K.S.W.)

57970 LIMITED CONTRIBUTION OF DNA REPAIR IN THE RECOVERY OF CHROMOSOMES FOLLOWING IONIZING RADIATION. Mikhel'son, V. M. (Inst. of Cytology, Leningrad). Tsitologiya; 13: No. 8, 932-45(Aug 1971). (In Russian).

According to the author's hypothesis, the metazoan chromosomes possess a lowered, if any, reparative capacity following treatment with ionizing radiation, since the latter extends its damaging effect to involve not only the chromosomal DNA, whose reparation is possible, but also some interreplicon links of different chemical nature, whose reparation is impossible or difficult. UV rays cause the damage of DNA only, therefore the injuries of that kind are reversible. Genetical structures in bacteria involve only one replicon, and thus the reparation of bacterial DNA is, at the same time, the recovery of the whole genetic apparatus of the cell. (auth)

57971 INDUCTION OF MUTATIONS IN BACTERIOPHAGE ΦX174 BY IONIZING RADIATION. Bleichrodt, J. F.; Berends-Van Abkoude, E. R.; Verheij, W. S. D. (TNO, Rijswijk, Netherlands). Kon. Ned. Akad. Wetensch., Proc., Ser. C; 74: 172-82 (1971).

Irradiation of suspensions of the amber mutants am9 and am14 of bacteriophage ΦX174 in nutrient broth or thiourea solutions by X- or γ-rays induces virus particles able to propagate on a suppressorless host. The efficiency of induction of revertants amounts to about 6×10^{-7} per lethal hit, both for irradiations in an oxygen and in a nitrogen atmosphere. For unknown reasons the induction under nitrogen increases sometimes with radiation dose. (auth)

57972 CHROMOSOME ABERRATIONS IN PERSONS EXPOSED CHRONICALLY TO IONIZING RADIATIONS. Deknudt, Gh.; Leonard, A.; Leonard, E. D. (CEN–SCK, Mol, Belgium). Genen Phaenen; 14: No. 2, 46(Apr 1971).

Studies were made on radiotherapy physicians occupationally exposed for a period of 3 to 30 years. Relationships between levels of chromosome aberrations, duration of exposure, and dose rates were observed. It is pointed out that interpretation of results is very difficult due to low dose rates, dose fractionation, different sources of radiation, and other factors. (H.L.W.)

57973 IN VITRO CHROMOSOMAL RADIOSENSITIVITY IN FANCONI'S ANEMIA. Higurashi, Makoto; Conen, Patrick E. (Univ. of Toronto). Blood; 38: No. 3, 336-42(Sep 1971).

Peripheral blood samples and skin fibroblast cultures from five children with Fanconi's anemia and four normal children were irradiated with 10 and 100 rads. Nonirradiated duplicate cultures were used as controls. Blood cultures were harvested after 52 and 72 hr of incubation and fibroblast cultures were harvested 24 hr after irradiation. The frequency of chromosomal breakage caused by irradiation was calculated by subtracting figures for nonirradiated samples from those for irradiated samples. After irradiation, the number of breaks/cell/rad in samples from Fanconi's anemia was approximately fourfold greater in lymphocytes and twofold greater in fibroblasts than in the controls. The number of dicentrics and rings per cell in cultured lymphocytes after 100 rads was significantly greater in the Fanconi's anemia samples than controls. Therefore, in vitro, chromosomes of cells from children with Fanconi's anemia were significantly more radiosensitive than those of controls ($p < 0.01$). (auth)

57974 MODIFICATION OF X-RAY RADIATION EFFECTS BY MEANS OF CHEMICAL SUBSTANCES. Langer, I. Genet. Slechteni; 42: No. 5, 17-22(1969). (In Czech).

The influence of cystein, urea and thiourea on the radio-sensitivity and mutability of spring barley, variety "Valtický", was studied. The seeds were steeped in a solution of the mentioned substances and then radiated with x-rays in doses of 100 R, 2500 R and 4000 R. The greatest protective effect in the M_1 generation was provided by urea, especially at higher doses of radiation. The sterility of the ears in the M_1 generation after the application of the protective substances in combination with lower radiation doses was greater than in control specimens subjected to radiation without protective substances. In combination with higher doses of radiation the sterility of the ears of the M_1 generation was the same as that of the control specimen. All the substances used lowered the frequency of chlorophyl mutation in the M_2 generation per 100 ears of M_1 and the frequency of chlorophyl mutation per 100 plants of M_2. (auth)

57975 CYTOGENETICS OF ZESTE EXPRESSION IN DROSOPHILA MELANOGASTER. Gelbart, William Martin. Madison, Wis.; Univ. of Wisconsin (1971). 110p. University Microfilms Order No. 71-16,868.

Thesis.

Rearrangements were employed to investigate the nature of the zeste-white relationship. X-ray induced dominant suppressors of zeste were recovered from three sorts of treated chromosomes: structurally normal z w^+ chromosomes, chromosomes deficient for zeste which were genetically Df(1) z w^+, and chromosomes duplicate in tandem for all or a portion of w^+ and which were designated z w^+ w^+. Genetical and cytological analysis of each of the 57 recovered suppressor strains was performed to localize the site of the suppressor mutation. As had previously been demonstrated by Gans, the only X chromosome loci implicated in the control of zeste expression are zeste and white. In addition, several dominant autosomal suppressors of zeste were isolated. At least three separate autosomal loci function in the promotion of the zeste phenotype. All w^+ alleles contained in tandem duplications and triplications of this locus are competent in promoting zeste expression. In contrast, insertional duplications of w^+ that do not include the z locus within the duplicated segment are incapable of promoting zeste coloration. Moreover, these insertions actually inhibit the zeste-expressing activity of functional w^+ alleles in the same nucleus. These differential responses of w^+ in promoting zeste expression, which depend upon the chromosomal location of w^+, can be termed an S-type position effect on w^+. A model describing these data as reflections of transcriptional control of the z-w system is detailed. In essence, the model suggests that in nuclei in which these genes are to function, the zeste, white, and autosomal Suppressor of zeste (Su(A)z) loci are brought into close physical proximity by a process akin to ectopic pairing. Polarized transcription from white, through Su(A)z and finally through zeste then occurs. This model is consistent with several peculiarities associated with the white locus and is applicable to other S-type position effect systems. The implications of this model for chromosomal regulation are discussed. As a secondary study, a fine structure analysis of zeste was undertaken. Among a small sample of spontaneous and EMS induced zeste mutants, three types of z allele were found. Heterozygotes for z^1 and each of these alleles are mutant. Homozygotes (females) for the first group (two alleles) have yellow eyes, while homozygotes for the second class (six mutants) are wild-type in eye color, and homozygotes for the third group (one mutant) have mottled brown eyes. Hemizygotes (males) for each of these alleles are wild-type. Among this small sample of z mutations, no intragenic complementation was noted. Attempts to spatially separate the one allele in the third group (z^{p69a}, peppered-69a) from seven other z mutants were unsuccessful. The maximum distance between z^{p69a} and any of these other alleles is 0.01 map units. (Diss. Abstr.)

57976 GENETIC CONTROL OF MUTATION INDUCTION IN SACCHAROMYCES CEREVISIAE. Lemontt, Jeffrey Fielding. Berkeley, Calif.; Univ. of California (1970). 136p. University Microfilms Order No. 71-20,843.

Thesis.

Twenty mutants of Saccharomyces cerevisiae were selected for reduced ultraviolet light (UV)-mutability as measured by locus reversion of the highly UV-revertible ochre-suppressible arg4-17 allele. These mutants represent only three unlinked recessive loci denoted by rev1, rev2, and rev3. The rev2 locus is on chromosome XII at a distance of 4.0 centimorgans distal to asp5. Neither rev1 nor rev3 is centromere-linked. Strains carrying rev1-1, rev2-1 and rev3-1 are moderately UV-sensitive with Dose Reduction Factors (DRF) of 3.7, 4.3, and 8.5 in the respective haploids and 2 in the three homozygous rev diploids compared to wild-type; rev1-1, rev2-1 and rev3-1 also confer X-ray sensitivity (DRF's of 2.4, 1.5, and 1.8 at 10% survival in respective homozygous rev diploids) and ethylmethanesulfonate (EMS)-sensitivity (DRF's at 1% survival of 1.1, 2.7, and 2.7 in respective rev haploids). Mutation induction controlled by a small number of genes is thought to be related to the repair of lethal DNA damage. UV-induced locus reversion of arg4-17 is reduced from the wild-type level about 35-fold at 265 erg/mm^2 in rev1-1 and rev3-1 strains, while in rev2-1 strains it is only reduced about 3.5-fold. At the same dose in the same strains, UV-induced locus reversion of the ochre-suppresible lys1-1 allele is also severely reduced in

XUM

the rev1-1 and rev3-1 strains (about 10 times), but to a lesser degree in the rev2-1 strain (two-fold). UV-induced reversion of arg4-6 is also reduced by rev1-1 and rev3-1 (about 5 times), but doubled by rev2-1. At lower UV doses rev2-1 exerts no effect. The average frequency of UV-induced forward mutation to ade1 or ade2 in all rev strains is reduced almost four-fold, while the frequencies of mutation induced by EMS are between two and three times greater in rev strains than in wild-type. UV-induction of respiratory deficiency in rev3-1 strains was between three and seven times the frequencies observed in wild-type strains, in rev2-1 strains it was reduced, and in rev1-1 strains it was unaffected. The rev1 and rev3 genes are thought to have a nonspecific action in reducing UV-mutation, while rev2 may be specific for reversion of nonsense alleles. Strains carrying two or more UV-sensitive genes were constructed. The UV-survival and UV-reversion phenotypes of multiple rev haploid strains indicate that REV genes do not act in a single linear pathway. The phenotypes of double mutants of rev and uvs9 suggest that REV pathways are not blocked by uvs9, but rather act on intermediates in DNA repair, one of which is produced earlier by the UVS9 pathway. The results of this study are consistent with a model already proposed for UV-mutagenesis in E. coli. The similarities and differences of rev mutants in yeast to exr and rec mutants in bacteria are discussed. (Diss. Abstr.)

57977 SPONTANEOUS SOMATIC RECOMBINATIONS IN A NICOTIANA XANTHI n.c. MUTANT AND THEIR INDUCTION BY GAMMA RADIATION: PRELIMINARY GENETIC STUDIES. Dulieu, Hubert; de Boelpaepe, Robert; Deshayes, Alain (Institut National de Recherches Agronomiques, Dijon, France). Compt. Rend., Ser. D; 272: No. 26, 3287-90(28 Jun 1971). (In French).

A chlorophyll mutation a_1 of intermediate dominance established reciprocal and non reciprocal variations in leaves. Their spontaneous frequency is small, but very much enhanced by gamma radiation. The descendants of these variants indicate that in the absence of reciprocity, the heterozygote sites are subject to conversions. (France)

Health Physics and Safety

57978 MEDICAL SURVEILLANCE OF WORKERS IN THE STORAGE CENTER FOR RADIOACTIVE WASTE. Bessuges (CEA, La Hague, France. J. Belge Radiol.; 54: No. 1, 101-9 (Jan-Feb 1971). (In French).

Medical problems of workers are discussed, especially for the nuclear center Hague. The center reprocesses irradiated fuel elements from French power reactors. Final deposition of waste products is discussed. Neither excessive irradiation nor internal contamination was observed. The following medical problems were encountered: feelings of claustrophobia and confinement because the worker does not see daylight; respiratory difficulties; irritation of nose, trachea, and sinuses, and conjunctiva because of dry air; excessive heat; disturbances of vision because of insufficient lighting in glove boxes; disturbances of the corporeal image during handling of remote manipulators; difficulties of movement, respiration, and heat exchange due to masks and protective clothing. (H.B.G.)

Radioactive Contamination and Decontamination

57979 (EUR-4667) RADIOACTIVE CONTAMINATION OF FOODSTUFFS IN COUNTRIES OF THE COMMUNITY IN 1969. (European Communities, Luxembourg. Commission). Jul 1971. 66p. (In several languages). Dep. NTIS (U. S. Sales Only). EUR DM 7,30.

Data are presented on the radioactive contamination of foodstuffs in the EURATOM countries in 1969. The data relate to the radionuclides ^{90}Sr and ^{137}Cs. An estimate is given of the ^{90}Sr intake. For 1969 this intake averaged 3,865 pCi of strontium-90, which corresponds to 14.4 pCi/gCa in the diet. (auth)

57980 (HASL-245) FALLOUT PROGRAM QUARTERLY SUMMARY REPORT, JUNE 1, 1971-SEPTEMBER 1, 1971. Hardy, Edward P. Jr. (New York Operations Office (AEC), N. Y. Health and Safety Lab.), 1 Oct 1971. 254p. Dep. NTIS.

Current data are presented from the HASL Fallout Program, the National Radiation Laboratory in New Zealand, and Radiological Physics Division at Argonne National Laboratory, and the EURATOM Joint Nuclear Research Centre at Ispra, Italy. The initial section consists of data summaries and notes covering the following topics: ^{90}Sr fallout and precipitation by ten degree latitude bands, the stratospheric inventory of ^{238}Pu, and stratospheric inventories of fission produces. Subsequent sections include tabulations of radionuclide levels in surface air, stratospheric air, fallout, milk, and tap water. (53 references) (auth)

57981 (HASL-245(App.)) APPENDIX TO FALLOUT PROGRAM QUARTERLY SUMMARY REPORT, JUNE 1, 1971-SEPTEMBER 1, 1971. (New York Operations Office (AEC), N. Y. Health and Safety Lab.). 1 Oct 1971. 429p. Dep. NTIS.

Data are tabulated from fallout monitoring programs carried out from June through September 1971. Results are included from: measurements of ^{89}Sr and ^{90}Sr deposition at various world land sites and Atlantic Ocean weather stations; the content of ^{90}Sr in New York City milk; the content of ^{137}Cs and ^{90}Sr in New York City drinking water; and the content of various radioisotopes in samples of surface atmosphere obtained in North, South, and Central America. (C.H.)

57982 REMOVAL OF ^{60}Co CONTAMINATION FROM THE SKIN. Vorob'ev, A. M. Gig. Sanit.; No. 6, 106-8(Jun 1971). (In Russian).

A method was sought for the decontamination of ^{60}Co from the skin. Cobalt-60 in the form of a dissolved salt was applied to the palm of the hand. The agents were: an economy soap as a control, EDTA, in the form of the sodium salt Trilon B, a mixture of x-aminoacetic acids (Polycomplexon), and the sodium salt of diethylenetriaminepentaacetic acid (DTPA). The decontamination ability of a given agent depended on the physico-chemical state of the Co compound. Simple contact contamination was most easily cleaned off. HCl solutions of Co were more complex. A second contamination of the skin immediately after decontamination brought on the worst situation, because the protective skin oils had been removed. (K.S.W.)

57983 DATA. SECTION I. MILK AND FOOD. Radiol. Health Data; 12: No. 8, 411-20(Aug 1971).

Data are presented on the content of ^{140}Ba, ^{137}Cs, ^{131}I, ^{89}Sr, and ^{90}Sr in milk samples collected from various locations throughout North, South, and Central America during April 1971. (C.H.)

57984 DATA. SECTION III. AIR AND DEPOSITION. Radiol. Health Data; 12: No. 8, 422-6(Aug 1971).

Data are presented on the gross β radioactivity in samples of surface atmosphere and precipitation collected from various locations throughout North, South, and Central America during April 1971. (C.H.)

57985 DATA. SECTION IV. OTHER DATA. Radiol. Health Data; 12: No. 8, 427-38(Aug 1971).

Data are presented on the levels of radioactivity in the environment of the environs of Oak Ridge, Tennessee and Aiken, South Carolina during the last half of 1969. (C.H.)

57986 CONTAMINATION OF SOILS AND PLANTS WITH ^{90}Sr AS CONSEQUENCE OF NUCLEAR WEAPONS TESTS DURING THE PERIOD 1960 THROUGH 1963. Fiedler, H. J.; Reissig, H. (Technische Univ., Dresden). Biol. Rundsch.; 3: No. 4, 149-68(1965). (In German).

For the period 1960 to 1963, ^{90}Sr contamination of soil and agriculturally important plants was studied for the DDR and compared with international data. An increase in ^{90}Sr content of soil showed a correlation with fallout from nuclear weapons tests. Differences between various regions resulted from variation in rainfall. ^{90}Sr contamination of plants increased from 1961 through 1963 in good agreement with international data. Plants such as potatoes and cabbage, which are not too sensitive to surface contamination, showed a lesser increase in radioactivity than grass and grain. (H.B.G.)

57987 TRACE ELEMENT CONTENTS AND NATURAL RADIOACTIVITY OF FOODS IN SOME DISTRICTS OF KIEV REGION. Barannik, P. I.; Mikhalyuk, I. A.; Motuzkov, I. N.; Yatsula, G. S. (Kiev Medical Inst.). Vop. Pitan.; 29: No. 1, 79-81(1970). (In Russian).

Mean values with SEM are tabulated for Ni, V, Ba, Cr and Mn contents and natural radioactivity of samples of wheat, millet, maize, sunflower seeds, beans, potato, red beet, cabbage, onion, garlic, radish, apple, pear and plum from districts free from endemic goitre (4-18 samples of each item) and districts affected by endemic goitre (4-29 samples). Highest contents were: Ni, cereals and beans; V, beans, vegetables; Ba, cereals, some vegetables; Cr, beans, garlic, onion; Mn, beans, cereals, some vegetables. In general, contents of Ni, V, Ba and Cr were higher in the districts affected by goitre. Radioactivity was mostly due to ^{40}K naturally present; it was highest in beans and sunflower seeds. (EURATOM)

57988 RADIOACTIVITY OF FOODSTUFFS IN 1970. Miserez, A. (Service Federal de l'Hygiene Publique, Bern). Mitt. Geb. Lebensmittelunters. Hyg.; 61: No. 2, 165-92(1971). (In French).

The present level of radioactivity in the food supply in Switzerland does not present any danger to the human population. The average content of ^{90}Sr in milk is 12 pCi/liter, the same as it was in 1969. The uptake of ^{90}Sr through foods amounts to approximately 18 pCi/person/day; whereas it was as high as 100 pCi in 1964. The Chinese nuclear explosion in September 1969 and the French nuclear tests in 1970 had no significant effect on the radioactivity of foods produced in Switzerland. (H.B.G.)

57989 RADIOACTIVITY OF FOODSTUFFS IN 1969. Miserez, A. (Service Federal de l'Hygiene Publique, Bern). Mitt. Geb. Lebensmittelunters. Hyg.; 61: No. 1, 89-116(1970). (In French).

Radioactive fallout from the Chinese explosions in December 1968 and September 1969 augmented the radioactivity of milk in Switzerland during the vegetative period of grass, especially through an increase in ^{90}Sr. The degree of contamination was relatively slight and presented no danger to the population. Although, after the September explosion, the presence of ^{131}I could be demonstrated in the thyroid glands of dairy cattle, its concentration in milk was too low to be detectable. Altogether, the ^{90}Sr content, which is the main contaminant of foods, decreased somewhat in comparison with 1968. From the average ^{90}Sr content of plain milk, amounting to 12 pCi/liter, the amount of ^{90}Sr taken up by man was 18 pCi/person/day in comparison to 22 pCi in 1968. (H.B.G.)

57990 DATA. SECTION I. MILK AND FOOD. Radiol. Health Data Rep.; 12: No. 7, 371-80(Jul 1971).

Data are presented on the content of ^{140}Ba, ^{137}Cs, ^{131}I, ^{89}Sr, and ^{90}Sr in samples of milk collected from various locations throughout North, Central, and South America during March 1971. (C.H.)

57991 DATA. SECTION II. WATER. Radiol. Health Data Rep.; 12: No. 7, 381-7(Jul 1971).

Data are presented on the gross α and β radioactivity and content of ^{226}Ra, ^{90}Sr, and tritium in samples of drinking water and tritium in samples of surface waters collected throughout the USA during 1970. (C.H.)

57992 DATA. SECTION III. AIR AND DEPOSITION. Radiol. Health Data Rep.; 12: No. 7, 388-92(Jul 1971).

Data are presented on the gross β activity in samples of surface atmosphere and precipitation collected throughout North, Central, and South America during March 1971. (C.H.)

57993 DATA. SECTION IV. OTHER DATA. Radiol. Health Data Rep.; 12: No. 7, 393-404(Jul 1971).

Data are presented on levels of radioactivity in the environment in the vicinity of the Savannah River Plant, Aiken, S. C., during 1970. A list of underground nuclear explosions reported during June 1970 is included. The venting of Baneberry low yield underground nuclear explosion of December 18, 1970, resulted in the release of less than one milliroentgen per hour at offsite locations in the vicinity of the Nevada Test Site. Monitoring activities are described. The data showed that the levels of radioactivity released presented no health hazards to persons living downwind. The exposure of onsite personnel did not exceed the occupational guides set by the Federal Radiation Council. (C.H.)

57994 EXPOSURE OF HUMAN BEINGS TO NATURAL AND ARTIFICIAL SOURCES OF IONIZING RADIATIONS. Rodier, J.; Vernhes, C.; Estournel, R. Maroc Med.; 49: 75-91(Feb 1969). (In French).

Surveyed are both natural and artificial sources of ionizing radiation in relation to man. Included are cosmic radiation of galactic origin, particle radiation from the sun, and radiation within the Van Allen belts. Natural radioactive isotopes, such as ^{3}H, ^{14}C, ^{40}K, ^{87}Rb, ^{232}Th, and ^{238}U, and internal natural sources of radioactivity, such as ^{3}H, ^{14}C, and ^{40}K are discussed. Content of radioactivity is listed for various bodies of water and for different types of foodstuffs. With respect to artificial radiation sources, the following topics are discussed: medical equipment, peaceful uses of nuclear energy, and fallout from test explosions. Results of the survey are compiled in 16 tables. As far as natural radiation sources are concerned, solar radiation represents 50% of total human exposure; then follows cosmic radiation with 30%, and ^{226}Ra deposition in the bone. During solar flares, doses between 30 and 60 rem were measured within 2 to 3 hours at 50 km altitude over France. (H.B.G.)

Dosimetry and Monitoring

57995 (CONF-711013–1) CHEST CLEARANCE OF INHALED ^{60}Co OXIDE. Brown, P. E.; Gupton, E. D. (Oak Ridge National Lab., Tenn.). [1971]. 9p. Dep. NTIS.

From 17. annual bioassay and analytical chemistry meeting; Boulder, Colo. (13 Oct 1971).

Chest counting data have been collected for about four years for a human case which involved inhalation of ^{60}Co-oxide. The measured chest burden, which decreases with successively increasing half-times (about 10 months at early times to about 60 months after three years), may be calculated almost precisely with an expression related directly to the model of the Task Group on Lung Dynamics. Only the delayed transfer half-time and the long-term fraction retained in pulmonary lymph nodes of the Class Y model need be adjusted to fit this case. With the exception of the long-term fraction in the lymph nodes, only one rate of elimination seems to be present, 225 days, throughout the period of observation. (auth)

57996 (DPSPU–71–30–16) EFFECT OF THE SAVANNAH RIVER PLANT ON ENVIRONMENTAL RADIOACTIVITY. Semiannual Report, January–June 1971. (Du Pont de Nemours (E. I.) and Co., Aiken, S. C. Savannah River Plant). Sep 1971. Contract AT(07-2)-1. 13p. Dep. NTIS.

The results of the environmental monitoring program for the atmosphere, vegetation, milk, and water in the vicinity of Aiken, S. C., for the period January 1 through June 30, 1971, are presented. The quantity of radioactive waste released by the Savannah River Plant to its environs was, for the most part, too small to be distinguished from natural background radiation or was obscured by fallout from offsite sources. Beta activity in air, which showed no relationship with plant operations and was due to global fallout, was slightly higher than that observed for the same period of 1970 and there was a two-fold increase over the previous six-month period. Radioactive materials in fish flesh continued to be far below levels considered significant from a health standpoint. The average concentration of any radionuclide in Savannah River water at Highway 301 did not exceed 0.3% of the concentration guide. (auth)

57997 (LBL–314) IN VIVO RADIOBIOLOGICAL STUDIES OF 910 MeV HELIUM ION BEAM. Chong, Claude Y. L. (California Univ., Berkeley. Lawrence Berkeley Lab.). Aug 1971. Contract W-7405-eng-48. 97p. Dep. NTIS.

Thesis.

Both the modified Bragg peak and the plateau portion of the 910 MeV helium ion beam from the Berkeley 184'' synchrocyclotron (henceforth abbreviated as "peak α" and "plateau α" respectively) were compared to cobalt-60 gamma rays (^{60}Co γ) by using 3 modes of total body exposure to evaluate 3 parameters in each of 4 in vivo systems in 13 to 14 week old female LAF$_1$ mice. The 3 modes of exposure were single dose in air, split dose in air, and single dose under hypoxia, and the 3 parameters evaluated included relative biological effectiveness (RBE) in air, recovery pattern in air expressed as percentage of recovery of the first dose (%R), and oxygen enhancement ratio (OER). The 4 test systems consisted of 6-day animal survival, 30-day animal survival, survival of microscopic intestinal colonies, and survival of macroscopic endogenous spleen colony forming units (CFU). Because the survival curves in each set were not parallel, the doses to achieve iso-effect were compared at several survival levels in order to elicit a more composite picture. For lethality studies, besides the more reliable median lethal dose (LD$_{50}$) conventionally used, the 90% and 10% lethal doses (LD$_{90}$ and LD$_{10}$ respectively) were also evaluated. For intestinal colonies, in addition to the slope (inverse of D$_0$) and the "extrapolation number" at zero dose (n), the doses resulting in 100 colonies and 10 colonies were computed. For spleen colonies, similar data were obtained except that the 2 levels of survival selected were 10 colonies and 1 colony. The RBE of peak α was significantly greater than unity for all end points of the 4 systems under consideration. It ranged from 1.17 to 1.39, being greater than 1.25 in most instances. On the other hand, plateau-α RBE was not significantly different from unity, with a mean effectiveness of 1.12. Recovery at 48 hours after exposure was in general greater in the intestines than in hemopoietic tissues. For gut death, it amounted to 51.4 to 67.4%, depending on the survival level and was almost identical for all 3 types of radiation. For marrow death, peak-α irradiated mice showed significantly less capacity for recuperation than those exposed to plateau α or ^{60}Co

XUM

γ, especially at LD$_{90}$ level (16.7 vs 33.6 and 47.5%). For intestinal colonies, again, the 3 types of radiation were comparable, and remarkable recovery of 80.0 to 114.6% was observed. Moreover, all 3 recovery regression lines were less steep than their single dose counterparts, the change in D$_0$ ranging from 50.9 to 66.1%. For spleen colonies, the change in D$_0$ was least with peak α (15.2%) than with plateau α (44.8%) or ^{60}Co γ (50.9%). At 10 colony level, all 3 radiations resulted in similar recovery (45.6 to 51.6%). However, at 1 colony level, again peak α produced more irreparable damage as evidenced by only 49.6% recovery compared to 64.0 to 65.8% after ^{60}Co γ and plateau α exposure. The oxygen effect varied according to the end point chosen, even for the same type of radiation. Nonetheless, a comparison of corresponding end points showed that peak α had a lower OER (2.02 to 2.22) than ^{60}Co γ (2.30 to 2.57) except for intestinal colony survival, and that although plateau α appeared to have slightly less oxygen effect than ^{60}Co γ, the difference was of doubtful statistical importance. Good correlation was noted between gut death and crypt cell survival and between marrow death and spleen CFU survival. (auth)

57999 (NP-18944) DOSIMETRY OF IONIZING RADIATION ON DROSOPHILA MELANOGASTER. EFFECT ON THE SPONTANEOUS RATE OF DISJUNCTION AND LOSS OF CHROMOSOME X. de los Angeles Galindo Becerra, Ma. (Universidad Nacional Autonoma de Mexico, Mexico City. Facultad de Ciencias). 1971. 59p. (In Spanish). Dep. NTIS (U. S. Sales Only).

Thesis.

The use of Drosophila melanogaster as a biological dosimeter was investigated by testing two of the effects found in Drosophila: loss of chromosome X and disjunction of the heterochromosomes. The results showed that there is a relation, which is adjustable to a linear function, between the dose and the frequency of the chromosome X loss. No relation was observed for disjunction. It was concluded that the chromosome X loss could be adapted for use as a biological dosimeter. (J.S.R.)

58000 (RD/B/R-1934) BIOLOGICAL ASPECTS OF SKIN IRRADIATION. PART III. NEW EPIDERMAL THICKNESS MEASUREMENTS AND THEIR IMPORTANCE. Whitton, J. T. (Central Electricity Generating Board, Berkeley (England). Berkeley Nuclear Labs.). Apr 1971. 54p. Dep. NTIS (U. S. Sales Only).

A new method for measuring epidermal thickness that is applicable in radiation dosimetry is described. The procedure has several advantages over conventional techniques since elasticity is accounted for. Quick measurements were made on 214 samples taken from 188 persons by means of a biopsy punch. Epidermal thickness was correlated with sex, age, and body site. The complete detailed results are given and discussed together with simplified adaptions for use in radiation protection. (UK)

58001 (UCRL-73388) PLEA FOR CONSISTENT LUNG BURDEN CRITERIA FOR INSOLUBLE ALPHA EMITTING ISOTOPES. Myers, David S. (California Univ., Livermore. Lawrence Radiation Lab.). [1969]. 13p. (CONF-710919-1). Dep. NTIS.

From eleventh symposium on the biological implications of the transuranium elements; Richland, Wash. (27 Sep 1971).

The maximum permissible annual dose to human lungs as defined by existing radiation standards is 15 rem/year. In the case of lung doses resulting from α-emitting isotopes, the assumption is made that the α energy is deposited uniformly in the lung tissue and that the mass of the lungs is 1000 grams. The amount of α activity in the lungs which will produce a dose rate of 15 rem/year is on the order of 10 to 20 nCi depending upon the effective half-life of the α-emitting isotope. In 1966 a revised lung model was promulgated by the ICRP Task Group on Lung Dynamics that more clearly defines the deposition compartments in the respiratory system, and considers the effect of particle size on deposition, the chemical form of the inhaled material, and the specific clearance pathways from the various deposition compartments. It is of special interest in the case of insoluble isotopes that the revised lung model stipulates that 15% of the activity deposited in the pulmonary region is eliminated to the pulmonary lymph nodes and that 90% of this activity is retained in these lymph nodes permanently. Based on this revised lung model, the dose received by the pulmonary lymph nodes is considerably greater than the dose received by the pulmonary region of the lungs for either acute or chronic inhalation of insoluble ^{239}Pu. Calculations were made of the integrated radiation dose to the lungs and the amount of activity remaining in the lungs 50 years following acute and chronic inhalation of ^{239}Pu. The parameters for each of the exposure categories and the corresponding computations are included. (C.H.)

58002 RADIATION UNITS AND THE MEASUREMENTS OF IONIZING RADIATION. Spiers, F. W. (Leeds Univ., Eng.). Phys. Educ.; 6: No. 5, 257-62(Sep 1971).

It is shown that a system of dosimetry, based on the concept of energy absorbed in the irradiated tissues, has evolved from earlier and more limited procedures. The absorbed dose unit, the rad, is satisfactory for the practical purposes of radiotherapy and radiation protection and is now in universal use. For a complete understanding of radiobiological effects, however, energy absorption must be considered at subcellular and molecular levels. Experimental and theoretical studies of the kind briefly described are now leading to greater precision in the concept of radiation dose and to deeper knowledge of radiation action. (UK)

58003 DOSE ESTIMATION IN TANGENTIAL RADIATION THERAPY. Takeshita, Kenji; Sunayashiki, Tadashi (Hiroshima Univ.). Nippon Igaku Hoshasen Gakkai Zasshi; 30: No. 9, 801-4 (Dec 1970). (In Japanese).

In tangential radiation therapy of the breast, dose distributions were obtained for one projection by calculating depth doses. The attenuation of ^{60}Co gamma rays in tissue was calculated using the linear absorption coefficient 0.055 cm^{-1} for the geometrical field. Contribution of secondary electrons absorbed at a point was limited to an area in a circle of which the radius was 0.5 cm on sagittal section. A rotation teletherapy unit was used with its fully opened field half shielded by lead. A film sandwiched between semi-cylindrical acrylite plates was tangentially exposed at the isocenter. Distributions obtained by these two methods were compared. The calculation technique is simple and reliable in estimating doses at any point in the breast during tangential and eccentric pendulum therapy. (auth)

58004 WHOLE-BODY ABSORBED DOSE FROM 44 keV AND 105 keV X RAYS AND ^{60}Co GAMMA RAYS. Kumamoto, Yoshikazu; Kato, Yoshio; Maruyama, Takashi; Shiragai, Akihiro; Yoshida, Yoshikazu (National Inst. of Radiological Sciences, Chiba, Japan). Nippon Igaku Hoshasen Gakkai Zasshi; 30: No. 2, 117-23(May 1970).

The absorbed dose in the head, arms, abdomen, legs, and whole body was obtained for a homogeneous phantom from 44 keV and 105 keV x rays and ^{60}Co γ rays by measuring the exposure distributions in water phantoms with an ionization chamber. The position of the phantom was in front of, to the side of, and at an angle of 45 degrees to the beam. The amount of absorbed dose in the whole body was 0.4 to 1.0 rad for 1 R of free air exposure. (auth)

58005 QUALITY FACTOR OF RADIATION. Zielczynski, M. (Inst. of Nuclear Research, Swierk, Poland). Nukleonika; 15: No. 11-12, 823-30(1970). (In Russian).

There are two definitions of the quality factor (QF): the first, in which QF is the expected relative biological efficiency of radiation for the general risk of body irradiation at low doses, and second, in which QF is a definite function of linear energy transfer (LET, L) of the particles ionizing the tissue. One can calculate, measure, and compare the quality factors of radiations according to the second definition with an accuracy limited by the diversity of meaning in formulation of the QF(L) function. It is suggested to take the QF−LET response of one of the known QF-detectors as a standard function. (auth)

58006 RADIATION SAFETY OF THE CREW OF SOYUZ-9. Vorob'ev, E. I.; Getselev, I. V.; Grigor'ev, Yu. G.; (and others). Kosm. Biol. Med.; 5: No. 4, 29-33(Jul-Aug 1971). (In Russian).

A careful analysis was made of the trajectory of the spaceship Soyuz-9 in order to evaluate the radiation hazards to be encountered. It was predicted that the combined galactic cosmic radiation and the radiation belts of the earth would not exceed an integral dose of 0.25 rad although part of the trajectory might be subject to 100 MeV protons, as a result of solar flares. Measurements of cosmic radiation were made in an artificial satellite, and from these and other data it was concluded that the integral cosmic radiation dose in the spaceship up to the completion of the flight would amount to 195 mrad (11 mrad per 24 hr), which did not represent a hazard to the cosmonauts. (K.S.W.)

58007 INDIVIDUAL RADIATION PLANNING AS PREREQUISITE FOR APPLICATION OF COMPLICATED TECHNIQUES IN MEGAVOLT THERAPY. Heilmann, H.-P. (Univ., Tuebingen, Ger.). Roentgenpraxis; 24: No. 7, 159-67(Jul 1971). (In German).

Since megavolt therapy permits high local radiation doses, exact individual planning becomes mandatory for optimal dose distribution in the tumor area. Descriptions are given for localization of the target area, radiometry methods, dose calculations, and control of equipment adjustment. The completed radiation plan, mostly obtained by computer, yields not only isodose curves but also important factors for pendulum irradiation, such as radius, depth of axis, width of aperture, angle for pendulum sectors, and exposure times. Several examples are given. (H.B.G.)

58008 COMPUTER PROGRAMS FOR IRRADIATION PLANNING IN HIGH-ENERGY THERAPY. Dobry, H.; Benedetti, G. R. (Siemens AG, Erlangen, Ger.). Electromedica; No. 3, 219-26(1970).

Data processing is becoming increasingly important in many branches of medicine. In radiotherapy the calculation of dose distribution is its most important task in the future. A general picture of the present state of development of dose computation by means of computer data processing and a detailed description of a program developed for betatron high energy and ^{60}Co γ units are presented. (auth)

58009 COMPUTER PROGRAM FOR DETERMINATION OF ISODOSE CURVES FOR ELECTRON ENERGIES FROM 5 TO 42 MeV. Benedetti, G. R.; Dobry, H.; Taumann, L. (Siemens AG, Erlangen, Ger.). Electromedica; No. 2, 57-60(1970).

The experimental determination of stationary field data and the resulting consequences for measurements of the radiation dose distribution from high-energy electrons used for therapy are discussed. A computer program is described that allows the calculation of stationary fields, multi-fields, and pendulum fields for electron energies of 5 to 42 MeV. (auth)

58010 DIRECT MEASUREMENT OF DOSE RATE IN THE BLADDER AND RECTUM USING THE GAMMAMETER. Glaser, F. H. (Martin-Luther Univ., Halle, Ger.). Electromedica; No. 1, 24-6(1969).

A radiation dose which exceeds the tolerance of the bladder and rectal mucous membrane during gynaecological contact curie therapy can lead to damage which will reduce the success of the treatment. Comparative evaluation of ^{60}Co applicator combinations in 600 female patients revealed that in over half of all cases the orientation resulted in over-exposure of between 50% and 90%. In order to incorporate a security factor a strict application time with regard to clinical requirement was established so that 5500 R to the bladder and rectum will not be exceeded. Even in the most unfavorable case, exposure to the mucous membrane will then not be greater than about 7000 R. The determination of the dose rate with a gamma meter provides a useful indication concerning the radiation exposure of bladder and rectum. The described method of direct measurement of the dose rate of the applicator in situ is regarded as the preferred method. (auth)

58011 EVALUATION OF TELEVISION CONTRIBUTION TO THE ANNUAL GENETICALLY SIGNIFICANT RADIATION DOSE OF THE POPULATION. Radiol. Health Data Rep.; 12: No. 7, 363-70(Jul 1971).

The X-radiation Ad Hoc Committee of the Electronic Industries Association used data from a U. S. Public Health Service survey of color television receivers in the Washington, D. C. area to estimate the annual genetically significant x radiation dose to the U. S. population from television usage. Using these data and various assumptions, the annual genetically significant dose was estimated by the committee to be 0.5 mrem. (auth)

58012 DIRECT METHOD OF MEASURING TOTAL RADIATION DOSE TO THE BRAIN USING THE FRICKE DOSIMETER. Werner, A.; Modan, B. (Tel Hashomer Government Hospital, Israel). pp 435-44 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Doses of radiation to the brain of children receiving x-ray therapy for tinea capitis were determined by the use of chemical dosimetry. The average dose absorbed by the brain of a 7-yr-old child was 99 ± 4 rads. This average dose measured with chemical dosimetry was compatible with the lower doses obtained with the ionization chamber method. An experimental model was devised to determine the effective photon energy of the radiation. On the basis of these results it is suggested that chemical dosimetry could have wider applicability in the measurement of doses absorbed by functionally homogeneous organs. (auth)

58013 USE OF CHROMOSOME ABERRATION FREQUENCIES FOR BIOLOGICAL DOSIMETRY IN MAN. Evans, H. J. (Western General Hospital, Edinburgh). pp 593-609 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The vast amount of work on chromosome aberrations induced by radiation exposure under defined biological and physical conditions, has shown that there exist strict relationships between aberration frequencies, radiation quality, and absorbed dose in a variety of cell systems. These relationships are such that in many irradiated plant and animal systems the frequency of induced chromosome aberrations was used to give reliable estimates of the radiation dose to which the system was exposed. A similar extrapolation from induced aberration frequency to absorbed dose can be made with human peripheral blood lymphocytes, if such cells are exposed and cultured in vitro under well defined

XUM

conditions. Moreover, since aberrations induced in lymphocytes following an in vivo exposure can be detected in the cells when subsequently cultured in vitro, the peripheral blood leucocyte system was utilized for biological dosimetry in cases where individuals were accidentally exposed to radiations. In the case of uniform whole-body exposure of an individual, and under defined conditions of in vitro culture, the system may be expected to fulfil most of the requirements for a sensitive and accurate biological measure of absorbed dose. In this context, biological variations between individuals may be of importance and the influence of such factors as age and genotype on the radiation response is considered. In cases of partial-body exposure, there are a variety of biological factors that may have a considerable influence on the yields of aberrations measured in cells removed from the body shortly after exposure. Factors that are important include: the proportions of lymphocytes located in or passing through the radiation field at the time of exposure; the distribution and mobility of lymphocytes between peripheral blood and the lymphoid systems; differences in the radiation response of lymphocytes of differing types; and differences in the capacities of irradiated and non-irradiated lymphocytes to undergo mitosis in culture. Recent evidence bearing on these problems is discussed. (auth)

58014 USE OF RADIATION-INDUCED CHROMOSOME ABERRATIONS IN HUMAN LYMPHOCYTES FOR DOSIMETRY. Dolphin, G. W.; Purrott, R. J. (United Kingdom Atomic Energy Authority, Harwell, Eng.). pp 611-22 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

During the past decade, techniques were developed for the analysis of radiation-induced chromosome aberrations in human lymphocytes. In the last few years there was an increasing awareness of the value of these techniques in dosimetry, where they were used to estimate doses in suspected or known cases of accidental over-exposure. Experience gained from these cases has shown that several factors have an important effect on the dose estimate. These factors are discussed in this paper. Published data relating dicentric aberration yield to in vitro irradiation dose show considerable variation from laboratory to laboratory. These data are reviewed and compared with similar values obtained at Harwell. Factors that affect the aberration yield include dose rate, type of radiation, culture time, and the ability of the cells to transform following irradiation. In order to obtain consistent calibration curves, standard conditions are suggested for irradiation of blood samples that closely resemble those for accidental in vivo irradiation. After in vivo irradiation, the measured dicentric yield is influenced by additional factors, particularly lymphocyte kinetics, and a short review of this subject is included. Some practical aspects are discussed including the dispatch and preparation of the blood sample taken after a radiation accident and the accuracy and sensitivity of this method of dosimetry. Future developments in chromosome dosimetry are considered and the need for automated recognition of aberrations is stressed. (auth)

58015 RELEVANCE OF CHROMOSOME ABERRATION YIELDS FOR BIOLOGICAL DOSIMETRY AFTER LOW-LEVEL OCCUPATIONAL IRRADIATION. Bauchinger, M.; Schmid, E.; Hug, O. (Institut fuer Biologie, Neuherberg, Ger. Univ., Munich). pp 623-32 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

The usefulness of chromosome analysis for biological dosimetry was tested in two groups of persons occupationally exposed to radiation: in nurses employed in gynaecological radiology, exposed especially when handling radium inserts; and in nuclear industry workers, all exposed to external gamma irradiation and some also to internal radiation after incorporation of various radionuclides. The total dose registered with personal dosimeters ranged in Group I from 0.1 to 91.7 rem accumulated over working periods of 0.1 to 13 yrs, and in Group II from 1.0 to 18.2 rem accumulated over 1 to 9 yrs. Compared with unexposed controls, both groups exhibit a significant increase of cells with chromosome aberrations as well as larger numbers of breaks per cell. Dicentrics and rings could be observed in some cells, providing good evidence for previous radiation exposure, since these types of aberrations are extremely rare events in unexposed individuals. No correlation between the aberration yields and the film badge values could be demonstrated in Group II. Also, in Group I the fluctuations from individual to individual were high. Nevertheless, a positive correlation to the dose was obtained. Even a sub-group of the nurses that had only been exposed to 20 rem showed significantly more aberrations than control persons. From the results obtained, type and frequency of chromosome aberrations may be considered an indicator of radiation exposure even at low doses. The reasons for lack of correspondence of chromosome aberration yields and the results of personal monitoring procedures are discussed in detail. (auth)

58016 USE OF CHROMOSOME ANALYSIS FOR BIOLOGICAL DOSIMETRY IN CONNECTION WITH AN ACCIDENT INVOLVING ^{226}Ra. Todorov, S.; Keslev, D.; Statelov, V.; Vasilev, G.; Ivanov, B. (Inst. of Engineering Physics, Moscow). pp 647-56 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In Russian).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

An incident with radium-226 directly involving two children aged twelve and thirteen is described. The physical and medical data obtained in this case are presented. A careful analysis of the numerical and structural chromosome damage suffered by the children was carried out by means of lymphocyte cultures. The dose received by the children was calculated on the basis of chromosome analysis. The observed chromosome injuries are compared with data from calibrated curves in the literature and with data obtained by the authors themselves through in vitro irradiation of lymphocyte cultures from human peripheral blood. (auth)

58017 APPLICATION OF THE PLASMA-QUENCHING EFFECT FOR EMERGENCY AND ACCIDENT RADIATION MONITORING. Mahmoud, K. A. (Atomic Energy Establishment, Cairo); Kotb, M. A. M. pp 657-63 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Due to the difficulty of devising a physical monitoring system that simulates in all respects biological organisms, it would be highly desirable to use biological monitoring methods. Changes in blood elements and, particularly, in plasma were selected as an appropriate biological indicator for personnel monitoring. Groups of rats were given whole-body doses between 25 and 250 rads from a ^{60}Co teletherapy unit. Blood samples were taken immediately after irradiation, and after periods of one-half day to sixteen days after exposure. The changes in the quenching effect of plasma as a result of these whole-body exposures were measured by means of liquid scintillation counting of tritiated water mixed with this plasma. The results indicate reproducible quenching effects that depend on the radiation dose for plasma samples taken just after irradiation. For plasma samples taken between one-half day and sixteen days after irradiation, the results indicate a recovery effect. The application of the method in emergency and accident monitoring is suggested. (auth)

58018 BIOLOGICAL DOSIMETRY METHODS EMPLOYED AT THE BORIS KIDRIC INSTITUTE OF NUCLEAR SCIENCES. Aleksic, B.; Veljkovic, D.; Djordjevic, O.; Djukic, Z. (Boris Kidric Inst. of Nuclear Science, Belgrade). pp 687-95 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971). (In French).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

In addition to the more usual methods, the following methods are used at the Boris Kidrič Institute of Nuclear Sciences in the medical supervision of occupationally exposed staff: analysis of binucleated lymphocytes and chromosome aberrations; physical examination (for example, determination of the pain sensitivity threshold, adaptation to pain, discrimination of sensitivity); and capillaroscopy. These methods are described briefly and their practical application discussed. (auth)

58019 NEUTRON DOSE DETERMINATION WITH ACTIVATION AND BIOLOGICAL DETECTORS IN THE BORIS KIDRIC INSTITUTE. Trajkovic, M.; Miric, Ivanka; Ubovic, Z. (Boris Kidric Inst. of Nuclear Sciences, Belgrade). pp 697-703 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

A description of the dosimetric systems used in the Boris Kidrič Institute for the determination of neutron doses under accident conditions is given. The accident dosimeters consist of the following activation detectors: gold, copper, indium, sulphur, and magnesium. In addition, the sulphur in hair, and the blood sodium are used for evaluating the neutron dose values and for the determination of the distribution of the neutron doses during irradiation. For the evaluation of the neutron spectra the spectra index method was used. The dose values were determined for different spectra at the RA reactor at Vinča. The activation of the sulphur in hair, and the blood sodium, are correlated with the values obtained. The application of these physical and biological dosimeters and the expected precisions are discussed. (auth)

58020 COMPUTER PROGRAMS FOR IRRADIATION PLANNING IN HIGH-ENERGY THERAPY. Dobry, H.; Benedetti, G. R. (Siemens AG, Erlangen, Ger.). Electromedica; No. 5, 291-4 (1970).

Computer programs are presented for use in calculations of doses of high-energy γ and x radiation for therapy of neoplasms in inhomogeneous tissues. The programs allow calculations of the dose distribution as a function of wedge filter angle, filter material, and source-filter distance. (C.H.)

58021 COMPUTER PROGRAMS FOR IRRADIATION PLANNING IN HIGH-ENERGY THERAPY. Dobry, H.; Benedetti, G. R. (Siemens AG, Erlangen, Ger.). Electromedica; No. 4, 264-70 (1970).

Computer programs are presented for use in calculations of the therapeutic dose of high-energy γ and x radiations. The programs are written in FORTRAN IV, developed on the Siemens system 4004 and translated to the Siemens system 305, but they can be translated to other types of computer. (C.H.)

58022 X-RAY DOSE TO THE PATIENT IN MAXILLODENTAL TOMOGRAPHY. Sonnabend, E.; Polensky, F. (Georg-August Univ., Goettingen, Ger.). Electromedica; No. 3, 92-3(1971).

During the course of x ray tomography of the jaws and skull of 120 patients the dose was measured in the area of the head and gonads by means of ionization chambers and film dosimeters. Both skin dose and the gonadal dose were found to be greatly reduced as compared with normal 11-film fill-denture radiography. Moreover, the dose received by the patient during individual tomograms of the temporomandibular joint was ascertained and compared with the dose to the patient who was subjected to other methods of temporomandibular joint radiography (the functional radiograph). It was found that tomography lessens the dose to the patient and yields better diagnostic information. (auth)

58023 COMPARISON OF CALCULATED AND EXPERIMENTAL DOSE FIELDS OF A PROTON BEAM. Salamov, R. F.; Astrakhan, B. V.; Bal'ter, S. A.; Vainberg, M. Sh. (Inst. of Experimental and Chemical Oncology, Moscow). Med. Radiol.; 16: No. 9, 34-7(Sep 1971). (In Russian).

Data are presented on the experimental irradiation of human autopsy preparations of the neck and hip. The results of experiments were compared with data of calculations conducted with due consideration of the heterogeneity of the irradiated body and curvature of its surface. A good coincidence of calculated and experimental data was noted. (auth)

58024 (CONF-711104-1) PROPER USE OF INFORMATION ON ORGAN AND BODY BURDENS OF RADIOACTIVE MATERIAL. Morgan, Karl Z. (Oak Ridge National Lab., Tenn.). [1970]. 22p. (SM-150/50). Dep. NTIS.

From Symposium on the assessment of radioactive organ and body burdens; Stockholm, Sweden (22 Nov 1971).

Applications of data on the uptake and retention of various radioisotopes by human body organs and tissues in establishing maximum permissible values for internal radiation doses are discussed. Criteria used in the development of radiation protection standards by the International Commission on Radiological Protection (ICRP) since 1934 are reviewed. It is postulated that changes in values of maximum permissible concentrations of a number of radioisotopes will be incorporated in the 1973 edition of the ICRP Internal Dose Handbook on the basis of new uptake and retention data. (C.H.)

58025 (ORNL-tr-2490) EXPOSURE TO RADIATION IN ORBITAL FLIGHTS. Swart, Hans. Translated by R. Gregg Mansfield (Oak Ridge National Lab., Tenn.), from Astron. Raumfahrt; No. 2, 58-61(1969). 5p. Dep. NTIS.

Data on the mean radiation doses absorbed by American and Soviet astronauts, as recorded by individual dosimeters during 18 space flights are presented as evidence that manned missions can be carried out with relatively slight exposure to radiation. The possible hazards of radiations for the personnel of space stations are considered, with emphasis on the hazards during solar flares. It is concluded that continual surveillance of solar activity and the provision of a shielded room to which the crew could retire during solar flares would provide adequate protection. Estimates of shielding requirements at various heights and orbital inclinations are included. (C.H.)

58026 ZASHCHITA ZHIVOTNYKH OT PORAZHENIYA YADERNYM ORUZHIEM. (Protection of Animals Against Injury by Nuclear Weapons). Karavaev, V. M.; Kolyakov, V. L.; Korzhevenko, G. N.; Il'in, V. G. Moscow; Izdatel'stvo Kolos (1970). 400p.

Types of injuries observed in domestic animals exposed to shock waves and radiations from nuclear weapons are discussed. Veterinary methods for the handling of irradiated animals are described. Shielding precautions necessary for the protection of domestic animals against injuries caused by nuclear weapons are described. Radiation syndromes, diagnostic methods, and methods for examining hides, organs, and tissues of irradiated animals for possible salvage are reviewed. Radiation dosimeters, ratemeters, and probes designed for use in the field are described. (280 references.) (K.S.W.)

Safety Procedures

58027 OPERATIVE STATUTES OF RADIATION PROTECTION. Feher, L.; Gacs, F. Izotoptechnika; 14: No. 3, 35-49 (Mar 1971). (In Hungarian).

Hungarian regulations and statutes directed toward safety in work with radiation sources are reviewed and evaluated. (D.E.B.)

Legal Aspects

58028 (BRH/DMRE-71-4) STATE AND FEDERAL CONTROL OF HEALTH HAZARDS FROM RADIOACTIVE MATERIALS OTHER THAN MATERIALS REGULATED UNDER THE ATOMIC ENERGY ACT OF 1954 (AS OF OCTOBER 1, 1969). Pettigrew, George L.; Robinson, Earl W.; Schmidt, Gail D. (Bureau of Radiological Health, Rockville, Md. Div. of Medical Radiation Exposure). Jun 1971. 101p. GPO $1.00.

A study was made of State and Federal regulatory control of radium and accelerator-produced materials in the USA. A review of health hazards, a determination of the extent and magnitude of use, and an evaluation of the gaps and inconsistencies in present control of such materials are presented. The study revealed that radium is still used extensively in industry, medical applications, and consumer products. Despite this widespread use, which dates back many years, radium use is not regulated uniformly by all State and Federal agencies, nor is the control compatible with that exercised over AEC-regulated materials. Furthermore, there is no Federal authority to establish uniform and compatible use standards nor to require that sources and devices containing radium or accelerator-produced materials be manufactured or imported in accordance with minimum product safety standards. (auth)

58031 CHANGE IN THE LEVEL OF REDOX POTENTIAL IN MUSCLES OF DIFFERENT ANIMAL SPECIES AS A FUNCTION OF THE DOSE OF CYSTAMINE INTRODUCED. Vladimirov, V. G.; Yusipov, V. S.; Poddubskii, G. A. (Military-Medical Academy, Leningrad). Radiobiologiya; 11: No. 1, 102-5(1971). (In Russian).

The influence of various doses of cystamine after intravenous injection on the level of the redox potential in the muscle was studied in experiments on mice, rats, and dogs. It was shown for all the species of animals that the decrease in the redox potential is directly proportional to the dose of the protector; however, in different species, within a definite dose range, the decrease in the redox potential is inversely dependent upon the level of metabolism in the animal organism. On the basis of the experimental data obtained, a formula was proposed that reflects the ratio of the doses of cystamine in mice and dogs, equally effective with respect to their ability to change the redox potential in the muscles of these animals. (tr-auth)

58032 RADIOPROTECTIVE ACTION OF VERSENE ON GAMMA IRRADIATED BACTERIOPHAGES. Masironi, Roberto; Kriviskii, Alexander S. (Inst. of Molecular Biology, Moscow). Riv. Biol.; 61: No. 1, 35-41(Jan-Mar 1968). (In Italian).

Bacteriophages used in the investigation were T_2, ϕX174, N 1, and Sd. Suspensions of phage were diluted in phosphate buffer at pH 7.2 and gamma-irradiated as follows: in the dry state, in 4% nutrient broth, in phosphate buffer, in phosphate buffer containing versene, in broth containing versene, and in phosphate buffer with versene added after irradiation. Results indicated that versene was a good radioprotective agent. Contrary to results of ultraviolet radiation experiments, versene was effective when employed in complex form and when added after irradiation. Phage ϕX174 was protected against gamma radiation, but not against ultraviolet radiation. (H.L.W.)

58033 EFFECT OF TISSUE PREPARATIONS ON IRRADIATED LABORATORY ANIMALS. Shcheglov, S. M. Cesk. Radiol.; 24: No. 5, 215-16(Sep 1970). (In Russian).

The biological effect was studied of SEP (a bone marrow preparation) and antianemin on the survival of mice X-irradiated with 350, 400, and 500 R, and of complex preparation GS-7 (a preparation stimulating haemopoiesis) and of SEP on the survival of rabbits irradiated with 1100 R. Results are also presented of the differential blood count. All preparations were found to favourably affect the survival of irradiated animals; GS-7 was the most effective preparation, the effectivity of SEP was lower, and that of antianemin the lowest of the three. Due to its biological properties, the GS-7 complex preparation has a stimulating effect on blood formation; this makes it valuable for radiation pathology. (NSA of Czech)

58034 IN VIVO STUDIES OF RADIATION POTENTIATION BY IODOACETAMIDE AND OBSERVATIONS ON TUMOR TRANSPLANTATION IMMUNITY. Richards, William Robert. Berkeley, Calif.; Univ. of California (1970). 124p. University Microfilms Order No. 71-20,898.

Thesis.

Iodoacetamide has been shown by others to be a radiation sensitizer for bacteria and for certain mammalian cells tested in vitro. This work describes an examination of the effectiveness of iodoacetamide used in vivo. Survival of ascites tumor cells maintained in the peritoneal cavity of mice was used as an indicator of sensitization. Survival was assessed using TD_{50} and total tumor cell population determination methods. A comparison of results obtained by these methods is made. The effects of oxygen tension and radiation dose rate upon results was examined. Iodoacetamide was found to be effective as a radiation sensitizer under all conditions although to a lesser degree than that reported by others for in vitro experiments with bacteria. Radioactive tracer studies indicate that iodoacetamide has rapid and total access to most if not all tissues of the body. This fact coupled with the observation of a sensitization in an in vivo system where the anoxia so prevalent in well developed tumors was present, suggests the possibility of clinical usefulness of iodoacetamide in cancer radiation therapy. Certain observations are reported on the effect of various cell and host treatment procedures upon cell population growth kinetics seen subsequent to inoculation of hosts with the cells. A hypothesis is presented which can account for the observations made by the author and also for those made by some others who report that large inocula, i.e., greater than 10 cells, are required to give rise to a lethal tumor in isologous hosts of the strain of tumor origin. The hypothesis may also account for what is known in the literature as the "Hybrid Effect." (Diss. Abstr. Int., B)

58035 INFLUENCE OF ADRENAL CORTEX TOTAL EXTRACTS ON RADIATION SICKNESS. Hartmann, U.; Soost, H.-J. (Univ., Munich). Ther. Gegenw.; 110: 539-45(Apr 1971). (In German).

In a double-blind clinical study, 61 patients with cervical cancer received either 6 mg of total adrenal cortex extract or a placebo following radiotherapy. The initial reaction to radiation was then compared. Statistical evaluation of the data revealed no significant difference between adrenal cortex and placebo groups; however, clinical observations indicated enough improvement of the treated group to justify continuation of the study. (H.B.G.)

58036 EXPERIMENTAL STUDY OF AGENTS PROTECTING THE SKIN AGAINST ACUTE RADIATION ULCERATION. Chaudhuri, S. K.; Lal, K.; Chakravarti, R. N. (Post-Graduate Inst. of Medical Education and Research, Chandigarh, India). Indian J. Med. Res.; 58: 1413-20(10 Oct 1970).

An experimental study on rabbits was undertaken to investigate the effect of x-irradiation on the skin and to evaluate the role of methionine, desoxycorticosterone acetate, vitamin A and local wound as protective agents against acute radiation ulceration. X-irradiation was given and the animals were observed for a maximum period of 65 days. The parameters of study for therapeutic evaluation were general condition, body weight, naked eye study of the post-irradiation reactions, measurement of post-irradiation wound and histological examination of skin from the irradiated and unirradiated areas. These studies were done at different periods. The control as well as animals treated with methionine and DOCA invariably had post-irradiation reactions, but only three and two animals treated with vitamin A and prior wound respectively showed some evidence of post-irradiation reaction. Healing of the post-irradiation wounds by scab formation was a common feature in all the animals showing post-irradiation reactions. The scab fell off leaving a glistening pearly white soft apparently normal skin. A statistical assessment showed maximum amount of tissue necrosis in control animals, while it was minimum in vitamin A treated animals. The difference as regards amount of tissue necrosis, was highly significant ($p < 0.01$). Production of prior wound at the site of irradiation retarded tissue necrosis to a marked degree. (auth)

Radiation Sickness and Injuries

58037 TUMORS OF THE SKIN. XII. TOPICAL 5-FLUOROURACIL FOR EPIDERMAL NEOPLASMS. Klein, Edmund; Stoll, Howard L. Jr.; Milgrom, Halina; Helm, Frederick; Walker, Mary J. (Roswell Park Memorial Inst., Buffalo). J. Surg. Oncol.; 3: No. 3, 331-49(1971). (CONF-690457-2).

From Symposium on recent advances in the management of skin neoplasms; New York, N. Y. (11 Apr 1969).

The optimal dose of topical 5-fluorouracil in late radiation dermatitis in man varies with the extent of the dermatitis and the type of lesions. The dose was determined in a group of 17 patients by progressive increase in the concentration from 0.05% 5-FU until a concentration was reached which gave an adequate response without untoward intensity of local side-reactions. Late radiation dermatitis in areas other than the face, such as the back, the neck, and the upper arms, usually responded satisfactorily to a 5% 5-FU concentration. Individual lesions persisting after topical treatment to larger areas were treated with concentrations of up to 20% 5-FU. The adjacent skin frequency showed an inflammatory reaction to the higher concentrations of 5-FU which subsided within five to seven days. Healing of the sites of lesions may require two to four weeks after terminating chemotherapy. (auth)

58038 RADIONECROSIS OF THE SKIN. TASKS FOR A MEDICAL GROUP. Drepper, H.; Ehrings, F.; Vojtech, D. (Westfaelische Vereins fuer Krebs- und Lupusbekaempfung, Muenster, Ger.). Med. Welt; 5: 155-62(30 Jan 1971). (In German).

When ulcers occur in atrophic skin caused by x radiation, possibility of malignancy must be excluded as a first step. Malignancies can be either radioinduced or metastatic. Various types of conservative treatment of radiation ulcers are discussed with respect to solutions, ointments, and antibiotics. If tissue necrosis is too deep, exposed to too much tension, and caused by too high radiation doses, plastic surgery becomes necessary. Coverage by skin flaps, full thickness skin grafts, and split skin grafts are discussed. (H.B.G.)

58039 REGIONAL APPROACH TO THE MANAGEMENT OF RADIATION ACCIDENTS. Linnemann, Roger E.; Thiessen, Joop W. (Radiation Management Corp., Philadelphia). Amer. J. Public Health; 61: No. 6, 1229-35(Jun 1971).

A regional program for the management of radiation accidents represents a feasible and practical answer to a major challenge associated with the nuclear age. By coordinating the medical capabilities of a regional treatment center with those of supporting hospitals and potential accident sites, this plan appears to be the most effective means of discharging the nuclear community's obligation to the public, and the medical profession's responsibility to the nuclear community. 58040 (UCLA-12-834) COMPARISON OF RADIOAEROSOL VERSUS RADIOXENON INHALATION PROCEDURES IN OBSTRUCTIVE LUNG DISEASE AND PULMONARY EMBOLISM. Taplin, George V.; Poe, Norman D.; Isawa, Toyoharu; Dore, Earl K. (California Univ., Los Angeles. School of Medicine). [1971]. Contract AT(04-1)-Gen-12. 33p. Dep. NTIS.

The advantages of scintillation camera lung imaging following the injection of ^{99m}Tc-labeled albumin macroaggregates, the inhalation of ^{113m}In-labeled albumin aerosols, and the inhalation of ^{133}Xe for the evaluation of blood perfusion and ventilation and the localization of even relatively small lung neoplasms are discussed. It is pointed out that perfusion and inhalation lung imaging should be performed in rapid sequence whenever underlying obstructive airway disease is suspected. The combined data from both perfusion and inhalation lung imaging is useful for the diagnosis and localization of neoplasms, disturbances in air flow dynamics and regional ventilation, emphysema, pulmonary embolisms, and disturbances in blood circulation. (C.H.)

58041 (UCLA-12-837) COMPARATIVE MYOCARDIAL UPTAKE AND CLEARANCE CHARACTERISTICS OF POTASSIUM AND CESIUM. Poe, Norman D. (California Univ., Los Angeles). [1971]. Contract AT(04-1)-Gen-12. 13p. Dep. NTIS.

Potassium-43 and its analog, cesium-129, have recently been suggested as suitable radiopharmaceuticals for myocardial scanning. Studies with potassium-42 and cesium-131 were undertaken in dogs to determine the myocardial turnover characteristics of these two ions. After simultaneous intravenous injection, potassium clears rapidly from the blood, reaches a plateau in the myocardium within 5 to 20 minutes, and then clears with a T 1/2 of 6.5 hours. Initial cesium clearance is slower. A peak is reached gradually in the myocardium within 1 to 3 hours and the clearance T 1/2 is 27.3 hours. Following intracoronary injection, potassium is extracted with 71% efficiency on a single circulation, but cesium is extracted with only 22% efficiency. It is concluded that cesium should be utilized with caution as a substitute for potassium in quantitative myocardial blood flow and function measurements, but that comparable results can be obtained with either radionuclide in localizing ischemic myocardium. (auth)

58042 STUDIES ON LIVER FUNCTION TEST WITH ^{131}I BSP MONOIODIDE AND SCINTICAMERA. Torizuka, Kanji; Hamamoto, Ken; Morita, Rikushi; (and others) (Kyoto Univ.). Amer. J. Roentgenol., Radium Ther. Nucl. Med.; 113: No. 1, 41-9(Sep 1971).

From the studies on the usefulness of ^{131}I-bromosulphalein (BSP) for the liver function test with scinticamera, 1600 channel pulse height analyzer, and digitizing magnetic tape recorder, the following procedure is recommended as routine for obtaining the liver function and liver visualization: the blood is drawn at 10 minutes after the intravenous administration of 150 μc ^{131}I BSP monoiodide; the percent retention of ^{131}I BSP in serum at 10 minutes is estimated from the ^{131}I BSP concentration in serum at 10 minutes, and the total serum volume obtained from the body weight and body height. The scintigraphy is performed at 30 to 60 minutes. (auth)

58043 EFFECTS OF pH ON ^{113m}In DISTRIBUTION, IN ORDER TO SIMPLIFY THE PREPARATION OF ^{113m}In FOR BLOOD POOL AND LIVER SCANNING. Watanabe, Katsushi (Kyushu Univ., Fukuoka); Kawano, Yoshiaki. Kaku Igaku; 7: No. 1, 8-15(May 1970). (In Japanese).

The effects of pH on ^{113m}In distribution in mice were studied to determine how precisely pH should be adjusted. Activity of ^{113m}In in blood was high at pH 3.5 ± 1.0 both with and without heating. Therefore, blood pool scanning can be done sufficiently with ^{113m}In solution in this range of pH value. The liver concentration reached approximately 78% at pH 10.5 without heating and over 70% in the range of pH 10.5 ± 0.5. With heating, the liver concentration of ^{113m}In was approximately 80% at pH 8.5 to 9.5 and over 70% in the range of pH 9.5 ± 1.0. Incubation led to higher liver concentrations. However, liver scanning can be done effectively with ^{113m}In adjusted to pH 10.5 ± 0.5 without heating. It was found that ^{113m}In use for blood pool scanning and liver scanning did not require strict adjustment of pH. In the preparation of ^{113m}In for this purpose, pH measurement and autoclaving can be omitted by using a sterile generator and sterilized reagents. (Japan)

58044 ANGIOGRAPHY, SCINTILLATION SCANNING, AND ULTRASOUND TOMOGRAPHY OF THE LIVER. Fuchs, W. A.; Voegeli, E.; Schwegler, N.; Huenig, R.; Roesler, H. (Univ., Bern). Schweiz. Med. Wochensch.; 32: No. 101, 1180-6(14 Aug 1971). (In German).

A comparative study of angiography, scintillation scanning, and ultrasound tomography in the diagnosis of space-occupying lesions of the liver was made in 20 patients. Ultrasound tomography and scintillation scanning are screening methods which provide a more precise indication for angiography. (auth)

58045 POSITIVE SCINTIPHOTOGRAPHY OF CANCER OF THE LIVER WITH ^{67}Ga CITRATE. Suzuki, Takashi; Honjo, Ichio; Hamamoto, Ken; Kousaka, Tadako; Torizuka, Kanji (Kyoto Univ.). Amer. J. Roentgenol., Radium Ther. Nucl. Med.; 113: No. 1, 92-103(Sep 1971).

Twenty-five patients with histologically proven cancer of the liver were studied with liver scintiphotography using ^{67}Ga citrate. Of 25 cases, five (four hepatomas, one metastatic cancer) showed increased uptake of ^{67}Ga citrate in the tumor, eight (three hepatomas, one cholangioma, four metastatic cancers) showed equilibrated uptake, six (all metastatic cancers) showed decreased uptake, and the remaining six (two hepatomas, four metastatic cancers) showed undetermined uptake. Of the cases in which ^{67}Ga citrate in the tumor showed poor uptake, three had effective treatment of the lesions prior to the study. (auth)

58046 SCINTILLATION SCANNING OF LIVER CELL ADENOMA. Sackett, Joseph F.; Mosenthal, William T.; House, Reginald K.; Jeffery, Robert F. (Mary Hitchcock Memorial Hospital, Hanover, N. H.). Amer. J. Roentgenol., Radium Ther. Nucl. Med.; 113: No. 1, 56-60(Sep 1971).

Scintillation photoscannings with ^{99m}Tc sulfur colloid and ^{131}I rose bengal were performed in a 33 year old female before and after partial liver resection for benign adenoma. The benign nature of the functioning liver cell adenoma, seen in the photoscans, correlates well with the gross and microscopic pathologic changes. The adenoma takes up both radionuclides to almost the same degree as normal liver tissue. (auth)

58047 PROCESS OF MANUFACTURING RADIOACTIVE SUBSTANCES DERIVED FROM DIFLUORESCENYLMERCURY AND LABELLED WITH RADIOACTIVE IODINE ISOTOPES. Ratusky, Josef; Kronrad, Leo; Malek, Prokop; Kolc, Jiri; Vavrejn, Bohuslav (to Ceskoslovenska Akademie Ved). British Patent 1,240,786. 28 Jul 1971. Priority date 20 Dec 1968, Czechoslovakia.

A method is presented for the preparation of ^{125}I- or ^{131}I-labeled difluoresceinylmercury compounds, which are seen to be superior for clinical diagnosis of ischemically injured tissues or experimental work to their currently used ^{197}Hg- or ^{203}Hg-labeled sister compounds. Radioactive iodinated fluorescein derivatives may be prepared synthetically or by exchange reactions. These derivatives are reacted with compounds of bivalent mercury, as illustrated by the following equations: fluorescein + $HgX_2 \rightarrow$ XHg-fluoresceinyl + HX; and, XHg-fluoresceinyl + fluoresceinyl $\rightarrow$ fluoresceinyl-Hg-fluoresceinyl + HX. (J.G.B.)

58048 SCHILDER'S DISEASE. POSITIVE BRAIN SCAN. Valenstein, Edward (Harvard Medical School, Boston); Rosman, N. Paul; Carter, Anthony P. J. Amer. Med. Ass.; 217: No. 12, 1699-1700(20 Sep 1971).

A case history is presented for a 12-year old boy with a diagnosis of Schilder's disease in whom a ^{99m}Tc brain scan showed abnormal findings. (C.H.)

58049 HANDBOOK FOR TECHNOLOGISTS OF NUCLEAR MEDICINE. Hudak, Julia S. Springfield, Ill.; Charles C Thomas, Publisher (1971). 163p. $8.75.

Procedures using radioisotopes for in vivo and in vitro clinical diagnostic tests are outlined. The characteristics and operation of radiation detection instruments used routinely and methods for sample preparation are described. The purpose of each test, the dose of each radioisotope administered, the interpretation of results, and guidelines and contraindications for the administration of each radioisotope are included. Precautions to be taken to

XUM

minimize the radiation exposure of both patients and personnel are described. (47 references.) (C.H.)

58050 A NEW AGENT FOR LIVER SCANNING: $^{131}I-T_3$. Tatsuno, Ikuro (National Hospital of Kanazawa, Japan). Kaku Igaku; 7: No. 2, 111-17(Jun 1970). (In Japanese).

Patients were injected with ^{131}I labeled triiodothyronine ($^{131}I-T_3$) and scintiscans were made of the liver. Excellent scintigrams were obtained and several advantages were noted when compared with $^{131}I-T_4$ (^{131}I-thyroxine) or ^{198}Au colloid. Maximum radioactivity, and sufficient to scan the liver, was reached about 5 min after intravenous injection of $^{131}I-T_3$, whereas 120 to 180 min were required with $^{131}I-T_4$, so that scanning could be started immediately after the injection of $^{131}I-T_3$. The space-occupying lesion in the liver, confirmed by autopsy, was more accurately and clearly delineated than when using colloidal ^{198}Au. The biological half-time of $^{131}I-T_3$ in the liver was 2 to 3 hrs compared to 30 to 90 hrs with $^{131}I-T_4$. The radiation dose to the liver from $^{131}I-T_3$, $^{131}I-T_4$, and ^{198}Au was determined by the Quimby formula. The radiation dose to 1,200 g of liver (which is the average weight for Japanese males) from 200 μCi of $^{131}I-T_3$ was approximately 0.25 rad. Thus the radiation dose can be reduced to $^1/_{25}$ that received from 120 μCi of colloidal ^{198}Au, the most widely used tracer dose in this department. (auth)

58051 USE OF RADIOACTIVE TRACERS IN THE STUDY OF BREAST CANCER. Tarolo, G. L. (Univ., Milan); Colombo, L.; Calvi, A. Radiol. Med.; 56: No. 11, 1036-48(Nov 1970). (In Italian).

Radioactive tracer uptake was determined in 42 patients with unilateral breast nodules awaiting biopsy or mastectomy. The tracers employed were ^{32}P, ^{197}Hg, and ^{75}Se. Comparison with the histological data showed: that ^{197}Hg bichloride gave the smallest number of false negatives; that slight uptake occurred in some benign nodules, with values approaching those considered typical of malignancy in rare instances; and that uptake was quantitatively determined by the growth rate of the neoplasm. It was concluded that this method is less useful as screening test than in the study of the metabolic and development features of known or suspected malignant tumors for the purpose of obtaining reliable information with respect to prognosis and planning of treatment. (auth)

58052 ^{111}In: A NEW RADIOISOTOPE FOR CYSTERNOSCINTILLOGRAPHY. Fuenzalida, S.; Bennett, L. R.; Larson, J. M. (Univ. of California, Los Angeles). Rev. Biol. Med. Nucl.; 3: No. 1, 25-9(Feb 1971). (In Spanish).

Most of the centers are employing ^{131}I-albumin and more recently ^{99m}Tc-albumin for cisternoscintigraphy. ^{111}In-albumin gives advantages over both. ^{111}In has a half life of 2.8 days which is useful when late controls are necessary. It has very good γ energies, 173 and 274 keV, similar to ^{99m}Tc, and a minimum contribution of internal conversion electrons. This produces an irradiation dose smaller than ^{131}I. A method for the preparation of the ^{111}In-albumin with a high specific activity is described. Serial cisternoscintigrams were obtained in 12 adult dogs following the injection of 1 mCi intracisternally using a magnascanner. Excellent cisternoscintigrams were obtained within 3 hours and 7 days. These studies suggest that ^{111}In-albumin can be the compound of choice for cisternoscintigraphy. (auth)

58053 STUDY OF THE RETICULOENDOTHELIAL SYSTEM IN HEMATOLOGICAL DISEASES. Dibos, P. E.; Spaulding, M. B.; Judisch, J. M.; Wagner, H. N. Jr.; McIntyre, P. A. (Johns Hopkins Medical Institutions, Baltimore). Rev. Biol. Med. Nucl.; 3: No. 1, 30-5(Feb 1971). (In Spanish).

A study was made in order to evaluate the usefulness of the visualization of the liver, the spleen, and the functional bone marrow in patients with hematological diseases. More than 180 scintigraphic studies were made; all of them with ^{99m}Tc-colloidal and Anger Camera. All the patients with polycythemia vera (eleven) showed a marked hyperplasia of the bone marrow reticuloendothelial system (RES). But in cases of polycythemia due to stress, the images were normal. The twelve patients with myelofibrosis showed a serious bone marrow hypoplasia. A significative distal expansion was observed in cases of chronic hemolitic anemia, pernicious anemia, and iron deficiency. Fourteen patients with Hodgkin's disease (degrees III and IV) and 20 patients with other lymphomas were studied. All these patients showed abnormalities in the RES scintigrams, and six of eight patients with myeloma showed a severe hypoplasia of the bone marrow RES. These studies show that the RES images, including liver, spleen, and bone marrow, can be useful in the differential diagnosis of polycythemias and myeloproliferative diseases and in the determination of lymphoma clinical state. (auth)

58054 ^{75}Se-SELENOMETHIONINE IN THE SCINTALLOGRAPHY OF THYROID AND HEPATIC LESIONS. Maisterrena, Jorge A.; Tovar Z., Enrique; Cervantes, Abelardo; Tello R., Carlos (Instituto Nacional de la Nutricion, Mexico City). Rev. Biol. Med. Nucl.; 3: No. 1, 18-24(Feb 1971). (In Spanish).

Thyroid nodules that do not concentrate iodine represent a medical problem. Hepatic lesions that show themselves as a defect of radioactive colloid concentration are in the same category. The scintigraphy of these lesions with ^{75}Se-selenomethionine gives information that helps to resolve this problem to a certain degree. Results are reported from a study that consisted in the administration of 250 microcuries of ^{75}Se-selenomethionine intravenously and obtaining a scintigram at 1, 24, 48, and 72 hours over the area of interest. The material consisted of ten patients with thyroid lesions and five patients with hepatic lesions. The thyroid nodules having a great cellularity concentrated more amino acid than the surrounding tissues. In the liver, the primary tumors concentrated the amino acid also perhaps because it is a tissue with protein synthesis capacity. The scintigram with ^{75}Se-selenomethionine suggested that the degree of cellularity and/or the capacity to synthesize proteins in the studied tumors is related to the amino acid concentration degree. In all the cases in which a histological study was made, there was a good correlation between protein synthesis and the scintigraphic findings. (auth)

58055 CLINICAL IMPORTANCE OF THE STUDY OF THE LYMPHATIC SYSTEM WITH RADIOISOTOPES. Harbst, Hans; zum Winkel, Karl (Freie Univ., Berlin). Rev. Biol. Med. Nucl.; 3: No. 1, 11-17(Feb 1971). (In Spanish).

The examination of the lymphatic system with radioisotopes is based on the absorption of a labeled colloidal substance. Lymph node metastases of solid tumors and displacements of the node chains or blockage of the lymphatic ducts are shown on the scintigram. In the inflammatory processes, the quantity of substance fixed by the lymphatic RES is reduced compared with the normal lymphatic nodes. Malignant lymphoma appears as a diminution in the uptake of the radioactive tracer in large lymphatic areas. The comparative study of scintigraphy with the direct radiography, using lipiodol, of the abdominal lymphatic chains made on 460 patients showed that in 70% of the cases with normal scintiscans or with evident pathological alterations the radioisotopic study was sufficient. In 30% of the cases, the scintiscan had to be supplemented with Lipiodol lymphography. The scintigram was useful in the representation of the abdominal, axilar, supraclavicular, and cervical lymphatic chains. The study of the retrosternal lymphatic system is of great importance, especially for patients with breast tumor, before and after radiotherapy. The uptake by some lymph tumors of citrates labeled with ^{67}Ga administrated intravenously has opened new possibilities for the early diagnosis of some malignant disorders of the lymphatic system. (auth)

58056 LEAKAGE PHENOMENON IN THYROID GLAND TUMORS. Roesler, H. (Univ., Bern). Electromedica; No. 5, 312-20(1970).

Serial scintigraphy of the thyroid gland allows the identification of regional differences in the accumulation and elimination of ^{131}I in the gland. The leakage phenomenon, which proves an accelerated elimination of radioactive iodine, is described in tumors of benign and malignant histology with effective and ineffective iodine metabolism. This phenomenon is seen in toxic adenoma with strongly increased PBI-131 and, in a case of struma maligna Langhans, was an additional indication of a functional dedifferentiation of the tumor and of a clinical cause of an accompanying hyperthyroidism. In the case of a solid thyroid gland carcinoma, the spontaneous leakage phenomenon was the result of an iodization insufficiency peculiar to the tumor. This faulty utilization of iodine was proved by a control series with perchlorate loading in which the serial scintigraphy provided the finding of an exogenous accelerated leakage phenomenon. Toxic adenomas with a positive leakage phenomenon should be treated by surgery. Also in the case of proven iodine insufficiency, the radical operation and the subsequent, high-dose and repeated treatment with radioactive iodine of the struma maligna are justified. (auth)

58057 RECTILINEAR SCANNING. Deland, F. H. (Univ. of Florida, Gaineville). Electromedica; No. 3, 80-2(1971).

Radionuclide imaging reveals lesions as either an area of increased or decreased radioactivity relative to the surrounding level of activity. In larger organs the tomographic effect of rectilinear instruments enhances the detection of deeper lesions. The dual probe scanners, which provide two images simultaneously, provide markedly decreased examination time and permit more thorough examination of the patient and improved diagnosis. (auth)

58058 MEASURING THE BLOOD FLOW THROUGH THE BRAIN WITH THE AID OF ^{133}Xe. Hacker, H. (Johann-Wolfgang-Goethe Univ., Frankfurt am Main). Electromedica: No. 2, 189-94(1970).

Recording of the loss of radioactivity in circumscribed regions of the brain after injection of ^{133}Xe in the internal carotid artery makes it possible to calculate the regional cerebral blood flow from the washout curve. The procedure adopted for such investigations is described that led to new ideas about cerebral vasomotoricity and made possible a more exact diagnosis of cerebral ischaemic conditions. (auth)

58059 EVALUATION OF PHOTO-SCINTIGRAMS BY MEANS OF TELEVISION REPRODUCTION AND SUBTRACTION. **Feine, U. (Univ., Tuebingen, Ger.). Electromedica: No. 2, 42-4(1969).**

A technique for the evaluation of photoscintigrams is described which employs contrast intensification of the television image and, specially for pancreas scintigraphy, the subtraction of two television images. This method is also suitable for the subsequent evaluation of poorly exposed photoscintigrams. The method of double labeling the liver in pancreas scintigraphy with ^{75}Se-methionine and ^{198}Au colloid was used. (auth)

58060 SCINTIGRAPHIC DIAGNOSIS BY MEANS OF SHORT-LIVED RADIONUCLIDES. **Wolf, F.; Kroenert, E. (Univ., Erlangen, Ger.). Electromedica: No. 2, 33-7(1969).**

The advantages of using short-lived metastable radioisotopes for scintigraphic diagnostic studies are discussed. The properties of ^{99m}Tc and ^{113m}In are described and their scope of practical application is demonstrated by scintigraphic studies of the brain, liver, stomach wall, and placenta. (C.H.)

58061 SOME PRACTICAL CONSIDERATIONS ON PANCREATIC SCANNING. **Iwig, J. (Johanniter-Krankenhaus Rheinhausen, Kreuzacker, Ger.). Electromedica: No. 4, 258-60(1970).**

A technique for scintigraphy of the pancreas following the intravenous injection of ^{75}Se-selenomethionine is described. A method for patient preparation and positioning is described that eliminates the need for simultaneous ^{198}Au liver subtraction scanning. The method produced good scintigrams of normal and pathological pancreas in a series of 160 studies. (C.H.)

58062 NEW EVALUATION AND GRAPHIC REPRESENTATION OF SCINTIGRAPHY: THE CURVE SCAN. **Seyss, Ruediger. Radiol. Clin. Biol.; 40: No. 4, 261-9(1971). (In German).**

A modification of radioisotope scanning with statistical analysis of data is described which permits a continuous quantitative representation of the activity distribution in the examined organ. The technique is explained and the advantages of this method are described. (auth)

58063 MEDICAL PROBLEMS IN EYE TUMOR IDENTIFICATION. **Larose, James H.; Jarrett, W. H.; Hagler, William S.; Palms, John M.; Wood, Robert E. (Emory Univ., Atlanta). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 46-9(Feb 1971).**

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).
NSA

The diagnostic accuracy of the ^{32}P uptake test for differentiating between benign and malignant melanomas of the eye is discussed. A method for administering the test, in which a meticulous surgical procedure is used to ensure adequate localization of the suspected lesion and direct placement of the radiation detector over the lesion, is described. (C.H.)

58064 EYE TUMOR IDENTIFICATION TESTS USING SEMICONDUCTOR DETECTORS. **Palms, John M.; Wood, Robert E.; Larose, James H.; Jarrett, W. H.; Hagler, William S. (Emory Univ., Atlanta). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 50-6(Feb 1971).**

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

A comparison was made of the performance of the conventional Geiger–Mueller eye probe and several eye probes using semiconductor detectors for measurements of the low-energy β radiation emitted by tracer doses of ^{32}P used for the diagnosis of eye melanomas. Silicon lithium drifted [Si(Li)], silicon surface barrier, and silicon avalanche β detectors were tested. The results indicate that the Si(Li) posterior probe detector gave the most consistent, sensitive, and reliable results. (C.H.)

58065 PROCESSING DATA IN NUCLEAR MEDICINE WITH THE AID OF DESK-TOP COMPUTERS. **Feine, U.; Ehrke, F.; Knorr, D.; Kueper, K. (Univ., Tuebingen, Ger.). Electromedica: No. 2, 64-8(1970).**

The amount of digital data that must be handled each day in a nuclear medical department is so great that much time is lost despite the simplicity of the calculation in most cases. Particularly with the automatic measurements involving sample changers, the technical assistant is confronted with long columns of figures that have to be dealt with. Automatic data processing with desk-top computers in on-line operation greatly speeds up the calculation time. (auth)

58066 AUTOMATIC EXPOSURE IN TOMOGRAPHY. **Stieve, F. E. (Univ., Munich). Electromedica: No. 4, 131-5(1969).**

Fundamental considerations for obtaining satisfactory radiographs using tomographic techniques with automatic exposure timing are presented. Both conventional radiographs and those made following the administration of contrast media are discussed. It is pointed out that tomograms obtained using automatic exposure techniques provide uniform picture quality and improved homogeneity resulting from the larger effective exposure angle and the uniform transirradiation at all angles of incidence. (C.H.)

58067 STATISTICAL EVALUATION OF IMAGE IN SCINTIGRAPHY. **Baer, G. (Siemens AG, Erlangen, Ger.). Electromedica: No. 3, 235-7(1970).**

The quality of visual readability of a scintigram is determined by a number of parameters of which the maximum count rate (counts/min) found on the organ under examination, the scanning speed (cm/min) of the detector, and the count rate to be subtracted (counts/min) are especially important. These typical specifications permit a Q value to be found which gives information on the expected quality (statistical evaluation) of the scintigram to be taken. If the settings are selected in such a way that always the same statistical Q value is obtained with different scintigrams, these are necessarily of the same quality provided the other parameters, such as collimator dimensions, focus distance, and photo peak confinement are kept constant. Scintigrams taken in this manner meet the technical requirements necessary for comparison and test examinations. (auth)

Radiotherapy

58068 RADIATION THERAPY OF SKIN CARCINOMA. **Murphy, Walter T. (Buffalo General Hospital). J. Surg. Oncol.; 3: No. 3, 291-308(1971). (CONF-690457–1).**

From Symposium on recent advances in the management of skin neoplasms; New York, N. Y. (11 Apr 1969).

X radiation therapy of basal or squamous cell carcinomas of the skin is successful in most patients. This is true even in problem patients such as those with lesions over 10 cm in greatest diameter; lesions invading muscle, cartilage, or bone; lesions in extremities; lesions recurrent under surgical skin reconstruction; and lesions in chronic radiodermatitis. The irradiation sources should be skillfully applied by clinicians trained in the radiotherapeutic aspects of skin cancer. (auth)

58069 RADIOTHERAPY OF BRAIN TUMORS. **Okawa, Tomohiko; Miyazaki, Taiichi (Hiroshima Univ.). Hiroshima Igaku; 23: No. 8, 644-7(Aug 1970). (In Japanese).**

Brain tumors were irradiated with ^{60}Co γ rays by fixed bilateral irradiation from a Toshiba Model 107 machine. The initial dose rate was 50 R/day. This was gradually increased to 200 R/day at 2 weeks where it was maintained to give a 5000 R dose in 5 to 6 weeks. Of the total of 82 irradiated cases, 30 cases had received surgery (total and partial resection) before radiation, 52 cases were inoperable (23 cases of which had undergone low-pressure operation), and the remainder consisted of 11 cases of A-V malformation, three cases of clinical pituitary tumor, and five cases of metastatic tumor. Of these cases, 63 (76.8%) received more than 5000 R focal dose and 13 received more than 4000 R. Primary effectiveness in 52 cases given irradiation alone was rated as markedly effective in 27 cases, effective in seven cases (total of 84.6%), and ineffective in eight cases (including two cases of A-V malformation, three cases of astrocytoma, and three cases of clinical glioma). In 30 cases of postoperative irradiation, marked effectiveness was found in five cases, effectiveness in 24 cases (total of 96.6%), and ineffectiveness in only one case (an astrocytoma given 5000 R irradiation). Six-month survival rate in the irradiation alone cases was 25 out of 42 (59.5%), and for the postoperative irradiation cases it was 20 out of 24 (83.3%) making a total of 45 out of 66 (68.2%). Survival for 1 to 3 yrs was observed, but 5-yr survival cannot be calculated yet. Irradiation seemed effective for A-V malformation, and postoperative irradiation was effective for pituitary tumor. These results indicate that 5000 R may be taken as the tolerable dose for the brain. In the cases with poor results, the reason seems to be insufficiency of irradiation dose and too small an irradiated field. Examinations are required for irradiation of a large field with 6000 to 7000 R. (Japan)

58070 CLINICAL STUDIES ON THE RADIATION THERAPY IN CANCER OF THE UTERINE CERVIX. Kimura, Mitsuo (Tokyo Hospital). Gan No Rinsho; 16: No. 7, 721-36(Jul 1970). (In Japanese).

Therapeutic results are reviewed for external irradiation of uterine cervical carcinomas using super-high voltages in the Gynecology Clinic of the Cancer Institute Hospital, Tokyo. External irradiation was performed using deep x rays (1950 to 1959), telecobalt (1960 to 1963), and linac x rays (1964 to 1966). There were no significant differences among these irradiation methods for both 5-yr and 3-yr survivals, but this mode of treatment seemed significant in the case of advanced cancer. However, radiotherapy resulted in increased digestive disturbances, mainly in rectal damage, and necrosis of subcutaneous tissue. Dose analysis for intracavitary irradiation with radium indicated a close correlation between the 5-yr cure rate and the radium dose. From dose calculation points proposed by Todd and Meredish, it was found that intracavitary irradiation with standard radium of 6210 mgh at the Cancer Institute Hospital gave a dose of 5057 R (73.3 R/hr) at point A and 1331 R (19.3 R/hr) at point B. Paraconnective tissue (pelvic end) dose was analyzed in 47 cases. In the case of radium alone, the dose was distributed from 800 to 4,800 R, the average dose being 2,050 R. Radium combined with 4,600 R of telecobalt gave a dose of 5,400 to 9,400 R, with an average of 6,650 R. Lymphograms were used to standardize the range of external irradiation and to individualize the aiming of the irradiation field in paralleled opposing irradiation. The possibility for individualized treatment, rather than uniform treatment, was proved by dose calculations and individualized aiming of the irradiated field. (Japan)

58071 TANGENTIAL PENDULAR COBALT THERAPY IN THE MANAGEMENT OF BREAST CANCER. Magno, L. (Spedali Civili, Brescia, Italy). Radiol. Med.; 56: No. 11, 1060-6 (Nov 1970). (In Italian).

A technique known as tangential pendular ^{60}Co γ therapy was used for the postoperative irradiation of the chest wall and internal mammary lymph nodes following mastectomy. A group of 469 patients was treated in this way following the resection of breast tumors, often of unknown clinical stage. The great majority of the series presented histologically demonstrable axillary metastases. Assessment of the survival rates showed overall values of 74% and 58% for 3 and 5 year survivals respectively. Recurrences were observed in 54 patients (11.5%), 28 of whom died within one year. Most recurrences appeared within one year of surgery. Doses of up to 4500 rad were employed without complications. (auth)

58072 TUMOR-HOST RELATION IN CANCER RADIOTHERAPY. Oboshi, Shoichi (National Cancer Center, Tokyo). Gan No Rinsho; 16: No. 6, 651-7(Jun 1970). (In Japanese).

The basis for the effect of radiotherapy on cancer tissues is the lethal effect of radiation on cancer cells. Cancer cells destroyed by irradiation all undergo autolysis and disappear. Therapeutic effects on various cancer tissues, such as malignant lymphoma, undifferentiated carcinoma, squamous epithelial carcinoma, adenocarcinoma, and cancer tissues having necrotic foci, are slightly different but are fundamentally the same, the process being autolysis of individual cancer cells. It was revealed in radiotherapy of human cancer that the antitumor immune mechanism of the host plays an important part in addition to the lethal effect of radiation on cancer cells. Irradiation of tumor tissue results in the swelling, degeneration, and lytic disappearance of tumor cells, and numerous lymphocytic cells infiltrate between tumor cells attaching to them. This corresponds to rejection in homologous transplantation of normal or cancer tissue. Consequently, this reaction is considered to be related to the cell immunity of the host against cancer tissue, and transplantation experiments to prove this phenomenon were carried out in Donryu rats. In the actual treatment of human cancer, it is important not to injure this ability of the host for immune reaction, and to strengthen this ability by some means, although there still remains a doubtful point in this theory. (Japan)

58073 METHODS, TECHNIQUE, AND CLINICAL RESULTS WITH PREOPERATIVE RADIOTHERAPY IN 487 CASES OF BREAST CANCER. Malaspina, A. (Ospedale Maggiore, Novara, Italy). Radiol. Med.; 56: No. 11, 1055-9(Nov 1970). (In Italian).

A group of 487 patients with breast cancer in Steinthal's first three stages received preoperative conventional x and ^{60}Co γ radiotherapy. The following survival rates were observed: Stages I and II: 5 yr, 58%; 10 yr, 42%; 15 yr, 35%; Stage III: 5 yr, 26%; 10 yr, 13%; 15 yr, 2 out of 12 cases. The survival rate was much the same with the two techniques, though local and general reactions were less extensive with γ therapy. (auth)

58074 RESIDUAL LESIONS FOLLOWING EXTERNAL HIGH ENERGY RADIATION THERAPY. Kakehi, Masae; Mori, Tomoyuki; Yamashita, Nobuo; Kitagawa, Toshio (Aichi Cancer Center, Nagoya, Japan). Nippon Igaku Hoshasen Gakkai Zasshi; 30: No. 3, 296-301(Jun 1970). (In Japanese).

At the end of the course of high energy treatment of cervix uteri, there were still clinically detectable residual tumors in the irradiated area sometimes, even after a sufficient radiation dose was given. Diagnostic procedures and treatment of the residual disease were discussed resulting in the external irradiation of carcinoma of the cervix uteri in the second and third stages on two different high energy units. One hundred and fifty one cases were treated with ^{60}Co γ ray and with 6 MV x ray. Results showed that 38.4% of the cases had residual lesions including true remnant and 13.2% of the cases had true remnant at the end of the course of the external treatment. It is quite important to observe the radiation response of the irradiated lesion for at least 1.5 months for ^{60}Co and three months for 6 MV x ray after the completion of radiation treatment to detect true remnant. Additional radiation treatments were given to the residual lesions with small source irradiation in most of the cases when they were determined to be true remnant. Most of the detectable lesions were well localized at the surface of the cervix. True remnant was controlled well with 64.3% of curability. This result suggested the possibility of a radical cure of true remnant with small source irradiation and the clinical value of the small source technique was reevaluated. (Japan)

58075 TECHNICAL PROBLEMS IN THE HIGH ENERGY ELECTRON BEAM THERAPY. Mitsuta, Hideo (Osaka City Univ.). Nippon Hoshasen Gijutsu Gakkai Zasshi; 26: No. 4, 1-22(Mar 1971). (In Japanese).

The results of experimental studies on the following problems in high-energy electron beam therapy were reported: measurements of the outputs and doses—problems in conducting the measurements on the ionization type dosemeters were examined along with other dosimetry problems. Measurements of the energy—the practical range method and the radioactivating method were studied. The fabrication of simple energy checkers that utilize magnets and their applications were described. As the subject of study in regard to the dose distribution, the relations of the dose distribution to such factors as energy, scatterer, area of radiation field, and the material and shape of the treatment cone were scrutinized. Attempts were made to improve the dose distribution. Several approaches were made with the aim of extending as much as possible the range of the therapeutic capacity of the accelerators with definite upper limits on energy. The principal aims of these attempts were to increase the depth dose, and particularly, to give an effective radiation to small focus. (auth)

58076 CLINICAL AND TECHNICAL OBSERVATIONS IN THERAPY WITH 42 MeV BETATRON. Di Guglielmo, L.; Coucourde, F.; Jucker, C.; Rovera, S.; Maestro, A.; Casolo, F. (Univ., Pavia, Italy). Electromedica; No. 4, 104-10(1969).

Radiotherapy techniques used on 1028 patients treated with a 42 MeV Betatron over a three year period are described. Early results using high-energy electrons and x radiation, either separately or in combination, for the treatment of a wide variety of neoplasms are reported. (C.H.)

58077 COMMENTS ON MORBIDITY IN PRESENT-DAY RADIOTHERAPY. Kagan, A. Robert (Cedars-Sinai Medical Center, Los Angeles). Radiol. Clin. Biol.; 40: No. 4, 221-9(1971).

The relationship of biological effects in normal tissues to dose fraction factors in radiotherapy of neoplasms using supervoltage radiations is discussed. It is pointed out that the advent of supervoltage irradiation techniques has resulted in the irradiation of larger volumes of normal tissues, more intense daily radiation doses being given, and the administration of larger total radiation doses over short periods of time, and that since the area of maximum ionization is below the skin the skin reactions can no longer be used as an indication of injury of normal tissues. The additive effects of irradiation and antineoplastic drugs on hematopoietic tissues are considered. It is concluded that a radiation dose of 1,000 rad/week delivered to large tissue volumes results in injury to normal tissues and that combined chemotherapy and irradiation results in additive injury to normal tissues. (C.H.)

58078 REAL TIME DOSE DISTRIBUTION DISPLAY BY DIGITAL COMPUTER. Inamura, Kiyonari (Nippon Electric Co. Ltd., Tokyo); Otani, Shiro; Umegaki, Yoichiro; Mototake, Sakudo; Amari, Hiroko. Nippon Igaku Hoshasen Gakkai Zasshi; 30: No. 4, 315-33(Jul 1970).

The convenience of this system is to determine the optimum irradiation for each patient, by getting the figure of absorbed dose inside the body from the isodose curve, immediately after it has obtained the conditions indicated directly and easily by radiotherapists. Moreover recording of practical treatment can be performed automatically by this system. The isodose curve is obtained in about four seconds when irradiation from one port is set, and in about fifty-seven seconds by irradiation from ten ports. This system is composed of the Central Processor of NEAC-3100 Clinical Digital Computer System, Specific Input Unit and CRT Display Unit which has been specially projected, XY recorder and the other related units. The doses are calculated on the 2.5 mm interval sampling mesh points. Arbitrary isodose curves and maximum doses are displayed. (Japan)

58079 ENVIRONMENTAL CONTAMINATION WITH ^{131}I RELATED TO THE TREATMENT OF HYPERTHYROIDISM AND CARCINOMA OF THE THYROID GLAND. Blum, Manfred; Chandra, Ramesh; Marshall, Christopher H. (New York Univ., N. Y.). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 57-9(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

The possibility of contamination of the environment by ^{131}I excreted by patients during interstitial treatment of hyperthyroidism or thyroid carcinoma was investigated. The excretion patterns of ^{131}I (urine, feces, saliva, sweat) were examined for the possibility of contamination of the air, linens, sewage, dishes, and surfaces. It is assumed that patients are hospitalized and placed in isolation until the radioactivity has decreased. In the case of outpatients discharged with 30 mCi or less radioactivity a reasonable limit for the exposure of relatives would be the ICRP recommendation of maximum exposure of 3 rems/yr. (C.H.)

58080 EFFECT OF IONIZING RADIATION ON MITOTIC ACTIVITY OF CULTURED CELLS. Khamidov, D. Kh.; Khakimov, P. A.; Kolesnikova, S. S.; Mamataliev, U. (Inst. of Biochemistry, Tashkent). Uzb. Biol. Zh.; No. 2, 10-12(1971). (In Russian).

The influence of comparatively small doses of gamma radiation on the mitotic activity of human cancer cells under culture conditions was investigated. Gamma radiation doses employed were: 25, 50, 100, 300, 600 R and 3 kR, following which colchicine was added and an incubation period of 2 to 3 hr at 37°C. The radiation treatment accelerated the mitotic activity of the cells; 44% or 28% as compared with controls, depending upon the type of cells used. (K.S.W.)

58081 REPAIR OF POTENTIALLY-LETHAL RADIATION DAMAGE IN MAMMALIAN CELLS: ENHANCEMENT BY CONDITIONED MEDIUM FROM STATIONARY CULTURES. Little, J. B. (Harvard Univ., Boston). Int. J. Radiat. Biol.; 20: No. 1, 87-92(1971).

Cultures of Chang human-liver cells and Chinese hamster cells (V-79) were x-irradiated during the stationary phase at a dose rate of 100 R/min at room temperature. Survival curves are presented for cells from stationary-phase cultures exposed to trypsin and sub-cultured 0, 6, and 12 hrs after irradiation and for exponentially growing cells incubated for 6 hrs after irradiation with conditioned media from stationary cultures. Cultures of exponentially growing cells were also incubated for 6 hrs after irradiation with a 50-50 mixture of fresh and conditioned media and ultimate survival compared with that in cultures incubated with either medium. In 11 experiments in which cultures of liver cells were given single doses of 800 to 1600 R, the survival of cells incubated with the 50-50 mixture was variable, but consistently greater than that of control cells and generally approaching that of cells incubated with conditioned media. The activity was destroyed by incubation for 1 hr at 56°C but insensitive to DNA-ase and RNA-ase. Results suggested that Chang liver cells release a diffusible substance into the medium promoting the repair of potentially lethal radiation damage. Experiments with Chinese hamster cells exposed to 2000 R, where survival was only slightly enhanced by post irradiation incubation in a mixed medium, suggested that medium depletion may have been a significant factor. (UK)

58082 GROWTH INHIBITION AND RADIOSENSITIZATION OF 5-FLUOROURACIL IN CULTURE OF HeLa CELLS. Moriki, Toshio (Mie Prefectural Univ., Tsu, Japan). Mie Med. J.; 19: No. 3, 263-75(Jan 1970).

Cytological and radiobiological properties of HeLa cells after treatment with 5-fluorouracil (5FU) are described. Treatment with 5FU inhibited cell growth at doses of more than 0.5 μg/ml, even at 5 μg/ml for 30 min. Treatment at 5 μg/ml for 24 hrs reduced the mitotic index, and after removal of the drug, induced a peak in the mitotic index of 7% 24 hrs later. The formation of polynuclear cells of 45% occurred 48 hrs later. The drug caused the cells to accumulate at the S phase by the incomplete inhibition of DNA synthesis without affecting the other mitotic processes during the treatment. After removal of the drug, the blocked cells entered into the G_2 phase and were blocked again at the S stage. The radiosensitizing effect of the inhibitory action on cell growth was found during the combined treatment of the cells with 0.05 μc/ml 5FU for 24 hrs followed by exposure to 35 ergs/mm^2 of uv radiation. Unscheduled DNA synthesis was enhanced by at least a factor of 2 by treatment with 5 μg/ml 5FU for 24 hrs in combination with 70 ergs/mm^2 of uv irradiation. Unscheduled DNA synthesis was further enhanced by partial irradiation with an uv microbeam of one-half of the nuclear component. The rate of DNA synthesis was dependent upon the dose of 5FU, and was virtually independent of the dose of uv light. (auth)

58083 EXPERIMENTAL STUDY OF THE EFFECTS OF X RAYS AND ELECTRONS ON MALIGNANT TUMORS. Hasegawa, Susumu (Tokyo Medical Coll.). Tokyo Ika Daigaku Zasshi; 27: No. 6, 811-32(Nov 1969). (In Japanese).

The effects of x-ray and electron beams on Takizawa's sarcoma and Yoshida's sarcoma were investigated in vivo, and observations were made on the transplantation rates and the growth-rate of the tumors. Irradiated Takizawa's sarcomas developed at the lateral, femoral, and subcutaneous regions of mice were extracted and transplanted to those regions of other healthy mice. When the size of the grown tumor was more than 25 mm^2, the tumor was regarded as a positive transplantation. X-ray administration was made in doses of 1000 to 3000 R under an x-ray voltage of 150 kVp, while betatron was administered in doses of 801 to 2883 rads at 26 MeV, each a single and total irradiation dose. Positive transplantation was observed in 100% of the cases at doses up to 1500 R, in 60 to 85% at 2000 R, in 45 to 50% at 2500 R, and in 0% at 3000 R. In the case of electron beam irradiation, positive transplantation was observed in 100% of the cases at doses up to 1602 rads, in 95 to 100% at 2002 rads, in 70 to 80% at 2403 rads, and in 0% at 2883 rads. The size of the tumor was 179 mm^2 on an average in the 2nd week in the 1000 R irradiation group. When comparing this group as 100% with other groups, the 1500 R group showed 77% and the 2500 R group showed 37%. In rats with Yoshida's sarcoma, the x irradiation group showed a 100% positive rate of transplantation up to 2000 R and 30% at 3000 R. In the cases of betatron irradiation, the positive transplantation rate was 100% up to 1602 rads, 80% at 2403 rads, and 0% at 3204 rads. The size of the tumor was 170 mm^2 on an average by the 10th day in the 1000 R x irradiation group. When this group as 100% was compared with other groups, the 2000 R group showed 85% and the 3000 R group showed 44%. The cases of electron beam irradiation showed nearly similar results to those of x irradiation. (auth)

58084 MECHANISM OF INTERPHASIC DEATH IN RADIATION DAMAGE. PHOTOREACTION FOLLOWING ULTRAVIOLET MICROBEAM IRRADIATION AT A NUCLEAR AND CYTOPLASMIC PART OF LIVING CELLS. Karitani, Yoshiaki (Mie Prefectural Univ., Tsu, Japan). Mie Med. J.; 19: No. 3, 277-94(Jan 1970).

The nuclear or cytoplasmic portion was exposed, mainly to a uv microbeam of 2 μ square, in cultured HeLa cells and in vitro human blood leukocytes and newt peritoneal macrophages and some radiocytological properties were observed. Morphological photoreactions in the irradiated nuclei were divided into two types. One type was typically demonstrated in HeLa cells. The irradiated portion was seen as a dark area by dark phase optics, where DNA and basic protein aggregated, and the typical case was seen in newt cells and human blood leukocytes, where the irradiation induced a pale area at low doses, but produced a dark core in its center at high doses. The latter core showed a positive reaction for basic protein by toluidine blue staining at pH 6.0, but was negative in uv absorption. Interphasic death was much more frequently induced by the partial irradiation of the nucleus than by irradiation of the cytoplasm. The irradiated lysosomes in the Golgi area did not show any significant change in dark phase microscopy and acid phosphatase staining, even following partial irradiation with a 15 μ microbeam spot at high doses. In HeLa cells vitally stained with neutral red (3 × 10^4), the irradiated lysosomes shed the dye into the medium in a short time or immediately after irradiation. Thereafter, the decoloration spread widely to all lysosomes and the cells were rapidly killed. Corresponding to the decoloring part of the lysosomes in a vital state, a non-, weak, or diffuse staining part appeared in the acid phosphatase stain of the lysosomes. Mechanisms of interphasic death induced by partial irradiation of the nucleus and in the vitally stained cytoplasm are discussed. (auth)

58085 ELECTRON MICROSCOPIC STUDY OF RADIATION EFFECTS ON CULTURED CELLS WITH DIFFERENT RADIOSENSITIVITIES. Kasuga, Tsutomu; Furuse, Tekeshi; Tsuchiya, Eiko; Takahashi, Ichi (National Inst. of Radiological Sciences, Chiba, Japan). Gan No Rinsho; 16: No. 6, 639-50(Jun 1970). (In Japanese).

Radiosensitivity of cells can be determined from the colony-forming rate, i.e., plating efficiency. In addition, damage to the constitutional elements of cytoplasm is expected to become a factor that controls radiosensitivity of a cell, as well as its mitotic death. Using such hypotheses, comparative examinations were made on two radiation resistant cell cultures showing different reactions to radiation, using melanoma strain B-16XI (isolated from a transplantable mouse melanoma) ($n = 6.5$, $D_q = 285$ R) and HeLa S3 strain ($n = 2.7$, $D_q = 140$ R, $D_0 = 150$ R), based on electron microscopic and histochemical (acid phosphatase reaction) observations. The radiation source was 200 kV, 20 mV x-ray, giving a single irradiation of 1000 R from a distance of 50 cm, the dose rate being 100 R/min, and half-value layer of 0.3 mm Cu + 1.0 mm Al. The most marked differences between these two strains of cells were confirmed by degeneration of mitochondria in irradiated HeLa S3 cells, accompanied by periodical increase of autophagosomes and their behavior, and by the behavior of markedly increased pinocytotic vesicles and microvesicles in irradiated melanoma cells. The present results suggest that the difference in radiosensitivity between HeLa S3 cells and melanoma cells is probably correlated to the difference in all the metabolic functions and activities possessed by the two strains of cells. (Japan)

58086 DEATH OF CULTURED MAMMALIAN CELLS FROM TRITIUM DECAY. SUICIDE EXPERIMENT. Okada, Shigefumi (Tokyo Univ.). Radioisotopes (Tokyo); 19: No. 12, 614-21 (Dec 1970). (In Japanese).

Experiments on the effects of beta decay of tritium on cultured mammalian cells were conducted for studies on the mechanism of cell death. A concentration of less than 2 μCi/ml of tritiated thymidine was administered to cell cultures for more than 10 hr. With one-cycle labeling, only the single strand of DNA was labeled (unifilar labeling) and both strands were labeled (bifilar labeling) when the cells were in contact for more than four cycles. In order to obtain a uniform rate of incorporation of tritiated thymidine into newly synthesized DNA, 10^{-4}M thymidine and 10^{-5}M deoxythymidine were added to the culture medium. The efficiency of beta decay of one tritium atom for killing a cell was 0.006 in unifilar labeled cells and 0.0125 in bifilar labeled cells. The survival curve of unifilar labeled cells was exponential whereas that of bifilar labeled cells was sigmoidal. The beta dose to a nucleus of 3μ radius was calculated to be 0.5 rad per decay. The beta dose corresponding to D_{37} (175 decays/cell) was ca 90 rads in unifilar labeled cells and about 40 rads in bifilar labeled cells. It was concluded that much DNA damage was required to kill the cell and that transmutation of tritium to helium-3 by liberation of beta particles and movement of the ^{3}He nucleus by recoil also played an important role in the death of a cell. (Japan)

58087 COMPARATIVE EFFECT OF HYDROCORTISONE AND CYCLIC AMP ON THE MULTIPLICATION OF CULTURED CELLS (KB STEM) AND THEIR SURVIVAL AFTER ULTRAVIOLET IRRADIATION. Aujard, Colette (Centre National de la Recherche Scientifique, Villejuif, France). Compt. Rend., Ser. D; 272: No. 26, 3340-3(28 Jun 1971). (In French).

It is shown that cyclic AMP inhibits the multiplication of KB cells, as does hydrocortisone, but that in contrast to the hormone, this substance does not favor the survival of KB cells subjected to an aggression such as ultraviolet irradiation. (France)

58088 INFLUENCE OF RECOVERY FROM SUBLETHAL DAMAGE ON THE RESPONSE OF CELLS TO PROTRACTED IRRADIATION AT LOW DOSE-RATE. Fox, Margaret; Nias, A. H. W. (Christie Hospital and Holt Radium Inst., Manchester, Eng.). Curr. Top. Radiat. Res.; 7: No. 1, 71-103 (Sep 1970).

The nature of physical and chemical factors affecting recovery from sublethal damage in mammalian cells is discussed and evidence presented to show that it is not correlated with repair replication. Reduction of dose-rate to a biological system results in reduced cell killing; such effects are described and the influence of environmental factors discussed. In most mammalian systems previously described analysis of the contribution of recovery from sublethal damage is complicated by continued cell proliferation. It is suggested that irradiation of cells at low dose-rates at room temperature can provide a clearer picture provided that plating efficiencies remain high. At dose-rates of 30 to 40 rad per hour there is a decreasing proportion of survivors in the population. If dose-rates are reduced to about 10 rad per hour, then a steady state situation can be achieved where death rate per cell cycle does not exceed birth-rate, and the population will survive indefinitely. The kinetics of this situation are discussed. The width of the shoulder on the acute dose response curve is a good indication of the sensitivity of a cell line to low dose-rate irradiation and it is suggested that the maximum dose tolerated per cycle in steady state is a good indication of the efficiency of the repair system for sublethal damage. (auth)

58089 DAMAGE AND REPAIR PROCESSES RELATIVE TO NEUTRON (AND CHARGED PARTICLE) IRRADIATION. Elkind, M. M. (Brookhaven National Lab., Upton, N. Y.). Curr. Top. Radiat. Res.; 7: No. 1, 1-44(Sep 1970).

Of the high linear energy transfer radiations of practical import, fast neutrons are currently receiving considerable attention. This stems mainly from their potential usefulness in connection with the treatment of tumors in view of the reduced oxygen effect associated with high linear energy transfer radiations. However, interest in the radiobiology of fast neutrons as well as charged particle beams derives also from the expected growth of atomic power and a need to understand the hazards to man during flights in space. Repair processes are now recognized to have a major bearing on the degree of radiation damage expressed and therefore the dependence of the effectiveness of such processes on radiation quality must be understood. In this review, the dependence of sublethal damage repair is examined to the extent that available data permit. Starting with x rays, for which the data are extensive, fractionation experiments performed with charged particle as well as fast neutron beams are examined in order to help develop a general appraisal of the dependence of repair on the rate of linear energy transfer. While the experiments analyzed refer exclusively to mammalian cells, because of the limited data available with any one cell system, and in order to identify generalities, results from a variety of sources are reviewed. Finally, some initial data relative to the damage to DNA produced by 14 MeV neutrons are also considered relative to the possibility that the targets sensitive to densely ionizing radiation may not be the same as those sensitive to radiation like x or γ rays. 58090 RADIOSENSITIVITY OF GERMINAL AND SOMATIC CELLS OF THE HERMAPHRODITE GONAD OF ASTERINA GIBBOSA PENN FOLLOWING X IRRADIATION. ULTRASTRUCTURAL STUDY OF DIFFERENTIAL RADIOLESIONS. Brusle, Jacques (Faculte des Sciences, Orleans, France. Faculte des Sciences, Orsay, France). Arch. Biol. (Liege); 80: 451-70 (1970). (In French).

X irradiation of hermaphrodite gonads of Asterina gibbosa confirmed the existence of two germinal strains, whose differential radiosensitivity was clearly distinct. The spermatogenic lineage was more fragile than the ovogenetic one; with equal irradiation doses, spermatogonic and spermatocytic radiolesions appeared earlier and were more intense than those of ovogonies and ovocytes. The results of x irradiation did not yet allow the assumption that the differential threshold of alterations and behavior exists from the very first stages of cell differentiation within each lineage. With the doses tested, no other difference of sensitivity was detected, which might imply the existence of undifferentiated cells or gonies. The sole radioresistant somatic cells observed in the gonads was the follicular and phagocytic cells. The germinal epithelium was definitely lacking. (auth)

58091 ACTINOMYCIN D: ITS DUAL ROLE IN RADIOPROTECTION AND RADIOSENSITIZATION TO GAMMA RADIATION IN TETRAHYMENA. Mossman, K. L.; Whitson, G. L. (Univ. of Tennessee, Knoxville). Radiat. Eff.; 10: No. 1-2, 9-15(Jul 1971).

Log phase cells of Tetrahymena pyriformis, HSM, were exposed to various combinations of Actinomycin D and γ radiation. At low concentrations, Actinomycin D acted as a protective agent to ionizing radiation, whereas at high concentrations this drug sensitized cells to γ rays. Analysis of growth curves indicated that delays in growth in log phase cultures were obtained after cells were first pretreated with Actinomycin D (15 μg/ml) and then exposed to 80,000 rads of γ rays. At low concentrations, Actinomycin D (2 μg/ml) produced no growth delays in cells exposed to the same dose of γ rays. Studies on the rate of RNA synthesis in log phase cells treated with Actinomycin D indicated that at low concentrations little, if any, RNA synthesis was inhibited, whereas a decrease in RNA synthesis was observed at the high concentrations of this same drug. Further studies on the stability of total cellular RNA, when synthesis was depressed by Actinomycin D, indicated that very little degradation of this nu-

XU

cleic acid occurred following large doses of ionizing radiation. On the other hand, the stability of DNA in cells was affected in cells exposed to ionizing radiation and in cells pretreated with Actinomycin D and then exposed to ionizing radiation. Ionizing radiation, alone, resulted in some breakdown of DNA and cells pretreated with Actinomycin D (20 μg/ml) resulted in more degradation of DNA. (auth)

58092 INFESTATION OF IRRADIATED WHITE OAKS BY THE SOLITARY OAK LEAFMINER, CAMERARIA HAMADRYADELLA (LEPIDOPTERA: GRACILARIIDAE). **Hinckley, A. Dexter (Brookhaven National Lab., Upton, N. Y.). Ann. Entomol. Soc. Amer.; 64: No. 5, 1094-8(15 Sep 1971).**

On isolated shoots of white oak exposed to 20–30 roentgens per day in 2 gradients of gamma irradiation, solitary oak leafminer, Cameraria hamadryadella (Clemens) (Lepidoptera: Gracilariidae), densities (sample means for 2nd-generation mines per 100 leaves and standard errors of the means) were 220 ± 33 in 1967, 167 ± 67 in 1968, and 16 ± 4 in 1969. During the same years, on white oaks exposed to less than 3 roentgens per day, the densities were 48 ± 7, 35 ± 5, and 3.8 ± 1.7 for leaves on branches 1–3 m high and 20 ± 2, 9.1 ± 1.1, and 1.0 ± 0.2 for leaves collected on the ground. 58093 HISTOPATHOLOGICAL STUDIES ON IRRADIATED AND CHEMOSTERILIZED BEET LEAFHOPPERS, CIRCULIFER TENELLUS. **Ameresekere, R. V. W. E.; Georghiou, G. P.; Sevacherian, V. (Univ. of California, Riverside). Ann. Entomol. Soc. Amer.; 64: No. 5, 1025-31(15 Sep 1971).**

The internal morphology of the reproductive system of Circulifer tenellus (Baker) is described. Morphological, as well as histological, changes resulting from exposure of nymphs and adult males and females to ^{60}Co irradiation, or treatment by N,N′-hexamethylenebis(1-aziridinecarboxamide) are discussed. Primary egg chambers with developing oögonia, oöcytes, and follicle cells are present in 12-hour-old females. Females exposed to 5 kr irradiation showed only a reduction of various cell stages of oögenesis, but 10 kr dosages caused nuclear disintegration and cellular atrophy. Similar effects were observed in chemosterilized individuals, nymphs being more sensitive than adults. Treatment of males with 20-kr dosages resulted in pronounced cell necrosis and sperm depletion. (auth)

58094 RESTORATION EFFECT OF ECDYSONE AFTER THE ARRESTING OF POST-EMBRYONIC DEVELOPMENT OF γ-IRRADIATED CERATITIS CAPITATA WIED LARVAE (TRYPETIDAE DIPTERONS). **Çals-Usciati, Josette (Univ., Paris). Compt. Rend., Ser. D; 272: No. 26, 3295-8(28 Jun 1971). (In French).**

The re-establishment of the formation of puparia by injecting ecdysone into the permanent larvae, obtained by γ radiation, established the radiorestoration action of ecdysone. (France)

58095 EFFECT OF X IRRADIATION OF THE HEAD ON NEUROSECRETORY CELLS IN GRYLLUS DOMESTICUS L. **Theodorescu, M. (Bucharest Univ.); Novak, V. J. A. Acta Entomol. Bohemoslov.; 67: No. 4, 207-10(1970). (In French).**

The head of the last instar nymphs was irradiated 1 and 4 days after moulting with doses ranging from 100 to 500,000 R. Paraffine sections of the brain and thoracic ganglia stained with paraldehyde fuschsine were investigated as to the degree of the induced injury. The structural state of the cells, amount of neurosecretion and its disposition in the neurons and axons, and the nucleocytoplasmic relation were ascertained. Only the motility of the insects was affected and distinct morphological changes took place following irradiation with 500,000 R. The state of the neurosecretory cells was compared with that of the average nerve cell. (NSA of Czech)

58096 MORPHOLOGY AND DEVELOPMENT OF THE MACRONUCLEI OF THE CILIATES STYLONYCHIA MYTILUS AND EUPLOTES AEDICULATUS. **Ammermann, Dieter (Univ., Tuebingen, Ger.). Chromosoma; 33: 209-38(1971).**

Some stages of macronuclear anlagen development, known from earlier investigations, were studied in detail. The results are: The giant chromosomes of Stylonychia mytilus are not somatically paired, but are connected end-to-end to form one or a few composite chromosomes. When they later disintegrate, the bands become isolated granules. Spectrophotometric measurements show that during the DNA-poor stage which follows the disintegration of the chromosomes, the macronuclear anlagen of Euplotes have a DNA content of 21 c, while the syncaryotic (deriving from syncarya) and hemicaryotic (deriving from haploid hemicarya) anlagen of Stylonychia have the DNA content of diploid micronuclei. Nevertheless the syncaryotic anlagen of Stylonychia and Euplotes initially develop two nucleoli at the end of this stage, the hemicaryotic anlagen of Stylonychia only one. From this it is concluded that the genes of one giant chromosome band stay together in one granule. Labeled DNA from the giant chromosomes which remains in the anlagen during the DNA-poor stage is distributed approximately equally to the daughter nuclei during the first few fissions of the exconjugants. Autoradiographic experiments showed that the DNA of the macronuclei of Stylonychia that is duplicated at one time in a replication band is not duplicated simultaneously during the next DNA-duplication. The DNA duplications during the second polyploidization stage of the macronuclear anlagen development are exceptions, because the mixing of the macronuclear DNA which occurs before every fission does not occur during the second polyploidization stage. The pseudomicronuclei which sometimes are formed from the macronuclei in emicronucleated strains of Stylonychia contain numerous elements which are much smaller than the chromosomes. The macronucleus of Stylonychia is very insensitive to irradiation with x-rays. The results lead to the following hypothesis: The macronuclei of the two hypotrich ciliates contain unconnected chromomeres or small aggregates which are distributed at random to the two daughter nuclei during the divisions. 58097 (ORNL-tr-2521) TUMORS OF ALBINO RATS OF VARIOUS AGES AFTER SINGLE TOTAL-BODY ROENTGEN IRRADIATION. **Reincke, U.; Stutz, E.; Wegner, G. Translated by R. Gregg Mansfield (Oak Ridge National Lab., Tenn.), from Z. Krebsforsch.; 66: 165-86(1964). 32p. Dep. NTIS.**

Four groups of male and female Wistar rats received a single total-body x irradiation of 270 R, at 5 days before birth and 13, 49, and 121 days after birth. A fifth group consisted of gravid females 121 days old. A sixth group was composed of non-irradiated control animals. The 30 day mortality after prenatal irradiation was 44% and after post-natal irradiation between 0 and 9%. The animals that survived intrauterine irradiation often showed growth retardation, and in over 90% of the autopsies there was microencephaly, usually combined with unilateral or bilateral microphthalmia. In addition, there was hypoplasia of the genital organs of both sexes. In all the irradiated groups the life expectancy was reduced about three to six months. It was not influenced, however, by the age at which they were exposed to irradiation. In 512 irradiated and autopsied animals, 402 benign and malignant tumors were diagnosed histologically. Among the 118 controls 44 tumors were found. In the irradiated males the number of malignant tumors was increased up to 10 times the rate of spontaneous tumors, and in the irradiated females up to four times. The benign tumors in the male animals did not increase after irradiation, however, in the females they were very considerably increased due to the frequency of breast and ovarian tumors. (auth)

58098 EFFECT OF LOW X-RAY DOSES ON THE CENTRAL NERVOUS SYSTEM. RESEARCH FOR TESTING THE ROLE OF DISTANCE AND TO ESTABLISH THE RATIO BETWEEN NEURONAL HISTOPATHOLOGICAL ALTERATIONS AND NUCLEIC ACID HISTOCHEMICAL ALTERATIONS; ACUTE CELLULAR DISEASE-INDUCED NEURONAL ALTERATIONS AND SEVERE CHRONIC CELLULAR DISEASE ALTERATIONS; NEURONAL AND EXTRANEURONAL ALTERATIONS. **Vasculescu, Tr.; Pasculescu, Gh. Oncol. Radiol.; 9: No. 6, 551-60(1970).**

Experiments were performed on 98 rats killed 1, 6, 24, and 48 hrs and 1, 6, and 20 weeks after irradiation of the central nervous system with a single dose of 30 R; 10 R/m; 160 kV; 0.5 Cu + 0.5 Al at 100 cm and 40 cm respectively focal distance from the skin. It was found that radiation injuries increased with distance. A biphasic aspect of neuronal modification dynamics and the causal ratio between RNA cytoplasmic alterations (fall or precipitation) and acute or severe chronic disease-induced histopathological changes were emphasized. Determinations of acid phosphatase enabled one to conclude, simultaneously with the acute cellular disease alterations (fall of cytoplasmic RNA), on an increase of lysosome permeability. Though some of these aspects are apparently significant, yet causal relations between neuronal acute and chronic modifications on the one hand, and neuronal changes, haemodynamic or extraneuronal changes in general, on the other, could not be established. (Rom. Sci. Abstr.)

58099 SPECIFICITY OF INCREASED RESISTANCE OF ANIMALS TO REPEATED ACTION OF RENAL POISONS. **Vaksberg, G. M. Patol. Fiziol. Eksp. Ter.; 14: 31-3(Jul-Aug 1970). (In Russian).**

Rabbits and rats were subjected to repeated and cross poisoning with uranium and mercuric bichloride. Examination of residual nitrogen in the blood demonstrated that increased animal resistance to repeated poisoning occurred only when the same poison (uranium or mercuric bichloride) was administered. Residual blood nitrogen increased after each poisoning, regardless of the order of administration of uranium and mercuric bichloride to the animals. Antigens absent in normal animals were revealed in experiments on guinea pigs (in their kidneys and liver) with the aid of reaction of anaphylaxis with desensitization. (auth)

58100 OPERANT BEHAVIOR OF PRE- AND POST-PUBERTAL RATS IRRADIATED WITH ^{131}I IN THE LAST TRIMESTER OF GESTATION. **Bogdanove, L. H.; Doody, A.; Nadackapadam, X. (Dept. of Pharmacology, Chicago). Experientia; 27: No. 8, 907-8(15 Aug 1971).**

Rats were injected intraperitoneally with iodine-131-labeled sodium iodide on the fourteenth day of gestation. The irradiation induced varying degrees of thyroid destruction in mother and siblings and decreased ratios of iodine labeled protein; inorganic iodine in mothers, compensatory hyperactivity in thyroids of siblings, and increased perseverance of operant behavior which decreased with maturation. Changes observed in siblings were not fully accountable by either differences in labeled iodide thyroid uptake, serum protein binding or thyroid histology. (H.L.W.)

58101 VVEDENSKII'S FREQUENCY PESSIMUM AFTER IRRADIATION OF THE SPINAL CORD. **Semagin, V. N. (Inst. of Higher Nerve Activity and Neurophysiology, Moscow). Dokl. Akad. Nauk SSSR; 197: No. 6, 1452-5(21 Apr 1971). (In Russian).**

Orthodromic responses were recorded from crosscut ventral roots during electrical irritation of the crosscut dorsal roots of the lumbar branch of the spinal cord of 37 non-narcotized rats. Rhythmic irritation proceeded at the intervals: 5, 10, 20, . . ., 100 sec. X-irradiation of the spinal cord was conducted on 28 ambulatory rats at a dose of 1000 R. Mono- and polysynaptic responses of controls and irradiated mice were noted. The results are tabulated and discussed. (K.S.W.)

58102 EFFECT OF X-RAY OR GAMMA-RAY IRRADIATION ON RAT TIBIA. **Murakami, Eisuke (Kyushu Univ., Fukuoka). Kyushu Ketsueki Kenkyu Dokokaishi; 20: No. 2, 159-96(Jun 1970). (In Japanese).**

The effect of x rays (250 kVp, HVL = 1.45 mm Cu) or ^{60}Co gamma rays on the bone and bone marrow of young female rats was studied. Each irradiated group was subdivided into four groups according to dose (1500 R, 3000 R, 5000 R, and 7000 R in a single dose). On roentgenographical observation, the stunting of longitudinal growth of the tibia irradiated with 3000 R of x rays or gamma rays was more prominent than that of the tibia irradiated with 1500 R. Comparing the stunting of longitudinal growth of x-irradiated tibia with that of gamma-irradiated tibia, the former were more prominent than the latter. On microscopic examination of the control group, the mean value of thickness of the proximal growing epiphyseal plate of tibia irradiated with 3000 R or 5000 R of x rays or gamma rays increased gradually. Histopathologically, the epiphyseal plate of tibia that were subjected to 1500 R of x rays or gamma rays revealed degeneration of the columnar cartilage cells at 3 days after irradiation. It regained completely its original hematopoietic activity at 10 days after irradiation. Those irradiated with 5000 R and 7000 R, in a single dose, of x rays or gamma rays became aplastic with edematous changes. Fracture and/or disruption also occurred at 5000 R or 7000 R in both cases during 2 to 12 months. Neoplasms were also seen, e.g. spindle cell sarcoma, osteoplastic osteogenic sarcoma, and squamous cell carcinoma. The extent of injury from x rays to the bone tissue and the growing epiphyseal plate was greater than that from gamma rays, but there was no qualitative difference of biological injuries induced by x rays and gamma rays. (Japan)

58103 PARTICIPATION OF X-RAYED CELLS IN A REGENERATE INDUCED ON AN X-RAYED LIMB OF THE SALAMANDER, TRITURUS VIRIDESCENS. **DeSha, David Lawrence. New Orleans; Tulane Univ. (1971). 78p. University Microfilms Order No. 71-20,218.**

Thesis.

The purpose of the present study was to determine whether or not x-irradiated cells can participate in regeneration. It was necessary to produce labeled x-rayed cells so that their movements could be traced. Labeled, irradiated cells were obtained in the following manner. Tritiated thymidine was injected intraperitoneally into animals with regenerating right forelimbs. Cells in the regenerate which differentiated, and soon ceased to divide, were labeled and remained labeled for long periods. The limb regenerated with labeled tissues subsequently was x-rayed with 2000R, and unirradiated hind limb skin was transplanted to the x-rayed forelimbs to induce regeneration. As controls against spontaneous regeneration, some of the x-rayed limbs with labeled internal tissues merely were amputated. Regenerates were produced on the x-rayed limbs supplied with grafts, and only small nubbins of tissue accumulation were found in the control limbs. These nubbins often regressed. Histological studies of the x-rayed limbs supplied with a graft indicated that labeled x-rayed cells were released from the internal tissues near the amputation surface and were incorporated into the blastema. These cells presumably formed a portion of the differentiated tissues of the regenerate. Studies were performed to verify that the labeled cells observed in the regenerates on the x-rayed limbs were from x-rayed internal tissues and were not from extraneous sources. It can be concluded from this study that 2000R of x-irradiation blocks salamander limb regeneration; that transplantation of unirradiated tissues to the limb can overcome the effects of irradiation; and that x-rayed cells can participate in regeneration of the x-rayed limbs. Thus, it appears that x-irradiation of limbs does not block the ability of some x-rayed cells to contribute to a regenerating system; and therefore, it is not a reliable method of determining which individual tissues or cells contribute to the formation of the blastema. (Diss. Abstr. Int., B)

58104 SERUM CONCENTRATIONS OF THREE IMMUNOGLOBULIN CLASSES IN PIGS AFTER EXPOSURE TO A γ-RAY DOSE OF 1600 RADS. **Bazin, H.; Daburon, F.; Vaerman, J. P.; Heremans, J. F. (Dept of Experimental Medicine, Brussels). Int. J. Radiat. Biol.; 20: No. 1, 93-5(1971).**

Data are presented giving the serum concentration of immunoglobulins IgM, IgA and IgG in 9 pigs, during 6 days after γ-irradiation with doses of 1600 rads. The only significant change was an increase in serum IgA. (UK)

58105 SHORT-TERM KINETIC STUDIES ^{18}F UPTAKE IN NORMAL, X-IRRADIATED, AND FRACTURED BONE. **Lamel, David Arthur. Los Angeles; Univ. of California (1971). 162p. University Microfilms Order No. 71-19,456.**

Thesis.

Previous short-term kinetic studies of "bone-seeking" isotopes concentrated on calcium and strontium. The radioactivity as a function of time curves obtained with an external detector placed over a particular site of interest during the first hour following intravenous injection of a radioactive tracer, were labeled "osteograms". Osteograms obtained with the current isotope used for bone scanning, fluorine-18, had not been investigated. Techniques were developed for obtaining good quality osteograms using fluorine-18. These methods were effective in both controlled, laboratory animal experiments, and in everyday applications in a hospital clinic. Using a large computing system, the osteograms were described in the following mathematical form: $\mathrm{OTS/MIN}(t) = 1 \pm A_1 \cdot e^{\pm B_1 \cdot t} \pm A_2 \cdot e^{\pm B_2 \cdot t} \pm A_3 \cdot e^{\pm B_3 \cdot t}$. Physiological meanings of the three exponential terms were postulated: mixing of the radioactive tracer with the blood, movement of the tracer through the extravascular spaces, and incorporation of the tracer within the crystalline portion of the bone. A series of osteograms of the tibiae of "normal" laboratory rabbits was obtained. In addition, osteograms of the following abnormal conditions were studied: fracture of the tibia, sham fracture of the tibia, x-irradiation of the tibia, and x-irradiation plus fracture of the tibia. While sham fracture osteograms showed no deviations from normal patterns, the fracture osteograms indicated a large increase in the mineralization rate. The effect of 2000 rads of x-irradiation to the tibia was to suppress mineralization, with the result that irradiated fractures would not heal, at least during the ten weeks following fracture. The fracture osteograms, both with and without x-irradiation, exhibited an increased importance of the exponential term associated with tracer movement within the extravascular spaces. Neither the sham fracture osteograms or the x-irradiation osteograms displayed the phenomenon. (Diss. Abstr.)

58106 X-RAY INDUCED INCREASE IN NUMBER OF CYSTEINE-RICH PERIVENTRICULAR GLIAL CELLS IN THE RAT BRAIN. **Srebro, Z. (Inst. of Biomorphology, Krakow). Experientia; 27: No. 8, 945-7(15 Aug 1971).**

X radiation was administered in doses of 1000 to 4000 R to the head region of 58 rats, the remainder of the body being shielded with lead. The animals were killed on the 7th, 14th, or 21st post-irradiation days and the brains examined histologically. Fifty per cent of the animals given 3000 and 4000 R died before the 7th post-irradiation day; the surviving animals of these groups showed considerably higher numbers of the cysteine-rich glial cells in the brains than rats of other groups. The significance of the results is discussed. (H.L.W.)

58107 ACTION OF GAMMA RADIATION ON THE ADRENAL CORTEX AND THYROID GLAND IN THE RAT. **Pegel, V. A.; Dokshina, G. A.; Potapova, A. I. (Science Research Inst. of Biology and Biophysics, Tomsk, USSR). Izv. Sib. Otd. Akad.**

XU

Nauk SSSR, Ser. Biol. Nauk; 3: No. 15, 124-7(Dec 1970). (In Russian).

The effect of high-energy betatron radiation on some endocrine systems on the rat was investigated. White rats of both sexes were subjected to 25 MeV quanta at 50 Rad/min for a total dose of 1000 Rad. Acute radiation sickness developed on the second day, and the animals subsequently lost considerable weight. 11-hydroxycorticosteroids were measured in the blood plasma, and glandular functions were evaluated in the standard manner. Blood leucocytes decreased rapidly in number following irradiation whereas plasma steroid content increased. It was concluded that the effect of radiation was an increase of adrenal cortex activity, and a depression of the thyroid activity. (K.S.W.)

58108 STUDY OF WEIGHT CHANGE OF THE SPLEEN FOLLOWING FRACTIONATED IRRADIATION IN MICE. Yasukochi, Akira (Kyushu Univ., Fukuoka). Fukuoka Igaku Zasshi; 61: No. 6, 359-75(Jun 1970). (In Japanese).

Changes of spleen weight following fractionated whole-body irradiation were studied in mice. Mice were irradiated with 190 kVp x rays and ^{60}Co γ rays in two equal fractionations at 0, 1, 3, 6, and 10 day intervals (zero day interval meant single exposure). The exposure dose that reduced spleen weight was measured on the 4th day after the second irradiation. The exposure dose for fractionation of 3 day intervals was almost equal to that of a single exposure and smaller than that of other groups for 50% reduction of spleen weight. The equal effect ratio of ^{60}Co γ rays to 190 kVp x rays was 0.7 to 0.8 on the basis of the result mentioned above. Mice were exposed to 364 rad γ rays in different types of fractions, (0, 1, 2, 3, 4, and 6 day intervals). Spleen weight showed a fluctuation in groups of 2 and 3 day intervals, reaching the minimum value at 1 to 2 days followed by a slight recovery and then a second phase of decrease of weight at 5 days after the second irradiation. Gradual recovery of spleen weight to that of control followed. In order to elucidate the cause of the bi-phasic change of spleen weight, further experiments were performed. All experimental groups of mice were exposed to 364 rad, but different fractionations were given to each group to check whether the first or second irradiation had the primary effect on the change of spleen weight. All groups showed more or less similar pattern of change of spleen weight, but this pattern was most markedly seen in the groups to which smaller doses were given on the second irradiation, as in the groups of 8 : 2 and 9 : 1 fractionation. Histological studies showed no significant findings to explain this bi-phasic type of change of spleen weight. (auth)

58109 MUTUAL EFFECTS OF SUBLETHAL HEMORRHAGIC SHOCK AND SUBSEQUENT WHOLE-BODY IRRADIATION. Sakurai, Kenji (Jikei Univ., Tokyo). Tokyo Jikeikai Ika Daigaku Zasshi; 85: No. 3, 299-313(May 1970). (In Japanese).

Suppression or blocking of the reticuloendothelial and pituitary-adrenocortical systems is shown to lower the tolerance against subsequent stress by increasing susceptibility. The current study was directed and aimed to clarify duration and extent of this increased susceptibility, induced by the sublethal hemorrhagic shock, to subsequent stress, namely to whole-body irradiation. Female Swiss Albino mice were subjected to hemorrhage. Critical bleeding volume was determined from a dose-response curve and Berkson's Logit method. Similarly, length of survival and mortality rates of the mice at various doses of whole-body irradiation were calculated. Then the mice were exposed to sublethal hemorrhagic shock (3.1% body weight) followed by supralethal (1000 R) or sublethal (400 R) irradiation in different intervals, 3 hrs, 24 hrs, and 8 days. The mortalities and the length of survivals were analyzed. Only the group of mice subjected to the 1000 R irradiation 3 hrs following the shock succumbed earlier than the control. The results indicated that the shocked mice were susceptible to the subsequent irradiation only if the adverse effects of irradiation took place early enough to be added to the changes ellicited by the sublethal shock. However, recovery from the shock was prompt. In general, by the time when the irradiation changes took place, the animals recovered from any adverse effects of the shock. There was no such mutual enhancement or potentiation by two sublethal stressors observed in mortalities. At any rate, the effects of the sublethal hemorrhagic shock influencing susceptibility to the subsequent stress appeared to be short lived. Probable roles of the RES and the pituitary-adrenocortical systems during exposure to the stresses were speculated. (auth)

58110 RADIATION PROTECTION STUDIES IN ADULT, WEANLING, AND NEONATAL MICE. Rauchwerger, Joel M. Philadelphia; Temple Univ. (1971). 103p. University Microfilms Order No. 71-19,964.

Thesis.

It has been suggested that the radiosensitivity to acute whole-body X-irradiation (LD/50 for 30 days) varies with age in mice, adults and neonates being relatively radioresistant compared to weanlings. Furthermore, it has been shown that the capacity to be protected against hemopoietic death decreases as the age of the mouse decreases from adult to weanling. Thus, it was of interest to determine whether the capacity of the neonate to be protected against hemopoietic death varies with the radiosensitivity, or directly with the age of the mouse. Survival data are presented for both unshielded and tibial shielded C3H/C57bl mice. Results show that neonates can be protected as well as adults i.e., in both the protective factor or "dose reduction factor" (DRF) was approximately 1.7. However weanlings, which have the highest absolute radiosensitivity, cannot be protected as well (i.e., DRF approximately 1.4). Since the basic cause of death following irradiation in the LD/50 range is known to be due to hemopoietic failure, and since all age groups were protected against hemopoietic death to variable extents, the survival data were correlated with the hematological findings in all three age groups for: (a) irradiated-no shield, (b) irradiated-tibial shield, and (c) non-irradiated controls. The hematological studies included: (a) peripheral blood counts (red blood cell, reticulocyte, white blood cell, platelet, and hematocrit), (b) bone marrow cellularity (nucleated cell count) and (c) spleen evaluation, (splenic weight, and histologic sections). Regardless of the age group, a striking similarity was observed in the hemopoietic response following radiation exposures of equivalent lethality. Unshielded mice of all ages died from what is commonly termed hemopoietic death. However, evidence indicates that the hemopoietic systems in different age groups might have differing radiosensitivities, since at different absolute exposures (although equivalent lethalities), there was a similarity of response in both decline and recovery of hemopoietic parameters in shielded mice. On this basis the hemopoietic system of weanlings is the most radiosensitive since they received the lowest exposure. The basis for the poor weanling protectability was found to be correlated with an increased radiosensitivity of the gastrointestinal system. Weanlings exhibited 3 to 6 day "gut death" at X-ray exposures that were closer to their hematopoietic LD/50 than either adults or neonates. (Diss. Abstr.)

58111 REGENERATION OF INTESTINAL MUCOSA AFTER IRRADIATION. Withers, H. R. (Univ. of Texas, Houston). Cancer; 28: No. 1, 75-81(Jul 1971).

From first national conference on cancer of the colon and rectum; San Diego, Calif. (7 Jan 1971). See CONF-710115.

Data are presented on the time-course of regeneration of proliferative (clonogenic) cells of the intestinal mucosa of mice following radiation injury. The changes in the cell loss pattern were correlated with the histologic appearance of the irradiated intestine. In the investigations of jejunal response, a dose of 660 rads of x rays was delivered to the whole abdomen. This reduced cellular survival in the crypts to about 5% of normal. In the experiments on colonic mucosa, the dose of γ rays was 700 rads, which is roughly equivalent to 600 rads of x rays. (auth)

58112 PATHOLOGIC CHANGES IN THE ULTRASTRUCTURE OF HEPATOCYTES IN THE AXOLOTL (AMBYSTOMA TIGRINUM GREEN) UNDER THE INFLUENCE OF ROENTGEN RAYS. Turska, Ryszarda (School of Agriculture, Wroclaw). Acta Med. Pol.; 12: No. 2, 231-3(1971).

From fourth conference of electron microscopy; Lublin, Poland (26 Nov 1969). See CONF-691138.

Adult salamanders (Ambystoma tigrinum) were exposed to a single dose of 1200 R x radiation and killed one hour later. Changes in the ultrastructure of liver cells induced by irradiation are described. (C.H.)

58113 INFLUENCE OF UV RADIATION ON SOME PHYSICO-CHEMICAL PROPERTIES, BIOCHEMICAL PARAMETERS, AND SUBMICROSCOPIC STRUCTURE OF PIGEON ERYTHROCYTES IN VITRO. Andrzej, Ignacy; Klynczak, Joanna Alina; Sysa, Andrzej; Kwiatkowski, Bartlomiej; Sysa, Jozef (Military Medical Academy, Lodz, Poland). Acta Med. Pol.; 12: No. 2, 292-7 (1971).

From fourth conference of electron microscopy; Lublin, Poland (26 Nov 1969). See CONF-691138.

Pigeon blood in vitro was exposed to uv radiation with emission of 4.33×10^8 erg/sec for periods of 5 hours. The following examinations were made: determination of sensitivity/resistance of erythrocytes in hypotonic NaCl solutions; degree of reversion of hemolysis; changes in erythrocytic volume; content of Na$^+$ and K$^+$ in the plasma, blood, and erythrocytes; levels of some of the phosphate esters (ADP, ATP, and AXP) involved in energetic exchange in cells; and acetylcholinesterase activity in erythrocytes. The fine structure of the erythrocytes and chromium-shadowed erythrocytic membranes were studied electron-microscopically. (auth)

58114 ELECTRON MICROSCOPIC STUDY ON ACUTE THYMIC INVOLUTION INDUCED BY POLYOMA VIRUS INFECTION. **Imamura, Masakatsu; Matsuyama, Tsutomu; Toh, Kentaro; Okuyama, Tomizo (Sapporo Medical Coll.). J. Nat. Cancer Inst.; 47: No. 2, 289-99(Aug 1971).**

Acute thymic involution induced by polyoma virus (PV) in AKR mice was studied ultrastructurally. The involuted thymuses were characterized by the presence of abundant nuclear debris derived from thymic lymphocytes (TL). Besides intercellular spaces, TL were included within the cytoplasm of epithelial reticular cells and macrophages. In epithelial cell cytoplasm, TL often contacted the nuclear membrane, and occasionally the limiting membrane, which surrounded these TL, was obscured. PV particles were often detected in epithelial cell nuclei and in phagosomes of macrophages. Their presence in epithelial cell nuclei and the consequent development of epithelial thymoma in adults strongly suggest that epithelial cells in the thymus are susceptible to PV and are transformed just after PV infection at the neonatal period. Their roles in lymphogenesis during early life and in regulation of peripheral lymphocytes suggest that TL destruction is caused by the functional alteration of the epithelial reticular cells. PV particles were not found in most of the destroyed TL, and direct viral participation in TL destruction was not evident. Peculiar osmiophilic dense structures occasionally observed near the altered TL nuclei were studied morphologically and compared with structures detected in thymuses involuted by cortisone or x irradiation. (auth)

58115 ROLE OF BONE MARROW OF X-IRRADIATED MICE IN THYMIC RECOVERY. **Blomgren, Henric (Karolinska Institutet, Stockholm). Cell Tissue Kinet.; 4: No. 5, 443-61(Sep 1971).**

The influence of the bone marrow on the repopulation of the thymus in x-irradiated mice has been investigated. It was observed that the thymus and a certain population of bone marrow lymphocytic cells were repopulated in parallel in a cyclic fashion. This occurred either after a single exposure of mice to 400 R or after serial weekly x-ray treatments with 170 R. Lethally irradiated recipients which were grafted with bone marrow cells obtained 12–24 days after four weekly irradiations of donor mice with 170 R also exhibited a cyclic repopulation of both the thymus and the bone marrow lymphocytic population. In contrast, mice which were transplanted with bone marrow cells from unirradiated donors, containing an equal number of stem cells (CFU), exhibited a continuous rather than a cyclic recovery of both cell populations. The bone marrow stem cells of mice recovering from x-irradiation were found to have a decreased proliferative activity, since they produced significantly smaller spleen colonies in lethally irradiated recipients than marrow cells from unirradiated mice. The results were interpreted as indicating that the bone marrow lymphocytic cells may act as thymic precursor cells and that thymic lymphopoiesis is dependent on the presence of such cells. Evidently, the production of lymphocytic cells will decrease when the stimulus for granulocyte production increases due to the limited proliferative activity of the surviving bone marrow stem cells after irradiation. This may result in a cyclic variation of the production of bone marrow lymphocytic cells and it follows that thymic lymphopoiesis will run parallel. (auth)

58116 EFFECT OF X-IRRADIATION ON MITOTIC ACTIVITY OF BONE MARROW CELLS OF LABORATORY AND WILD RATS. **Badr, F. M.; Badr, Ragaa S. (National Research Centre, Cairo). Folia Biol. (Prague); 17: No. 4, 258-63(1971).**

Changes in mitotic activity of bone marrow cells of wild (Rattus rattus) and laboratory (Rattus norvegicus) rats irradiated with x-ray doses of 400, 600, 800 and 1,000 R were followed 4 hours, 24 hours and then weekly till the fourth week after the treatment. Significant differences were found between the two strains of rats. Before irradiation, the mitotic index was higher in wild rats, but their lower radiation resistance resulted in a significantly greater depression of mitotic activity after 400 and 600 R. In accord with that, recovery from radiation-induced mitotic inhibition was evident earlier in laboratory rats, starting already in the third postirradiation week. (auth)

58117 MORPHOLOGICAL CHANGES IN THE SPLEEN OF IRRADIATED MICE NINE DAYS AFTER THE TRANSPLANTATION OF HOMOLOGOUS BONE MARROW. **Viktora, L. (Inst. of Haematology and Blood Transfusion, Prague). Folia Morphol.; 19: No. 2, 182-6(1971).**

The state of haematopoiesis in the spleen and the participation of the individual blood components was studied in lethally irradiated mice nine days after the transplantation of preserved fresh homologous bone marrow. It was found that erythropoiesis played the major part, and that granulocytopoiesis also participated significantly, in the regeneration of haematopoiesis in this phase. (auth)

58118 ELECTRON MICROSCOPIC OBSERVATIONS OF RAT MEDULLARY RETICULAR TISSUE AFTER SHORT-TERM, WHOLE BODY GAMMA IRRADIATION. **Dodson, Ronald F. (Baylor Coll., Houston, Tex.). Acta Neuropathol.; 17: 353-62 (1971).**

The ultrastructural observations recorded after shortterm, whole body gamma irradiation on medullary reticular tissue were evaluated. Twenty-five adult rats were divided into one control and four irradiated groups which received 1,000 rads, 2,000 rads, 5,000 rads, and 10,000 rads, respectively. Tissue preparations in each group consisted of immersion fixation in veronal acetate buffered OsO_4 and a perfusion technique utilizing s-collidine buffered glutaraldehyde. The micrographs from the control group revealed conformity to neurological ultrastructures as reported by other authors, with one exception. A structure termed "concentric membranous body" (CMB) was observed in the s-collidine buffered, perfused animals. This structure was noted to be associated with neuronal membranes and to contain laminated repeating intraperiodicity of 40 to 50 Å. In all irradiated groups (1,000, 2,000, 5,000, 10,000 rads) membranous swirls were observed. These structures appeared to be of CMB origin in the lower exposure groups and from both CMB and myelin sheath breakdown in the higher groups. Progressive cytoplasmic vacuolization, mitochondrial, and myelin sheath damage were noted as being related to dose level. Since no apparent capillary bed damage was observed in any irradiated animal, it was concluded that the cellular abnormalities recorded were the result of direct or localized irradiation damage of the brain. (auth)

58119 VARIATIONS IN THE RELATIONSHIPS BETWEEN TOTAL ^{59}Fe UPTAKE AND THE UPTAKES INTO HEME AND NONHEME FRACTIONS OF SPLEEN AND BONE MARROW IN IRRADIATED MICE AND MOUSE RADIATION CHIMERAS. **Gresham, P. A.; Barnett, M.; Goksoy, K.; Smith, S. Vaughan (Univ. of Birmingham, Eng.). Blood; 38: No. 3, 343-52(Sep 1971).**

A chemical method for the separation of heme and nonheme iron-containing fractions in mouse tissues has been used to study the uptake of ^{59}Fe into both the heme and nonheme iron fractions in spleen and femoral bone marrow, in order to investigate the possible relationships between the total uptake into spleen tissue and the rate of uptake into the heme fractions. In control mice, only about one third of the ^{59}Fe is directly associated with heme during the first day after administration, and this fraction decreases as radioactive red cells are released from the spleen into blood. Ten days after x-irradiation of mice, the proportion of ^{59}Fe in the spleen heme fraction 6 hr after intraperitoneal administration decreased about 30 to 10% of the total splenic activity as the radiation dose was increased from 500 to 750 rads. A similar alteration in the proportion of ^{59}Fe in the spleen haem fraction occurred in mouse radiation chimeras as the dose of injected syngeneic bone-marrow cells was reduced from 5×10^5 to zero. Similar results were found in femoral bone marrow. These results indicate that in this system the rate of uptake into whole tissue is not a measure of the uptake into heme; it is necessary, therefore, to use the method involving the measurement of iron uptake into heme, rather than the total tissue uptake, when estimating hemoglobin synthesis or erythropoiesis. (auth)

58120 CHARACTERIZATION OF SMALL SIZE LYMPHOID CELLS IN IRRADIATED AND NORMAL MOUSE BONE MARROW. **Haot, J.; Haughton, G.; Revesz, L. (Karolinska Institutet Medical School., Stockholm). Exp. Cell Research; 66: 171-6(May 1971).**

Suspensions of bone marrow cells from irradiated and unirradiated mice were labelled with ^{51}Cr-sodium chromate or ^{59}Fe-citrate. Due to a specific release of the incorporated isotopes by treatment of the cells with H-2 isoantisera, on the average 25% of ^{51}Cr and 8% ^{59}Fe was liberated. Cells which survived antiserum treatment were able to incorporate ^{59}Fe at a normal rate. The results were related to the effect of the antisera on the volume distribution of the bone marrow cell population. In conjunction with previous cytologic studies, it was concluded that the cell population destroyed by antiserum treatment belongs to the lymphoid series. Erythroid cells, if destroyed at all, constitute only a minor component of the killed population. Lymphoid cells in the regenerating bone marrow of irradiated animals appeared to be as sensitive to antisera as the lymphoid cells of normal bone marrow. (auth)

58121 OSTEOGENIC PRECURSOR CELLS OF BONE MARROW IN RADIATION CHIMERAS. **Friedenstein, Alexander; Kuralesova, Albina I. (Inst. for Epidemiology and Microbiology, Moscow). Transplantation; 12: No. 2, 99-108(Aug 1971).**

A study of the osteogenic and hematopoietic capacities of bone marrow precursor cells was made by transplanting allogeneic marrow and semisyngeneic parental marrow under the renal capsules of F_1 hybrid mice. The results indicate that the osteogenic precursor cells (OPC) of semisyngeneic marrow remain active for protracted periods without replenishment by hematopoietic cells. The independence of OPC from hematopoietic cells is confirmed by transplants to lethally irradiated hybrids, since the OPC are capable of self-maintenance in this situation without the possibility of stem cells being provided by the recipient. It is concluded that marrow contains independent lines of OPC and hematopoietic stem cells. Allogeneic marrow is subject to immunological rejection, as is syngeneic male marrow transplanted to presensitized females. (auth)

58122 CARDIOVASCULAR CHANGES IN EXPERIMENTAL RADIATION DISEASE. STUDY OF THE LITERATURE OF THE PERIOD 1965–1969. Kuna, P. Cas. Lek. Cesk.; 110: No. 21, 486-91(1971). (In Czech).

The whole-body irradiation of laboratory animals causes marked cardiovascular changes. Literature data from the last 5 years point out the prevailing hypotension with changes in vascular permeability and heart action. In the histologic preparations most frequently are encountered haemorrhages, degenerative changes of the myofibrils and subsequent fibrosis. There is a decrease in oxygen consumption, quantity of macroergic phosphates and in the nucleic acids. Furthermore potassium leakage, sodium accumulation and change in the activity of a number of enzymes take place. The results obtained by individual authors frequently are contradictory. Of interest is the favorable effect of radioprotective agents on some postirradiation changes in the myocardium. (auth)

58123 EFFECT OF BONE MARROW HOMOTRANSPLANTATION ON ^{32}P INCORPORATION INTO CELLULAR PROTEIN OF THE LIVER, SPLEEN, AND BONE MARROW IN ACUTE RADIATION SICKNESS. Shamrai, A. E. Vrach. Delo; No. 5, 127-9 (1971). (In Russian).

Rats were x-irradiated and bone marrow was transplanted intravenously 24 hr later. Thirty min later the animals were injected with ^{32}P. A marked increase in ^{32}P incorporation was observed on the fourth day followed by a decrease up to the thirteenth day. The decrease was prevented by homotransplantation. Animals not receiving transplants died by the thirteenth day. The temporary decrease in ^{32}P incorporation noted on the third day is apparently associated with suppression of protein synthesis by the presence of foreign proteins in the recipient. It is suggested that normalization of protein synthesis is one of the favorable influences of bone marrow transplantation in irradiated recipients. (H.L.W.)

58124 EFFECT OF PARTIAL MARROW SHIELDING ON HEMATOPOIETIC RECOVERY IN HEAVILY IRRADIATED MICE. Ito, Takaaki; Ito, Akihiro; Imamura, Nobutaka; Kawase, Akira; Yamasaki, Takao (Hiroshima Univ.). Hiroshima Daigaku Genbaku Hoshano Igaku Kenkyusho Nenpo; No. 10, 61-74(May 1969). (In Japanese).

The present experiments were undertaken to assess the effect of partial body shielding on the recovery of the hematopoiesis and lymphopoiesis in lethally irradiated animals. The hematopathological and autoradiographic assays for spleen colony formation were applied to heavily x-irradiated mice in which either the shielded limb was amputated at various intervals after x-irradiation or the various doses of sublethal x-irradiation were given to a shielded limb. The hematopoietic recovery was markedly promoted by the shielding of one hind limb. This effect seemed to be attributable to the repopulation of hematopoietic cells in irradiated sites, which is generated by the hematopoietic stem cells (HSC) from the shielded marrow. The number of HSC in the shielded marrow showed no significant decrease during the first 5 hours after x-irradiation though certain numbers of HSC appeared to migrate to the irradiated sites during this period. The migrating HSC appeared to possess affinity to certain specific sites according to their potential cell type: erythroid cells to the spleen and granuloid cells to the bone marrow. Megakaryocytes were distributed approximately equally in both spleen and marrow. The decrease of migrating ability or mitotic inhibition of HSC would be brought about by a relatively small dose (200 R), leading to the retardation of the hematopoietic recovery of the irradiated sites as compared to mice, a part of whose hematopoietic sites has been completely shielded during irradiation. The partial shielding of hematopoietic sites gave also a beneficial effect to the recovery of the lymphoid tissues. In this process, the regeneration of the peripheral lymphoid tissues such as white pulp of the spleen or lymph nodes was preceded by that of thymus. (auth)

58125 STUDIES ON LOCAL CIRCULATION IN X IRRADIATED SKIN BY USING ^{131}I. Kanasaki, Yoshiki (Osaka Medical Coll., Takatsuki, Japan). Osaka Ika Daigaku Zasshi; 28: No. 3-4, 256-71(Dec 1969). (In Japanese).

Patients undergoing x-ray treatment of the subcutaneous tissues were injected subcutaneously with ^{131}I for studies on dermal circulation. The disappearance rate of ^{131}I in the skin was obtained from the half time by measuring and recording changes in radioactivity. The disappearance rate in the femoral skin of x-irradiated rabbits was compared with that of human subjects. Disappearance rates increased in x-irradiated skin and the rate was higher in the dorsal than in the abdominal area. Effects of age on disappearance were also studied. (Japan)

58126 BIOCHEMICAL INDICATORS OF RADIATION INJURY: PRESENT STATUS AND PROSPECTS. Gerber, G. B. (EURATOM, Brussels. SCK/CEN, Mol, Belgium). pp 705-17 of Advances in Physical and Biological Radiation Detectors. Vienna; International Atomic Energy Agency (1971).

From Symposium on new developments in physical and biological radiation detectors; Vienna, Austria (23 Nov 1970). See STI/PUB-269; CONF-701112.

Use of biochemical indicators represents an attempt to assess radiation injury on the basis of metabolic changes in the irradiated organisms. Early effects of radiation may be classified as cellular effects (interphase death, delayed transit through the cell cycle, and reproductive failure) and systemic effects. Among these changes, interphase death and systemic effects are best accessible to biochemical tests, but are perhaps less important for the survival of the organism than is reproductive failure of cells. Nevertheless, biochemical indicators respond early and measurements are easy to execute; they may therefore be of value for an early assessment of the extent of radiation injury despite their low specificity. Examples of various types of biochemical indicators in the irradiated body are presented and the metabolic mechanisms involved in these changes are discussed. (auth)

58127 CLEFT PALATE AND/OR OLIGODACTYLIA IN THE MOUSE EMBRYO INDUCED ON DIFFERENT DAYS OF PREGNANCY BY VARIOUS DOSES OF X RAYS OR CYCLOPHOSPHAMIDE. Gebhardt, D. O. (National Inst. of Public Health, Utrecht). Acta Morphol. Neer.-Scand.; 8: 240-1(Feb 1971).

Pregnant mice were x-irradiated with different doses and treated with cyclophosphamide at various stages of development. The largest frequency of malformations was obtained when the mice were irradiated on the twelfth day. At term all fetuses had a reduced number of digits of the forelimbs and 96% had a cleft palate. It was concluded that: the optimal stage for the induction of a malformation depends on the nature of the teratogenic agent; the induction of cleft palate by x rays is a process which is independent of the induction of oligodactylia; and the changes in development caused by administering a teratogenic agent on various dose levels can best be studied using a three dimensional model with a time, dose, and effect axis. (H.L.W.)

58128 MORPHOLOGICAL STUDY OF ORGANS, BLOOD CELLS, AND BONE MARROW OF WHITE RATS AND MICE WITH VACCINAL DISEASE. Svet-Moldavskaya, I. A.; Yumasheva, M. A.; Shershukova, E. M.; Ravkina, L. I.; Osipova, T. V. (Research Inst. of Viral Preparations, Moscow). Acta Virol. (Prague) Engl. Ed.; 14: No. 3, 257-60(1970).

Histological examination revealed inflammation foci, mainly in the lungs, in animals in which the terminal stage of vaccinal disease developed. Similar lesions were observed in the lungs of irradiated but uninfected animals and in non-irradiated animals inoculated with the same dose of virus. The changes in the bone marrow and blood cells were similar to those observed in animals after irradiation, regardless of virus administration. A possible mechanism of the development of vaccinal disease is discussed. (NSA of Czech)

58129 NEUROSECRETION CELLS OF THE DOG HYPOTHALAMUS DURING ACUTE RADIATION SICKNESS. Pishchinskii, A. V.; Chevlytko, A. A. (Minsk Medical Inst.). Dokl. Akad. Nauk BSSR; 15: No. 3, 277-9(Mar 1971). (In Russian).

A study was made of the neurosecretory cells of the hypothalamus of 13 dogs in the terminal stages of radiation sickness. The latter was caused by whole-body irradiation of 600 R. It was observed that whole-body irradiation brings about not only a disturbance in the neurosecretory process (cell destruction, a setback in cell secretion), but also significant destructive changes in the secreting cells (shrivelling, vacuolization of the cytoplasm). (tr-auth)

58130 REPAIR OF RADIOLESIONS RESPONSIBLE FOR THE FORMATION OF MICRONUCLEI AND ANA-TELOPHASE BRIDGES IN THE RAT LIVER. Barbason, H. (Univ., Liege). Arch. Biol. (Liege); 81: 51-60(1970). (In French).

Whole-body irradiation of rats with 450 R x radiation produced nuclear lesions in liver cells. These lesions manifest themselves histologically during regeneration following partial liver resection. When the resection was performed immediately after radiation, the mitotic index was partially inhibited and the mitoses were associated with the important production of micronuclei and anatelophase bridges. Evolution of these mitotic anomalies was studied by separating liver resection and irradiation through different time spans. During the first six weeks of such delay, restoration of mitotic activity coincided with diminution of micronuclei and augmentation of bridges. When the delay reached up to 15 weeks, the number of micronuclei remained practically stable, whereas bridges diminished significantly. The differences between origin of micronuclei and origin of the bridges were analyzed and a hypothesis proposed. (H.B.G.)

58131 (CEA-CONF-1768) STUDY OF CELLULAR ULTRASTRUCTURE AND MITOTIC INDEX IN VITRO OF LYMPHOCYTES OF CHRONIC LYMPHOID LEUKEMIA DURING TREATMENT OF THE BLOOD BY EXTRACORPOREAL IRRADIATION. Marcille, Melle G.; Sotto, M. F.; Schaerer, R.; Suscillon, M.; Patet, J.; Hollard, D. [nd]. 16p. (In French). (CONF-700820-2). Dep. NTIS (U. S. Sales Only).

From thirteenth international congress of hematology; Munich, Germany (24 Aug 1970).

Two techniques were used to discover whether the extracorporeal irradiation of the blood of chronic lymphocytic leukemia either reduced the number of lymphocytes, or contributed to the disappearance of these cells and their replacement by normal lymphocytes: the circulating lymphocytes were observed with an electron microscope; the mitotic index was measured in a lymphocytic culture in the presence of phytohemagglutinin. Morphological details observed by means of electron microscopy of the lymphocytes are described and illustrated. (France)

58132 STUDY OF IMMEDIATE RETRANSPLANTATION OF X-IRRADIATED MANDIBLE AFTER MANDIBULAR RESECTION. I. CLINICAL RESEARCH. Sato, Kimihiko (Kyushu Dental Coll., Kitakyushu, Japan). Kyushu Shika Gakkai Zasshi; 24: No. 2, 141-59(Jul 1970). (In Japanese).

The immediate retransplantation of mandibular pieces, from which visible lesions were removed, was performed following a single 5000 R x-ray exposure. The cases consisted of a cancer group (4 cancers) and a non-cancer group (a mixed epidermoid and follicular cyst, mycosis, osteoma, and ameloblastoma). Particular differences between the cancer group and the non-cancer group were revealed by clinical and roentgenological studies from 6 months to 34 months after the operation. In the cancer group, 5 months postoperative x-ray films showed that pseudoarticulation formed at the conjunctive portions of the retransplanted mandible and the host. However, the retransplanted ascending ramus functioned well in its role. New bone formation surrounding the grafts or enlargement of the transplanted bone itself, which was observed in cases of fresh autogenous graft, could not be seen. The effects of pre- and postoperative x irradiation on the surrounding soft tissues were greater than that of the 5000 R single irradiation on the retransplanted mandibular pieces. In the non-cancer group, callous production began at the contact portion of the remaining mandible and the retransplanted mandibular pieces by 2 or 3 weeks after the operation. Further, resorption and smoothing of sharp edges of the transplanted mandible were observed. The functional reconstruction of the transplanted mandible continued day after day resulting in mandibular arch recovery. Moreover, new bone formation was observed at the alveolar edges or the portion of the process coronoideus and it connected partly to the retransplanted mandible. However, the enlargement of transplanted bone observed in fresh autogenous bone grafts could not be seen in the present grafts and the speed of functional reconstruction was slower in comparison with fresh autogenous bone graft. No recurrent tumor from retransplanted mandibular pieces was observed during this period. (auth)

58133 HETEROTOPIC BONE FORMATION IN THE LUNG. Kamada, Toru; Hara, Hiroshi (Hiroshima Univ.). Hiroshima J. Med. Sci.; 19: No. 1, 11-21(Mar 1970).

Three cases of heterotopic bone formation of the lung unassociated with tuberculous scars have been reported. Two of them are cases of multiple myeloma. The lung is characterized by formation of discrete small nodules of bone sparsely distributed in the alveolar spaces throughout the organ. Bone formation in the lungs of rabbits caused by repeated x-ray irradiation and administration of adrenocortical hormones was described. The picture of bone formation in rabbits was remarkably similar to that seen in the autopsy cases. The pathogenesis of heterotopic bone formation in the lungs was discussed. (auth)

58134 EXAMINATION OF BLOOD COUNTS ON THE RADIOLOGICAL TECHNICIANS IN JAPAN. Endo, Kouichi; Ishizaka, Masatsuna (Inst. of Public Health, Tokyo). Nippon Hoshasen Gijutsu Gakkai Zasshi; 26: No. 5, 1-8(Mar 1971). (In Japanese).

A survey was conducted of radiation hazards to clinical radiation technicians working in health centers, national hospitals, national sanitoriums and some general hospitals during 1969. Based on the observation that disturbances in the hemopoietic system are the most pronounced symptoms of radiation hazard, data on blood counts in these workers was statistically evaluated as follows. The average blood count and standard deviation of these blood counts in all radiation technologists in the institutions mentioned above were as follows: WBC 6,298 ± 1,359/mm^3 (1,428 persons), RBC 468 ± 48 × 10^4/mm^3 (1,413 persons), and Hb 93.7 ± 9.1% (1,326 persons). Several blood tests are conducted every year on radiological technicians. The yearly fluctuation of cell counts for WBC was less than 5,000/mm^3 in 36.3% and for RBC less than 450 × 10^4/mm^3 in 66.9%. Classification of blood cell counts into normal and abnormal values revealed abnormal values for either RBC or WBC in about one-half of the cases. In 131 persons, abnormal values for both were noted. In persons with a history of radiation hazard in the past, the WBC was significantly lower than in those technicians without radiation hazard. (auth)

58135 VESICOVAGINAL FISTULA, RADIATION, AND GYNECOLOGIC CANCER. Boronow, Richard C.; Rutledge, Felix (Anderson Hospital and Tumor Inst., Houston, Tex.). Amer. J. Obstet. Gynecol.; 111: No. 1, 85-90(1 Sep 1971).

Radiation and combined radiation and surgical procedures were common denominators in 73 vesicovaginal fistulas reviewed. Only 1.2% of 2,729 patients with cervical cancer treated by radiation therapy developed vesicovaginal fistula. The rate was definitely higher in the small number of cases that had combined radiation and hysterectomy. These data show little difference in the rate of fistula formation when correlated with clinical stage of a cervical cancer. The major management experience involved colpocleisis (either complete or partial) and urinary diversion (primarily by ileal conduit but also by sigmoid conduit). Colpocleisis seems most suitable for patients with normal intravenous pyelograms, size and location of fistula permitting partial rather than complete colpocleisis, and a patient who will accept compromise of vaginal depth. Conduit urinary diversion is excellent for the fistula that cannot be closed vaginally. Other techniques, however, for vaginal fistula closure should be explored prior to selecting urinary diversion as the definitive method of management. (auth)

58136 EFFECTS OF IN VITRO ^{60}Co γ IRRADIATION ON ^{51}Cr-LABELED RED BLOOD CELLS. Ishikawa, Daizi; Yasukochi, Hiroshi (Tokyo Univ.). Nippon Igaku Hoshasen Gakkai Zasshi; 29: No. 12, 1501-6(Mar 1970). (In Japanese).

Gamma-irradiated ^{51}Cr-labeled red blood cells were administered to the patient for scanning of the spleen. By this method, the reproducibility of the degree of destruction of red blood cells was superior than that of the heat treating method and better scintigrams are obtained. An investigation was performed on the degree of destruction of the red blood cells by γ irradiation. Extensive destruction of the red blood cells started at doses of about 300,000 R and 25% of the red blood cells were destroyed at 400,000 R. The best scintigrams were obtained using the red blood cells irradiated at doses between 300,000 and 340,000 R. Several comparisons were made between γ-treated and heat-treated red blood cells. Red blood cell aging induced by γ irradiation was suggested by the daily destruction of cells stored in a freezer after 350,000 R irradiation. The degree of destruction of red blood cells was 50% at one day after irradiation and 90% after two days. The determination of the cell aging must be made by cell survival determinations in the patient (in vivo), but this in vivo decay suggests the shortening of the cell survival determination method if a correlation between the irradiation dose in vitro and cell survival in vivo is obtained. The aging of red blood cells by ^{60}Co γ irradiation is discussed in comparison with that of the heat treating method and some clinical applications are suggested for spleen scintigram procedures and red cell survival determinations. (auth)

58137 RADIOTHERAPY OF LUNG CANCER. Yamada, Masahiro; Nagase, Tetsuya (Keio Univ., Tokyo). Rinsho Kagaku; 6: No. 4, 475-80(Apr 1970). (In Japanese).

A broad review of radiotherapy of lung cancer, mainly from published literature, is presented. In principle, irradiation is made by a two-field method, the standard dose being 5000 to 6000 rads for undifferentiated carcinomas, 6000 to 7000 rads for squamous cell carcinomas, and above 7000 rads for adenocarcinomas. Diminution by irradiation, as judged from tumor shadow, is 17% for sieve x radiation, 23% for high-dose ^{60}Co irradiation, and 28% for super-high voltage x irradiation. The unchanged rates are 45%, 25%, and 10%, respectively, showing the effectiveness of super-high voltage x irradiation. The tumors liable to undergo diminution are undifferentiated carcinomas with strong sensitivity followed by squamous cell carcinomas and adenocarcinomas. However, the therapeutic rate is poor in undifferentiated carcinomas and good in squamous cell carcinomas. One-yr survival rates are 20% for sieve x irradiation, 30% for large-dose ^{60}Co, and 40% for super-high voltage x-ray therapy, still showing the good effect of the last therapy. The difference between these decreased to 11, 15, and 20% for 2-yr survival and no great difference was seen for 3-yr survivals due largely to the frequency of deaths due to metastasis 2 to 3 yrs after radiotherapy. Surgery and chemotherapy are being used to raise this survival rate but current results are not good. Radiotherapy often results in radiation pneumonia corresponding to the site of irradiation, often progressing to fibrosis of the lung or resulting in myocardial damage when irradiation is over a wide field. Radiation myelitis is often seen in aged patients. (Japan)

58138 RADIATION EXPOSURE IN AIR TRAVEL. Schaefer, Hermann J. (Naval Aerospace Medical Research Lab., Pensacola, Fla.). Science;/173: No. 3999, 780-3(27 Aug 1971).

The prospect of present-day, large-scale passenger operations shifting from jet aircraft to supersonic transports (SST), flying at two to three times the speed of sound and at altitudes of 60,000 to 65,000 feet, has raised the question of what harmful effects the substantially higher levels of environmental radiation could have on crew members and passengers. An evaluation and comparison of the environmental radiation levels at conventional jet and at SST altitudes is presented. It is concluded that levels of ionizing radiation at the high altitudes encountered during supersonic transport will not significantly increase the population dose. (C.H.)

58139 IRRADIATION HAZARD IN MEDICINE. A PRESSING PROBLEM. Fridrich, R. (Univ., Basel). Praxis (Bern); 60: 5-12(5 Jan 1971). (In German).

Somatic and genetic radiation effects on man are reviewed. In highly industrialized countries, natural background radiation amounts to about 120 mrad/year, whereas exposure through industry and medicine contributes 30 to 40 mrad/year/person. A comparison was made of the radiation burden between x radiation and radioisotope diagnostic procedures. It was concluded that neither industrial nor medical application of radiation represents a noticeable risk to mankind. Nonetheless, only those physicians with special training should use radiation equipment. (H.B.G.)

58140 IRRADIATION CHANGES IN NORMAL AND ATYPICAL SQUAMOUS EPITHELIUM OF THE CERVIX UTERI. Hilgarth, M. Med. Lab.; 23: 185-8(Aug 1970). (In German).

With respect to local recurrence of cervical tumors, the cervix epithelium in 40 patients was studied cytologically and histologically following radium, roentgen, and telecobalt therapy. In 29 patients, agreement existed between cytological and histological findings. Eleven patients showed disagreement, whereby the cytological results proved falsely negative in 10 and falsely positive in one. It was concluded that cytological tests were valuable for detecting local recurrence of tumors; however, because of their technical and morphological difficulty, they should only be performed with the necessary reservation by experienced investigators. (H.B.G.)

58141 INFLUENCE OF BODY INHOMOGENEITIES ON DOSE DISTRIBUTION DURING ELECTRON AND ROENTGEN IRRADIATION WITH A 42 MeV BETATRON. Fehrentz, D.; Franz, K.-D. (Univ., Heidelberg). Therapiewoche; 21: No. 19, 1551-2; 1554; 1557-9(12 May 1971). (In German).

The fact that electron therapy only slightly damages tissue behind the target area can be utilized for deep therapy with electrons in excess of 20 MeV. Recommended is application of moving beam radiation to compensate the effects of inhomogeneities on dose distribution, especially dose peaks caused by electron scattering. Under this condition, sufficient protection can be obtained for skin and healthy tissue surrounding the tumor. With ultrahard roentgen rays, up to 45 MeV, bone dose is only insignificantly higher than that to the muscle. X radiation of such high energy proved advantageous in obese patients where target areas must be irradiated at a depth of more than 8 cm. (tr-auth)

58142 MECHANISMS INVOLVED IN THE PHARMACODYNAMIC SENSITIVITY CHANGES IN IRRADIATED ORGANISMS. Voicu, V. Rev. Sanit. Mil.; No. 1, 21-5(Jan-Feb 1970). (In Rumanian).

Ionizing radiations affect the permeability of membranes, enzyme systems, cell morphology, and excretion processes. The central nervous system is considered radiation resistant, up to about 2000 R. Radiation sensitizes the brain, lowers the threshold for the activity of drugs, and inhibits their metabolism by hepatic enzymes. Sensitivity of the organism toward cholinergic substances is affected by changes of cholinesterase after irradiation. The great variety of experimental conditions and doses used for radiation experiments make it difficult to interpret morphofunctional behavior of the heart after exposure. The effect of radiation is revealed by changes in the ECG and by heart rhythm disturbances. The catecholamine concentration in the blood and myocardium is increased both immediately after irradiation and during the peak period of radiation sickness. Radiation reduces the active bound calcium capacity by weakening the bonds, thereby reducing the concentration of cardiotonic agents needed to trigger specific phenomena in the myocardium. These effects must be taken into consideration when developing a therapy for people affected by radiation sickness. (TTT)

58143 EFFECTS OF IRRADIATION ON THE CENTRAL NERVOUS SYSTEM. Tsuya, Asahi (Japanese Foundation for Cancer Research, Tokyo). Gan No Rinsho; 16: No. 6, 658-63 (Jun 1970). (In Japanese).

Fundamental research on the effects of radiation on the central nervous system was carried out over a period of six years by the Ministry of Education. A review of results is presented concerning radiosensitivity, permissible doses, physiological changes, histological changes, clinical findings, and radiation dose necessary to produce cerebral death. Radiation damage to nerve tissue was estimated by direct and indirect methods. Time factors were also examined and results are tabulated. A brief summary of the report of the UNESCO committee on radiation risk is given and plans for future studies are listed. (Japan)

58144 EFFECT OF CHRONIC RADIATION ON THE RESULTS OF THROMBOELASTOGRAPHIC EXAMINATIONS (TEG). Kriklava, J.; Koskova, D. Cas. Lek. Cesk.; 109: No. 33, 761-3(31 Jun 1970). (In Czech).

Thromboelastographic examinations were made in miners of uranium mines exposed to small doses of chronic radiation. Thromboelastographic records were compared with a control group that did not have any contact with ionizing radiation and the results were computed statistically. As to basic TEG values (r, k, ma, mE, and t-ma), there were no significant differences between exposed subjects and controls. There was a significant difference in the firmness of the thrombus but only 90, 120, and 150 min after the onset of coagulation, in the subjects exposed for a prolonged period. There, however, the greater fibrinolytic serum activity is more manifest and is more potentiated. (auth)

58145 DEOXYCYTIDINURIA IN PERSONS OCCUPATIONALLY EXPOSED TO CHRONIC IRRADIATION. Grozdanovic, J.; Vich, Z.; Kratochvil, J.; Truxova, G. Cas. Lek. Cesk.; 109: No. 33, 759-60(31 Jun 1970). (In Czech).

It was revealed that in subjects working in uranium mines, CdR-uria is slightly raised; as compared with a group of workers working on the surface, the difference was, however, not statistically significant. The raised levels of CdR-uria are apparently still within the physiological range. Attention is drawn to the possible effect of the age factor on the level of CdR-uria. (auth)

58146 STUDY OF CELLULAR DIVISIONS IN NORMAL HUMAN EPIDERMIS AND UNDER THE INFLUENCE OF X RAYS. Bogdan, F. Stud. Cercet. Embriol. Citol., Ser. Embriol.; 7: No. 2, 169-74(1970).

The results of an investigation undertaken on normal human tegument from 20 operatory slides for irradiated and non-irradiated mammary neoplasms, histologically processed, stained, and quantitatively microscopically examined are reported. Cellular divisions occur in the local basal stratum (excluding mitoses), and the epidermal spinous stratum (predominantly amitoses and endomitoses in its medium and upper thirds); the irradiating factor induces a lowering of the number of epidermal cellular divisions: 25 days after the last irradiation they are only 50% of the divisions reported in the nonirradiated epidermis. (Rom. Sci. Abstr.)

58147 IRRADIATION SEQUELAE IN THE HEART AND MAJOR VESSELS. Kolar, J. (Karls Univ., Prague). Med. Klin. (Munich); 66: No. 18, 661-8(30 Apr 1971). (In German).

The effects of radiotherapy of thoracic diseases on heart and blood vessels are discussed. Radioinduced pericarditis occurs in some patients. Heart infarcts, however, virtually never occur as a sequela of radiation treatment. Various types of functional disturbances of heart rhythm are observable; they usually are transient and harmless. Radiation can act as a contributing factor in the rupture of heart and vessels during myocardial necrosis. Obliteration of arteries should be considered more seriously as a possible radiation effect. Radioinduced arteriosclerosis remains problematic. Frequency of heart and vessel complications following radiotherapy is so small as to require no change in the normal techniques of radiotherapy. 121 references are given. (H.B.G.)

58148 RADIOSENSITIVITY STUDIES IN SUNFLOWER (HELIANTHUS ANNUS). Rajput, M. A.; Khan, A. H. (Radiation Genetics Inst., Lyallpur, India). Nucleus (Karachi); 8: No. 1-2, 84-7(Jan-Jun 1971).

Air-dried seeds of three varieties, namely, Thatta, Peredovic and HO-1 having 7% moisture content were subjected to 1, 2.5, 5, 7.5 and 10 kR doses of gamma-rays from a 250-curie ^{60}Co source. It has been concluded from these experiments that the variety Peredovic is more susceptible to gamma-rays than the others, and the order of radiosensitivity is Peredovic, Thatta, and HO-1. (auth)

58149 RESISTANCE OF SEEDS OF LUPINE VARIETIES TO X RADIATION. Anokhin, A. S.; Anokhina, V. S. (Minsk Pedagogical Inst.). Vestsi Akad. Navuk BSSR, Ser. Biyal. Navuk; No. 3, 56-9(1971). (In Belrussian).

A study of the resistance to 12 kR doses of x-radiation was conducted on narrow-leaf lupine hybrids and original parental forms. Resistance was judged from germination and survival rates. Intervarietal lupine hybrids differed in their degree of resistance to x-radiation within broad limits, from a high degree to total absence of resistance. Those varieties with marked heterosis exhibited a significant degree of radiation resistance, as compared to those lacking heterosis. (tr-auth)

58150 SOME EFFECTS OF IONIZING IRRADIATION ON THE MICROFUNGAL POPULATIONS OF QUERCUS RUBRUM LITTER. Martin, James Weldon. Columbia, S. C.; Univ. of South Carolina (1971). 85p. University Microfilms Order No. 71-21,847.

Thesis.

Microfungal populations inhabiting the litter in a Savannah River Plant forest dominated by Quercus rubrum were studied for 2 months before and 9 months after irradiation by a 9200 curie 137-cesium source. Six experimental sites received from approximately 2500 K R to 4 K R while two control sites received only background radiation. Pre-irradiation studies showed a high degree of similarity between populations in all sites. Immediately after irradiation the three most heavily irradiated sites displayed much lower populations and vastly different species composition than lightly irradiated and control populations. Darkly pigmented fungi withstood irradiation up to 2500 K R and became the dominant species of the immediate post-irradiation populations. However, some lightly pigmented forms were re-established by one month after irradiation and populations of darkly pigmented forms were reduced to near normal. It is suggested that apparent high populations of certain species resulted in the elimination of competition rather than stimulation by ionizing irradiation. Return to normal populations is slow, since abnormalities were still in evidence 9 months after termination of irradiation. The use of irradiation to study functions of certain litter inhabiting species and groups of species by progressive elimination of them is proposed. (Diss. Abstr. Int., B)

58151 SENSITIVITY OF FRUIT AND BERRY PLANTS TO GAMMA RADIATION. Ravkin, A. S. Vestn. Sel'skokhoz. Nauki (Moscow); No. 12, 37-40(Dec 1970). (In Russian).

Critical and sublethal doses of gamma radiation were separately established for seeds, cuttings, rosettes, and entire plants of cultivated berries. Significant differences were indicated in radiation-resistant cultures, and varieties in connection with ploidy, natural variety, and the physiological state at the time of irradiation. Vegetative plants of some cultures are capable of undergoing somewhat higher doses than their seeds and cuttings. (tr-INIS)

58152 RADIOSENSITIVITY OF WHEAT GERM. Chekurov, V. M.; Enken, V. B. (Inst. of Cytology and Genetics, Novosibirsk, USSR). Izv. Sib. Otd. Akad. Nauk SSSR, Ser. Biol. Nauk; 3: No. 15, 74-8(Dec 1970). (In Russian).

Four types of wheat were selected for this study of the effect of x-radiation on the gynoecium and determination of the critical dose. With the onset of heading of the wheat the flowers of the maternal plants were castrated, irradiated with 1.5 to 7 kR of x-radiation, then pollinated with freshly gathered pollen of the same variety. Thirty days later the spikelets were cut and examined. Immediate destruction of the female gametes had apparently not resulted from this treatment. Increased dosage of x-radiation to 7 kR lowered caryopsis relative to the control samples by $2^1/_2$ times in soft wheat, and by 4 times in einkorn (Triticum monococcum). Survival rate was inversely proportional to the dose of radiation; the critical dose for the varieties studied was 5 to 7 kR. (K.S.W.)

58153 EFFECTS OF IRRADIATION (HIGH ENERGY β RAYS) ON CLADOPHORALES. I. CHAETOMORPHA MELAGONIUM. Patel, R. J. (Sardar Patel Univ., Vallabh Vidyanagar, India). Nucleus (Calcutta); 13: No. 2, 111-17(Dec 1970).

Five different doses up to 100,000 R of high energy β rays were given to Chaetomorpha melagonium at Hammersmith Hospital, London. Normal quadriflagellate swarmers at lower doses up to 5000 R and masses of non-separated, multiflagellate swarmers at higher doses were studied for the first time in algae. At highest dose, there was a small percentage of surviving swarmers although the plants receiving it died. The effects of irradiation on the chromosomes have been studied in detail. The chromosome aberrations were more frequent as the doses were increased. Effects on meiotic divisions were studied for the first time where 13 bivalents were counted, the normal being 12. Recovery was found up to 53,000 R after two weeks. Only 1 or 2 plants were found from the swarmers at 100,000 R. Cytological picture was normal in these filaments. It may be said that 100,000 R is the lethal dose for Chaetomorpha melagonium Kutz. (auth)

58154 EFFECT OF FERTILIZERS AND SEED IRRADIATION WITH GAMMA RAYS ON THE UPTAKE OF NUTRIENTS IN CORN PLANTS. Mar'ina, V. V. Visn. Sil'skogospodar. Nauki; No. 12, 50-3(Dec 1970). (In Ukrainian).

Experimental investigation showed that the uptake of nitrogen and phosphorus by corn plants in the tasseled stage was increased by irradiation with 1,000 rads of γ radiation. In Kiev-8 hybrid plants, which are more responsive to radiation, essential differences in the uptake of nutritive substances by the irradiated and control plants were noted in the absence of pre-sowing fertilization. In comparison with the controls, the irradiated plants utilized the nutritive substances of the soil and basic fertilizers better; uptake of nitrogen was increased by 9.5 to 32.9%, and phosphorus by 9.4 to 27.7%. The more active uptake in the Kiev-8 hybrid under these conditions was conducive to an increase in grain yield over a three-year average. (tr-INIS)

Radiation Effects on Microorganisms

58155 INFLUENCE OF SELENOUREA AND OF COLLOIDAL SELENIUM ON THE SURVIVAL OF E. COLI B/r AFTER X IRRADIATION. Badiello, R. (CNR, Bologna); di Maggio, Diassina; Quintiliani, M.; Sapora, O. Int. J. Radiat. Biol.; 20: No. 1, 61-8 (1971).

E. coli B/r irradiated in the presence of 5×10^{-2} M selenourea showed an increased survival when irradiated in air and the opposite effect in nitrogen. The anoxic sensitization appeared to be due to colloidal selenium formed by radiation from selenourea, whereas the latter seemed to be a protector most active in the presence of oxygen. This conclusion was based on the following experimental results: 5×10^{-2} M selenourea solutions showed the same effect when pre-irradiated with 150 krads before mixing with bacterial suspensions; colloidal selenium separated from a repeatedly-irradiated selenourea solution and resuspended in buffer was more active than the original selenourea solution in sensitizing anoxic bacteria and completely ineffective on bacteria irradiated in air; the sensitization of anoxic bacteria was decreased by resuspending colloidal selenium in fresh selenourea solution. (UK)

58156 SURVIVAL TIME OF AZOTOBACTER CHROOCOCCUM FOLLOWING γ IRRADIATION AND IBENZMETHYZINE TREATMENT. Boige, F.; Abbatucci, J. S.; Kauffmann, J.; Goussard, J. (Univ., Caen, France). Compt. Rend. Soc. Biol.; 164: No. 11, 2229-34(1970). (In French).

Cell concentration plays an important role in determining the resistance of Azotobacter chroococcum to radiation and ibenzmethyzine. The physiological state of the cells also has an effect on their survival: cells from relatively old populations are more resistant to cytotoxic action and eventual crossing, the extra cellular medium becoming relatively toxic and intervening in selecting the more resistant cells. As a result of the intercellular recovery facilities established for Azotobacter chroococcum, the cells at the end of the culture may be assumed to arise from a particularly rich enzyme system endowing them with a greater resistance to the medium. (France)

58157 RADIOPROTECTIVE EFFECT OF ETHYLENE GLYCOL ON BACTERIA. Pleceas, M.; Romanescu, Gh.; Arizan, D.; Hlevca, B. (Inst. of Hygiene, Bucharest). Arch. Roum. Pathol. Exp. Microbiol.; 29: No. 4, 623-7(1970). (In French).

Ethylene glycol was an effective radioprotective agent against gamma irradiation of Escherichia coli. Formaldehyde and sodium merthiolate enhanced the action of gamma rays on the bacteria. (H.L.W.)

Radiosterilization and Radiopreservation

58158 STERILIZING DOSES OF ULTRAVIOLET RADIATION AND ULTRASONIC WAVES IN TREATING WINE MICROFLORA. Avakyan, B. P. (Inst. of Viticulture and Fruitgrowing, Erevan). Biol. Zh. Arm.; 24: No. 1, 90-4(Jan 1971). (In Russian).

Various yeasts were subjected to ultraviolet light (dose was either 40,000 or 90,000 ergs/mm^2) and 20 kHz ultrasonic waves (5 to 9 sec) in an effort to develop a process of cold sterilization of the wine-making materials. Sterilizing doses of uv and ultrasound were established for their joint use in combating detrimental microflora. The irradiated microflora were quite sensitive to changes in dose of uv and ultrasound. An improvement in the wine quality was detected as a result of the use of cold sterilization. (K.S.W.)

58159 PRESENT STATUS OF NATIONAL RESEARCH PROJECT ON FOOD IRRADIATION. SPROUT INHIBITION OF POTATOES. Sato, Tomotaro (Japan Atomic Energy Research Inst., Takasaki). Nippon Genshiryoku Gakkaishi; 13: No. 3, 135-8(Mar 1971). (In Japanese).

The national research project on food irradiation was started in 1967, and is now making good progress in accordance with the program laid out for its activities. Sprout inhibition of potatoes and onions was the subject first selected for execution, and considerable study has been undertaken on the effects of irradiation and health hazards. A description is presented of the results obtained with investigations on potato, which is considered to be the most promising subject of such treatment. Large scale irradiation tests on three different varieties of potato indicated that potato sprout could be inhibited for 8 months when irradiated within 3 months of harvest to doses of 7 to 15 krad. Extensive investigations were conducted to determine the health hazards that would be occasioned by the irradiated potatoes. While the final conclusion is not yet to be reached, the results obtained so far do not indicate the existence of any problems related to health hazards associated with the irradiated potatoes. (auth)

58160 CHEMICAL AND PHYSICAL CHANGES OF DEXTRAN 40000 IRRADIATED WITH VARIOUS DOSES OF γ RADIATION. Derlikowski, Jerzy; Szyszko, Edmund; Zagorski, Zbigniew P. (Inst. for Drug Research and Control, Warsaw). Diss. Pharm. Pharmacol.; 23: No. 3, 253-7(1971).

The ^{60}Co γ radiation at doses 1.0 to 5.0 Mrad produces dose-dependent chemical and physical changes of the dry powder of dextran 40000. The doses below 1.0 Mrad do not produce such changes. As the radiodegradation of dextran 40000 is too rapid the dry powder of the preparation cannot be sterilized by ionizing radiation. (auth)

58161 MINIMUM STERILIZING DOSES OF X-RAY IRRADIATION FOR THE FIRST AND SECOND GENERATIONS OF THE RICE AND GRANARY WEEVIL. Reda Abdu; Sumarukov, G. V.; (Moscow Univ.). Vestn. Mosk. Univ., Ser. VI, Biol., Pochvoved.; 25: No. 5, 8-10(1970). (In Russian).

The effect of x-irradiation on adult rice and granary weevils was investigated with a view to ascertaining the critical dose of radiation, the sterilizing dose, and the survival rate. Doses of 8 kRad and over resulted in 100% mortality of rice weevils in 20 days, or granary weevils in 25 days. The $LD_{50/25}$ for granary weevils was 4.6 kRad; and for rice weevils 3.9 Krad. The sterilization dose for both species was 7 Krad. (KSW)

58162 EFFECT OF γ-IRRADIATED FRESH FISH ON WHITE RATS. Shillinger, Yu. I.; Osipova, I. N. Vop. Pitan.; 29: No. 5, 45-50(Sep-Oct 1970). (In Russian).

Freshly frozen fish subjected to γ irradiation in a dose of 600 krad was fed to three generations of albino rats. Any possible toxic properties of the irradiated fish and its influence on the reproductive function and progeny were studied. The irradiated fresh fish diet did not exert any marked toxic action on growth and development during three generations. There could be seen, however, a reduced activity of the blood butylcholinesterase in males of the primary generation, changes in the activity of the blood and liver aminotransferase in rats of the first generation, and depressed activity of succinate dehydrogenase and alanine aminotransferase in the liver of animals in the second generation. The irradiated fish diet had unfavorable effect on the gonads, reproductive function, and progeny, along with a certain rise in the number of intercurrent diseases in the laboratory animals. (auth)

58169 (ORNL-TM-3488) MASS TRANSFER BETWEEN HASTELLOY N AND HAYNES ALLOY NO. 25 IN A MOLTEN SODIUM FLUOROBORATE MIXTURE. Koger, J. W.; Litman, A. P. (Oak Ridge National Lab., Tenn.). Oct 1971. Contract W-7405-eng-26. 28p. Dep. NTIS.

The compatibility of Haynes alloy No. 25 and Hastelloy N with fused $NaBF_4$–8 mole % NaF was determined in the range 605 to 460°C. The cobalt-base alloy was inadvertently incorporated in the Hastelloy N thermal convection loop and was exposed to the fluoroborate salt mixture for 3660 hr. The Haynes alloy No. 25 suffered damage by selective leaching of cobalt and chromium, which migrated to the Hastelloy N. The mechanism of corrosive attack was activity-gradient and temperature-gradient mass transfer. Haynes alloy No. 25 is more susceptible to attack by the fluoroborate mixture than Hastelloy N. The presence of the small amount of Haynes alloy No. 25 in the system did not compromise later experiments on the monometallic Hastelloy N system. Penetration of deposited cobalt corresponded to a diffusivity of 5.6×10^{-15} cm^2/sec in Hastelloy N at 465°C. (auth)

58170 (RD/B/N-1998) OBSERVATIONS ON PARTICULATES IN A SODIUM LOOP. Hayes, D. J.; Pownall, D. R.; Smith, R. J. (Central Electricity Generating Board, Berkeley (England). Berkeley Nuclear Labs.). Jun 1971. 17p. Dep. NTIS (U. S. Sales Only).

A simple sodium loop which had completed 4000 hours operation at temperatures up to 500°C was examined for particulate matter. Six types of particles were found, ranging from micron-size α-iron particles and whiskers to millimeter-size metallic foil and particles, and two types of non-metallic crystals. All were found in regions consistent with the view that their distribution is governed by fluid flow and gravitational forces. More α-iron was found than would be expected from pipework corrosion. One of the crystal types resembled sapphire and might be responsible for the valve failure found in this and other loops. (auth)

58171 HIGH-TEMPERATURE OXIDATION OF SOME OXIDATION-RESISTANT COPPER-BASED ALLOYS. Sanderson, M. D.; Scully, J. C. (Univ. of Leeds, Eng.). Oxidation Metals; 3: No. 1, 59-90(Jan 1971).

The oxidation behavior of Cu−2Be, Cu−5Al, Cu−8Al, Cu−3Si, Cu−2Al−2Si, Cu−2.5 Al−2.5 Si, Cu−4.5 Al−2Si, Cu−7.5 Al−2Si, Cu−6.5 Al−4Si, and Cu−4.5 Al−5Si, in the temperature range 100 to 800°C, in air, has been investigated by gravimetric measurements and by electron microscopical examination of stripped oxide films. Most of the alloys showed considerable resistance to oxidation. This was given mainly by a thermally grown film of γ-alumina on the Cu−Al and Cu−Al−Si alloys and by a beryllia film on the Cu−Be alloy. Other oxide phases, principally copper oxides, were also found to grow on the alloys and these are described. Silicon additions to Cu−Al alloys are found to improve their oxidation resistance, although no crystalline oxides containing silicon were observed in the oxide films stripped from the Cu−Al−Si alloys. (auth)

58172 OXIDATION OF NIOBIUM CONTAINING OXYGEN. Dekanenko, V. M.; Kornilov, I. I.; Vavilova, V. V. Izv. Akad. Nauk SSSR, Metal.; No. 6, 218-21(Nov-Dec 1970). (In Russian).

The oxidation resistance of Nb samples already containing O in solution was studied. Alloys of Nb containing O up to 5 at. % in the cast state exhibited a much greater oxidation resistance than pure Nb. Annealing at 300°C reduced the oxidation resistance, although it still remained higher than that of pure Nb. Alloys of Nb with O lying within the two-phase region, however, had a low oxidation resistance of 400°C; annealing these alloys sharply increased their rate of oxidation. The mechanisms responsible for these effects are discussed. (Metal Abstr.)

58173 SURFACE NITRIDING OF ZIRCONIUM. Samsonov, G. V.; Kaplina, G. S. Izv. Akad. Nauk SSSR, Metal.; No. 6, 222-5 (Nov-Dec 1970). (In Russian).

The surface nitriding of metallic Zr in a commercial N atmosphere cleaned of O and moisture (resultant O content 0.010 to 0.011%) was studied and the results were compared with those obtained for high-purity N. On treating in commercial N, the thickness of the nitride layers was much greater than in high-purity N, apparently as a result of the presence of oxides formed (these facilitated the diffusion of N into the growing layers of nitride). The activation energy for the diffusion on N into α-Zr was 49.7 kcal/mole in high-purity N and very slightly less in commercial N. (Metals Abstr.)

58174 METALLOGRAPHY OF THE 300 SERIES STAINLESS STEELS EXPOSED TO HIGH TEMPERATURE SODIUM. Miller, R. L.; Schrock, S. L.; Whitlow, G. A. (Westinghouse Advanced Reactors Div., Madison, Pa.). pp 105-14 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

Chemical and metallurgical changes in the austenitic Types 304 and 316 stainless steels exposed to a high temperature, dynamic, corrosive sodium environment were investigated as part of the commercial Liquid Metal Fast Breeder Reactor (LMFBR) development program. Utilizing small, pumped-sodium loop systems, which are corrosion mockups of the reactor circuits, the formation and subsequent growth of surface depleted zones, intergranular corrosion, and elemental mass transfer in austenitic stainless steels have been monitored as a function of exposure time. Evaluation has included both optical and scanning electron microscopy, x-ray diffraction, and microprobe analysis together with a chemical milling technique. The formation of iron rich surfaces on Type 316 stainless steel and the deposition of chromium, nickel, and manganese on Type 304 stainless steel sodium-exposed surfaces have been observed metallographically. These effects are discussed in relation to their occurrence in a low oxygen (<10 ppM), flowing sodium system operating at a maximum temperature of 1325°F. (auth)

58175 KINETICS OF ZIRCONIUM OXIDATION UNDER LOW OXYGEN PRESSURES. Dechamps, M. (CNRS, Vitry-sur-Seine, France); Lehr, P.; Debuigne, J. Mem. Sci. Rev. Met.; 68: No. 4, 267-75(Apr 1971). (In French).

The study of zirconium oxidation under a low oxygen pressure by thermogravimetry revealed that the parabolic oxidation kinetics is always preceded by a short period of oxidation with linear kinetics. The mathematical interpretation given (constant rate diffusion in a semi-infinite medium) takes the duration of the linear kinetics into account. (France)

58176 WELDABILITY AND CORROSION RESISTANCE OF TITANIUM–5 PERCENT TANTALUM ALLOY. Blashchuk, V. E.; Gurevich, S. M.; Zotova, L. M.; (and others). Avtomat. Svarka; No. 6, 16-18(Jun 1971). (In Russian).

The weldability of titanium alloy 4204, containing 5% Ta, was studied with 2.5 mm stock with which seam welds had been formed with automatic argon-arc equipment. The joints were found to be satisfactory mechanically, and possessed good corrosion resistance under conditions of strain in 18% HCl at 90°C containing some free chlorine. (K.S.W.)

58177 ANODIC DISSOLUTION OF HARD ALLOYS OF THE VK TYPE [TUNGSTEN CARBIDE–COBALT] IN ALKALI–NITRATE ELECTROLYTES. Parshutin, V. V.; Petrov, Yu. N.; Loskutov, A. I. Elektron. Obrab. Mater.; No. 3, 15-20(1970). (In Russian).

The anodic dissolution of W, WC, Co, and various WC−Co alloys in an NaOH−$NaNO_3$ electrolyte was studied, and the results were compared with those obtained for the components of the electrolyte individually. The polarization curves had quite different characteristics in the different electrolytes. High potentials existing in the case of the dissolution of WC−Co alloys in $NaNO_3$, for example, were attributed to the formation of a dense oxide film impeding dissolution. In appropriately mixed solutions a state could be achieved in which both components of the alloys dissolved uniformly. (Metals Abstr.)

Preparation and Fabrication

58178 (AWRE-O-42/71) PREFERENTIAL DEPOSITION OF THIN SILVER FILMS INDUCED BY ELECTRON BOMBARDMENT. Stroud, P. T. (Atomic Weapons Research Establishment, Aldermaston (England)). Aug 1971. 12p. Dep. NTIS (U. S. Sales Only). UK 10p.

Deposition of silver on silica or freshly evaporated silicon monoxide is described. Electron bombardment induces the preferential deposition of silver on pure fused silica but the reverse effect is noted with evaporated silicon monoxide. Attempts are made to explain these phenomena. (auth)

58179 (CONF-711002–, pp 47-58) SAMPLE PREPARATION BY METALLURGICAL METHODS. Van Audenhove, J.; Joyeux, J. (European Atomic Energy Community, Geel (Belgium). Central Nuclear Measurements Bureau). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Methods of preparing reference alloys for research centers and industries are described. Preparation techniques such as melting, shaping, canning, electrolysis, powder metallurgy, thermal reduction, and thermal treatments are described. (J.R.D.)

58180 (CONF-711002–, pp 70-6) MANUFACTURE OF CLAD FISSIONABLE FOILS FOR ZPR MEASUREMENTS. Hins, Allan G. (Argonne National Lab., Ill.). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Fabrication processes for homogeneous foil-type actinide fuel materials produced by high-precision methods are described. The fuels are contained in leaktight cladding which is corrosion resistant and tolerant of extensive handling. (J.R.D.)

58181 (CONF-711002–, pp 77-81) PREPARATION OF POWDER SAMPLES. Verdingh, V. (European Atomic Energy Community, Geel (Belgium). Central Nuclear Measurements Bureau). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Preparation methods for powder samples are described including compaction, direct pressing, and sedimentation. Aspects of sample canning processes are discussed along with methods of preserving purity. (J.R.D.)

58182 (CONF-711002–, pp 122-33) PREPARATION OF STANDARD LAYERS BY VACUUM EVAPORATION. Eschbach, H. L. (European Atomic Energy Community, Geel (Belgium). Central Nuclear Measurements Bureau). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

XUM

Methods used for preparing boron and lithium standard layers and some experimental results are discussed. Preparation methods for metallic uranium foils are discussed since their preparation and subsequent definition (together with other samples) are required for exact determination of the half-life of ^{234}U. Much the same care and precaution are involved as with the neutron flux standards. (auth)

58183 (CONF-711002–, pp 160-5) PREPARATION OF LAYERS BY ELECTROSPRAYING AND ELECTROPHORESIS. Verdingh, V. (European Atomic Energy Community, Geel (Belgium). Central Nuclear Measurements Bureau). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Preparation and definition of samples is one of the objectives of the Central Bureau for Nuclear Measurements. The requirements for such samples depend upon the kind of nuclear measurements to be done. In general, samples in film form must be homogeneous, adherent to the backing (if there is one) and stable over a long time. Thickness, surface area, and substrate are determined by the type of experiment; these factors together with the nature of the isotope and the quantity of starting material available largely influences the choice of the preparation method and the accuracy to which the layer can be defined. (auth)

58184 (CONF-711002–, pp 181-90) PRODUCTION AND CRYSTAL GROWTH OF ISOTOPIC RARE-EARTH METALS. Reed, R. E.; Grisham, W. B. (Oak Ridge National Lab., Tenn.). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

Single crystals of the rare-earth metal isotopes ^{154}Sm, ^{163}Dy, and ^{170}Er were obtained by grain growth annealing. Crystals as large as 2.5 × 2.5 × 0.5 cm are obtainable. The purity of the starting material was very important for appreciable grain boundary migration. The impurities carbon, oxygen, nitrogen, and hydrogen had to be <500 wt ppM for best results. The presence of precipitates greatly hindered grain growth. Use of argon-filled tantalum cans for containment and as a susceptor during induction heating provided a high-pressure atmosphere during annealing and prevented loss of valuable metal isotopes. Annealing times of about 100 hr were sufficient to achieve the major part of possible grain growth. The highest annealing temperature possible without going above solid state phase transformations or melting temperatures was most effective in obtaining large grain sizes. Observations made during this study suggest that the crystals were obtained by normal grain growth. (auth)

58185 (ORNL-TM-3499) EXPERIMENTAL INVESTIGATION OF FABRICATION OF Th-20 WT. PERCENT U FOR THE UMBR FUEL ELEMENT. Copeland, G. L.; Queener, L.; Martin, W. R. (Oak Ridge National Lab., Tenn.). Oct 1971. Contract W-7405-eng-26. 25p. Dep. NTIS.

Results are presented of an experimental investigation designed to determine the feasibility of fabricating a Th–20 wt % U hexagonal fuel element containing hexagonal coolant channels for the Unclad Metal Breeder Reactor (UMBR). Component parts from which the fuel element may be assembled can be produced by casting or by forming from an ingot. The most attractive method of fabrication appears to be forming component parts of the element from an ingot using conventional metalworking techniques. The ingots may be produced by consumable electrode arc melting or by consolidation of blended thorium and uranium powders. (auth)

58186 (ORNL-TM-3500) TUBING FABRICATION PARAMETERS AND THEIR APPLICATION TO TEXTURE CONTROL IN ZIRCALOY TUBING. Hobson, D. O. (Oak Ridge National Lab., Tenn.). Oct 1971. Contract W-7405-eng-26. 43p. Dep. NTIS.

Tubing fabrication involves combinations of strains imposed upon the material to effect required dimensional changes. These strains were analyzed from the standpoint of type of fabrication operation and have produced a graphical method for plotting fabrication paths. Such a method is applicable to operations, such as tube reducing, in which the inside surface dimension of the tubing is controlled throughout the fabrication step. Other operations, such as rod-mandrel drawing, required additional analysis of the true strains involved. Texture formation in Zircaloy tubing is dependent upon the ratio of true wall thickness strain to true circumferential strain at any point in the tube wall. The texture formation was characterized with fabrication parameters and showed how texture control can be achieved with all common fabrication processes. (auth)

58187 (SCL-T-710281) POSSIBLE USES OF PLASMA IN POWDER METALLURGY, WITH PARTICULAR REFERENCE TO SPHEROIDIZATION. Rutkowski, Wladyslaw; Szteke, Witold (Institute of Nuclear Research, Warsaw (Poland)). Translated for Sandia Labs., Livermore, Calif., from report INR-938. 43p. Dep. NTIS.

A discussion is presented on aspects of applying plasma in powder-metallurgical processes, application of powders to other processes with the use of plasma, and the application of other products of powder metallurgy in plasma processes. Results obtained with the spheroidization of Al_2O_3, Ta, and Ni powders are presented, as are the results of metallographic and microscopic investigations on these powders. (auth)

58188 (ZJE-110) SOME REMARKS CONCERNING ZIRCONIUM ALLOY WELDING. Sika, J. (Skoda Works, Pilsen (Czechoslovakia). Nuclear Power Construction Dept.). 1971. 20p. Dep. NTIS (U. S. Sales Only).

Aspects of zirconium alloy welding directed especially toward shielded welding using the TIG-method or electron beam welding are examined. Experimental welding results are given which have been achieved first on substitute materials and afterwards mainly on the C2M zirconium alloy up to a thickness of 1 mm. A brief description of the welding equipment, protection chamber with preliminary vacuum treatment, the ES-2 electron welding machine is given which indicates the possibilities of welding fuel element cans from zirconium alloy. (auth)

58189 KINETICS OF THE REDUCTION OF TUNGSTEN AND MOLYBDENUM TRIOXIDES BY HYDROGEN. Chizhikov, D. M.; Rather, Yu. E.; Tsvetkov, Yu. B. Izv. Akad. Nauk SSSR, Metal.; No. 6, 8-13(Nov-Dec 1970). (In Russian).

The reduction processes of tungsten and molybdenum trioxides proceed in stages with the formation of a series of intermediate products. Stages in the processes are confirmed by studies of the electric conductivity of the restored oxide phases. The presence of water in the gas phase has different effects on the kinetics of the reduction processes for the trioxides of tungsten and molybdenum. The increase in the ratio $H_2O:H_2$ in the gas phase accelerates the reduction process for tungsten trioxide and slows down the process for MoO_3. On the reduction of WO_3 by hydrogen with increased water content in the gas phase, metallic tungsten powder particles expand. The presence of water vapor in the gas phase has no pronounced effect on the coarseness of metallic Mo powder produced by the reduction of MO_3. (tr-auth)

58190 ETCHING OF METALLOGRAPHIC SPECIMENS BY CAVITATION. Young, Stanley G. (Lewis Research Center, Cleveland). pp 167-85 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

A vibratory technique employing a magnetostrictive transducer was used to determine the cavitation damage in distilled water to several unalloyed metals and one nickel-base superalloy at room temperature. Some of the unalloyed metals studied were too soft to withstand the forces generated within a specimen when it was ultrasonically vibrated. Therefore, a technique was used in which the specimens were held stationary beneath an ultrasonically vibrated head, and cavitation damage was caused to the specimen by a cavitating cloud formed between the vibrating head and the stationary specimen. The specimens were polished metallographically before testing and examined at several time intervals during tests. Preferential damage at grain boundaries and other metallurgical features were observed in the unalloyed metals as a result of cavitation attack. Structural features of the complex alloy, Udimet 700, were clearly revealed. The results indicate that cavitation may be useful as a technique for selective etching of materials. The weaker phases would be removed, leaving the tougher, harder, impact resistant phases. This method would also allow the investigator to easily recover material from the distilled water (or any other fluid desired) for further analysis without the disadvantages associated with the use of reactive chemicals. (auth)

58191 URANIUM INDUSTRY WITH REALISTIC CONCEPTS OF CONSUMPTION. Guenzel, H.; Knoerr, B. K. Metall; 25: No. 7, 825-8(Jul 1971). (In German).

Recent developments, especially during the last two years, demonstrate that a free economy rapidly develops new markets, and finds means for discovery and utilization of necessary material. This fact is evidenced by the finding of significant uranium depisits. In the future, the cost of U_3O_8 will be determined more than previously by the mineral content of the accessible ore. Also, the interest will turn toward other fuel cycles, such as thorium, and, thereby, create competition between raw materials for nuclear energy. Safe predictions are premature because of the many technical problems that still await solution. (tr-auth)

58192 PURIFICATION OF VANADIUM AND PRODUCTION OF VANADIUM SINGLE CRYSTALS THROUGH ZONE MELTING. Bressers, J. (Kommission der Europaeische Gemeinschaften Gemeinsame Forschungsstelle Forschungsanstalt, Petten, Netherlands); Heerschap, M.; De Meester, P. Metall; 25: No. 7, 765-9(Jul 1971). (In German).

A zone melting method is described which permits purification of vanadium as well as production of oriented single crystals. A technique is also described for tensile testing of the single crystals by the melting of spherical heads on the crystals. An analysis of interstitial impurities reveals that zone melting strongly reduces the oxygen content. Carbon content decreases not as strikingly, and nitrogen content remains constant. The degree of purity of the obtained vanadium is established by determination of rigidity, specific electric resistance, and other flux measurements. (tr-auth)

58193 ELECTRIC-EROSION MACHINING OF DEEP CYLINDRICAL APERTURES [IN METAL PARTS]. Foteev, N. K. Elektron. Obrab. Mater.; No. 3, 9-15(1970). (In Russian).

The conditions required for machining deep cylindrical apertures up to 10 mm in dia with a depth/dia ratio of 10 to 250 by the electric-erosion method in metal parts (Mo, Nb, heat-resistant Ni alloys) are discussed in the light of practical experience. Some particular metallographic analyses of apertures drilled by this method in these metals are presented. Practical recommendations are made for optimizing the machining process. (Metals Abstr.)

58194 CONSTRUCTIONAL COMPONENTS FOR THE REACTOR CORE IN NUCLEAR POWER GENERATION. Kobe Seiko Giho; 20: No. 2, 66-9(Apr 1970). (In Japanese).

Kobe Steel Ltd. has engaged in the technology development for construction of the nuclear power-generation reactor core components. These include a channel box of BWR plants which is used to regulate coolant flow and is made of Zircaloy-4. The procedure of its manufacture is by bending the plate in the form of a U and subsequent welding. Stainless steel cladding tubes for nuclear-powered ships are described including the chemical composition, tensile properties, and dimensions required. Stainless steel cladding tubes for AGR's are also described. Pressure tubes and calandria tubes for the ATR are being developed in Japan composed of Zr/2.5% Nb alloy and Zircaloy-2, respectively. Stainless steel cladding tubes, wrapped with wire to ensure efficiency of the cooling channels and wrapper tubes to maintain the fuel spacing, for the FBR are being developed which are made of AISI 316 stainless steel. (Japan)

58195 LUBRICATION ASPECTS OF THE DEEP DRAWING OF STAINLESS STEEL, TITANIUM, AND NICKEL-BASE ALLOYS AT ELEVATED TEMPERATURES. Pope, Malcolm H.; Robins, Leonard; Berry, John T. ASLE (Amer. Soc. Lubric. Eng.) Trans.; 13: No. 2, 148-58(Apr 1970).

A range of potential lubricants was examined in friction and actual cup-forming tests on AISI 304, Inconel X and Ti−6Al−4V. Among these potential lubricants were boron nitride, two graphitic materials and two oxides of Mo. The latter two materials appear to be promising at temperatures above 900°F. Further development work is being undertaken. (Metals Abstr.)

58196 MILLING [OF A SPECIMEN] SURFACE HARDENED BY A CHROMIUM–TUNGSTEN WIRE [HARD-FACING PROCESS]. Kaganovich, D. I. Stanki Instrum.; No. 9, 41-2(Sep 1970). (In Russian).

A surfacing process using fused Cr−W wire is widely used to improve the heat-resistant and wear-resistant properties of metallurgical plant equipment. The surface layer containing C 0.3, Cr 2.5 to 3.0, W 8.5 to 10.0, Mn 1.0, and V 0.3% is difficult to machine. VK-group alloy cutting tools are usually used. Productivity can be improved by pre-heating the surface to a relatively low temperature (100 to 150°C) both for machining and milling. (Metals Abstr.)

58197 HOT ISOSTATIC PRESSING. Johansson, R.; Isaksson, S.-E. Powder Met. Int.; 2: No. 2, 49-50(Jun 1970).

Manufacture of high-speed tool steels and tungsten carbides by means of hot isostatic pressing is described. The conventionally made high-speed tool steel shows a great tendency toward segregation and irregular coarse-grained structure. By manufacturing high-speed tool steel out of powder, a material with a very fine structure is achieved. The carbide grain size is 1 μm or smaller and segregations are eliminated. Hot isostatic pressing has increased the life of high-speed tool-steel drills by 400%. Tungsten carbide is a dense material but often contains pinholes that reduce the tensile strength. A reduction of pinhole volume led to an increase in the life of certain types of high-pressure dies. (Metals Abstr.)

58198 MILLING [CHARACTERISTICS] OF A HIGH-TEMPERATURE NIOBIUM ALLOY. Ivanov, A. P.; Dryakina, I. P. Stanki Instrum.; No. 6, 40-1(Jun 1970). (In Russian).

Although Nb-base alloys have a range of valuable constructional properties and belong to a group of materials with a promising future, they are not widely used owing to the sparse nature of published information concerning their technical characteristics and mechinability. Investigations were therefore carried out into the milling of a typical high-temperature Nb-base alloy, VN-3. This is a Nb−Mo−Zr alloy containing nitride, carbide, oxide, and hydride inclusions dispersed in the grains and grain boundaries; UTS = 70 to 80 kg/mm^2. Experiments were carried out on flat, 80 × 8 mm specimens with a cutting tool of R18 steel. Temperature measurements were made by the natural thermocouple method (cutting tool/workpiece) and recorded on an oscillograph. The dynamics and temperature of milling were studied over a wide range of cutting speed, feed, and depth of cut and the results presented in a series of graphs. Experiments were also carried out at −196°C in liquid N. (Metals Abstr.)

58199 METALWORKING. Olofson, C. T.; Byrer, T. G.; Boulger, F. W. (Battelle Memorial Inst., Columbus, Ohio). DMIC Rev.; 4p.(12 Aug 1970).

A report is given on two programs to develop manufacturing processes for dispersion-strengthened alloys; one is concerned with fabricating TD Ni−Cr tubing to sizes of 0.3125-in. OD × 0.035-in. wall, 0.25-in. OD × 0.020-in. wall and 0.156-in. OD × 0.020-in. wall; the other is to develop sheet-fabrication practices for TD Co−Ni−Cr alloys in thicknesses of 0.075, 0.050, and 0.020 in. Other studies include the use of molten A-47 glass for heat treating forging stock of Ti−6Al−6V−2Sn alloy and 4340 alloy steel; rolling of tapered Ti−6Al−4V alloy plate; and fabrication of 0.005-in. dia Be wire and thin-wall Ti−6Al−4V alloy tubes by hydrostatic extrusion drawing. Metal-cutting studies include work on machining stainless steel, mild steel and pure Ti at cryogenic temperature, finish machining of medium-C steels in O, N, and Ar atmospheres and effects of Al and S contents on the tool life in the screw machining of Type 303 stainless steel. (Metals Abstr.)

58200 ACTIVATED SINTERING. Barta, J. Powder Met. Int.; 2: No. 2, 52-4; 56-7(Jun 1970).

"Activated sintering" would involve physical or chemical changes related to the sintering material which would cause a significant decrease in sintering time and/or temperature as compared with a known procedure. Theories of sintering are considered and it is shown that to increase sintering rates, that is, to "activate" sintering, it is necessary to increase the driving forces for sintering and to decrease the resistance to material transport. Experimental data are presented for Ni, MgO, W, and others to substantiate theories of activated sintering. It is concluded that the available theories and basic data do not allow an unequivocal evaluation of the experimental data. Furthermore, it is shown that "activated sintering" might be meaningful only within a technological frame of reference; theoretically, "activated sintering" is sintering carried out at selected values of sintering parameters and is, in principle, not different from ordinary sintering. (Metals Abstr.)

58201 JOIN EXOTIC MATERIALS IN SECONDS WITH CONTINUOUS SEAM DIFFUSION BONDING. Metcalte, Arthur G.; Goad, Robert C. Machinery (N. Y.); 76: No. 15, 54-7(Nov 1970).

Continuous seam diffusion bonding can continuously and quickly join Ti, Ti alloys, Hastelloy X, 17-4PH stainless steel, TD-NiC, Nb alloys, and other high-strength materials without using an intermediate layer or requiring caskets, filler blocks, and heating furnaces. The bonding machine is equipped with opposed hot rotating wheels that are adjustable for height, temperature, and drive speed. High-strength joints are produced in complex shapes or laminated parts. (Metals Abstr.)

58202 OPEN ALUMINOTHERMIC REDUCTION OF COLUMBIUM (Nb) PENTOXIDE AND PURIFICATION OF THE REDUCED METAL. Kamat, G. R.; Gupta, C. K. (Bhabha Atomic Research Centre, Trombay, India). Met. Trans.; 2: No. 10, 2817-23(Oct 1971).

This investigation is concerned with the extraction of Nb metal by aluminothermic reduction of its pentoxide in a refractory-lined open reactor. Reduction with 15% of aluminum in excess of stoichiometric and priming at the center are found to be optimum parameters. Trials with 3-kg batches of niobium oxide have resulted in high yields of consolidated Nb. Aluminum-reduced Nb has been

XUM

further processed by electron-beam melting—after prior pyrovacuum treatment for removal of aluminum, and also directly—and in either case it has been possible to produce pure and ductile Nb. The investigation proceeds to evaluate fused salt electrorefining of the reduced Nb employing $NaCl-KCl-K_2NbF_7$ bath. Conditions for operating the cell at 90% or more current efficiency have been established. Electrorefining has been found to be effective in lowering of most of the impurities in the anode feed. Electrolytic Nb on consolidation by electron-beam melting is found to have a hardness value of 50 Dph. (auth)

58203 NICKEL- AND COBALT-BASE ALLOYS. Simmons, W. F.; Beuhring, V. F. (Battelle Memorial Inst., Columbus, Ohio). DMIC Rev.; 5p.(17 Jul 1970).

Recent research on Ni and Co alloys includes work on: cast Ni superalloys containing Re, Mn, Y, Ce, Gd, Th, and La to improve oxidation and hot corrosion resistance; a turbine-blade casting alloy containing Cr, Al, W, and Mo for optimum properties in thin sections; high-temperature compressive yield strengths and hot hardnesses of heat-resistant Co and Ni alloys; mechanisms used to strengthen Ni-base superalloys; turbine-vane applications for the thoria-containing alloys $Co-20Ni-18Cr-2ThO_2$ and $Co-20\,Ni-30Cr-2ThO_2$; effect of very low-S levels in fuel on the hot corrosion of turbine-blade alloys; effect of different Cr: Al ratios on the oxidation in air or O of Ni alloys at 800 to 1300°C; oxidation resistance of WI-52 and IN-100 superalloys in static air at 1500 to 2000°F; and oxidation resistance of Co superalloys WI-52 coated with a commercial aluminide coating. (Metals Abstr.)

58204 SIGNIFICANCE AND USE OF INTERMEDIATE LAYERS DURING WELDING AND METAL SPRAYING [OF DISSIMILAR METALS]. Wirtz, Heribert. Schweissen Schneiden; 22: No. 10, 417-21(Oct 1970). (In German).

The requirements and properties of intermediate layers, which are used when joining and coating dissimilar metals are discussed. For example, when welding pure Cu to mild steel or low-alloy steel, a 2- to 5-mm-thick intermediate layer of weld deposit S-NiCr-15Fe-10Nb is provided. Materials used for intermediate layers when joining steel to various alloys e.g., Cu–Zn, Cu–Sn, Cu–Si, Cu–Al, Cu–Ni, are described and also steel to Al. Steel clad with X 10 CrNiTi 18 9, and lamellar-graphite cast-iron weldments are also considered. Satisfactory joints between dissimilar metals can be achieved if the instructions given (with regard to the intermediate layer) are carried out both during manufacture and repair welding. (Metals Abstr.)

58205 SPECIAL WELDING PROBLEMS MET DURING THE MANUFACTURE OF FUEL ELEMENTS FOR THE SUPERHEATED-STEAM REACTOR AT GROSSWELZHEIM. Zutz, Lothar; Busch, Herbert. Schweissen Schneiden; 22: No. 11, 461-4(Nov 1970). (In German).

The fuel element and fuel element components of superheated-steam reactors (HDR) are described and brief details are given of the various types of welding operations involved in their manufacture e.g., TIG, electron-beam welding, various soldering techniques and tube cladding e.g., with Zircaloy-2 on Cr–Ni steel or vice versa. The main material used in fuel element manufacture is Inconel 625 and the welding-fabrication, nondestructive and destructive testing techniques used are described. A special TIG-welding machine enables the welding parameters to be controlled since extra care must be taken during welding because of the high degree of loading to which fuel-element components are subjected. (Metals Abstr.)

58206 TUNGSTEN NEWS, AUGUST 1971. Tungsten News; 1-18(Aug 1971).

Activities associated with manufacture and use of W are reviewed. Information is included on the agenda of a metallurgy seminar, properties and uses of W, properties and uses of WC, properties and uses of W-base alloys, processing of W ore concentrates, and properties of W compounds. 300 references are included. (J.R.D.)

58207 DIFFUSION BONDING: METHODS AND APPLICATIONS. III. METAL-JOINING PROBLEMS. Alm, Gerald V. Adhes. Age; 13: No. 9, 31-6(Sep 1970).

Difficult applications of diffusion bonding include: solid-state bonding of PbTe thermoelectric material in a nuclear reactor to a series of metals and alloys such as Cu, Fe, Al, and 62Ag–24Cu–14In; joining of intricately finned Al extrusions to the OD and ID surfaces of U alloy fuel tubes; diffusion bonding of Al cold plates and thermal conditioning panels for the Apollo and Saturn launch vehicle; bonding of Al/stainless steel tubular transition joints; diffusion bonding of 0.006-in. thick Al foil to a 21-in. dia piston wall of 6061 Al alloy; diffusion bonding of a Ti–6Al–4V alloy bellows and roll bonding of clad nuclear-reactor fuel elements and corrugated-core aerospace structures. A table lists advantages and limitations for joints between broad, flat surfaces, tube and bar butt joints, line contacts, and interfaces between tubes. (Metals Abstr.)

58208 (AECL–3967) DIFFUSION COEFFICIENT AS A GUIDE TO PROSPECTS FOR HIGH-TEMPERATURE ZIRCONIUM ALLOYS. Carpenter, G. J. C. (Atomic Energy of Canada Ltd., Chalk River (Ontario). Chalk River Nuclear Labs.). Jun 1971. 30p. Dep. NTIS (U. S. Sales Only). AECL $1.00.

The high-temperature creep deformation of metals and alloys was reviewed in an effort to obtain a perspective on prospects for high-temperature zirconium alloy development. It was concluded that the most important factor that limits resistance to stress at high temperatures is the rate of self-diffusion. This is more important than other fundamental physical properties of zirconium involved in deformation, namely the elastic modulus and the stacking fault energy. Since it is possible, in principle, to include similar obstacles to dislocation motion in any metal, the self-diffusion coefficient can be used as a guide to the high-temperature potential for zirconium. On this basis, α-zirconium appears to behave as if it had an effective melting point of about 1500°C. This is close to a value calculated by A. J. Ardell (Acta Met., 11, 591 (1963)) from thermodynamic considerations. It is suggested that a rough guide to the long term development prospects for dilute zirconium alloys based on conventional alloying techniques can be obtained by looking at the creep properties of the low alloy ferritic steels. These steels are available with a creep rate of $\sim 10^{-7}$/hour under a stress of 10,000 psi at temperatures up to 600°C. (auth)

58210 (IS-T–490) CAPILLARY-RESERVOIR DIFFUSION STUDIES IN Hg–In ALLOYS UTILIZING CONTINUOUS RESISTIVITY MEASUREMENT OF COMPOSITION. Kaiser, Robert Hamilton (Ames Lab., Iowa). Sep 1971. Contract W-7405-eng-82. 95p. Dep. NTIS.

Thesis.

A capillary-reservoir diffusion cell has been designed to follow the process of liquid metal diffusion in the capillary on a continuous basis. Molybdenum electrodes were located at intervals along the capillary so that the composition could be monitored by noting the change in resistivity of the capillary contents. These probes were in the form of annuli with respect to the capillary which enabled the measurement of resistances without obstructing the diffusion process. This cell was used to measure the composition dependence on the diffusion coefficient in the mercury-indium system at 25°C. Compositions up to 13.19 at. % indium were investigated. The summary equations relating composition in atomic fraction indium and diffusivity in cm²/sec for two capillary sections are as follows: Section 2 $D = 3.00 \times 10^{-5}\,\overline{N} + 1.48 \times 10^{-5}$, Section 3 $D = 2.80 \times 10^{-5}\,\overline{N} + 1.30 \times 10^{-5}$. When compared with previous data on indium amalgams, the results indicate that the technique is adequate. (auth)

58211 (LA–4758) THERMODYNAMIC PROPERTIES OF $PuRu_2$ FROM EMF MEASUREMENTS. Campbell, George M. (Los Alamos Scientific Lab., N. Mex.). Sep 1971. Contract W-7405-eng-36. 4p. Dep. NTIS.

Non-stationary emf techniques were used to ensure reversibility and singularity of electrode reactions in the emf cell $Pu(l)/PuCl_3$, $LiCl-KCl/PuRu_2 + Ru(s)$ at temperatures between 913 and 1078°K. The free energy of formation of $PuRu_2$ at 1000°K was found to be $\Delta G_{f1000} = -8.08 + 0.0013$ T kcal/mole. Thermodynamic properties were estimated at lower temperatures. (auth)

58212 (NRCN–268) A STUDY ON DIFFUSION OF Co IN Pu. Daft, M. (Israel Atomic Energy Commission, Beersheba. Nuclear Research Center-Negev). Aug 1970. 153p. (In Hebrew). INIS.

As plutonium is used widely as a fuel, it is important to study its properties at high temperature. Many of the processes in these conditions are diffusion mechanisms. The solute was ^{60}Co, and the problems of vaporizing it are discussed. Some experiments were carried on γ-uranium and β-uranium and gave results that corresponded to those in the literature, and this proved that the methods used were suitable. The experiments were carried on: ϵ-plutonium at 506°C, delta phase Pu at 340°C to 400°C, δ phase Pu–9% Al alloy and ϵ-gold-198–Pu alloy. (INIS)

58213 (ORNL-TM–3350) STUDY OF THE FORMATION OF CREEP CAVITIES IN POWDER-METALLURGY TUNGSTEN. Stiegler, James O. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 200p. Dep. NTIS.

Thesis. Submitted to Univ. of Tennessee, Knoxville.

At elevated temperatures metals suffer a loss in ductility brought about by the formation of grain-boundary cracks. Details of the nucleation and growth of these cracks in tungsten produced by a powder-metallurgy process were studied by electron fractography. Creep tests were interrupted and the specimens fractured at room temperature to expose any cavities or cracks formed at high temperatures for examination. After an annealing treatment of one hour at 1600°C the grain boundaries of the tungsten were populated by about 10^7 gas bubbles per square centimeter averaging approximately 0.2 μm in diameter. The bubbles were distributed nonrandomly, and there were large variations in bubble size and distribution. Different grades of tungsten showed different grain-boundary structures. Under stress at 1600°C these bubbles expanded. At low stresses they grew slowly and maintained equiaxed, crystallographic shapes. At high stresses they grew rapidly in the plane of the grain boundary and formed irregular, flat cavities about 1 μm thick. These cavities tended to grow rapidly in certain directions but always with blunt ends. No evidence of cavities nucleated by deformation was obtained, but a few rare cases of possible triple-grain junction cracks were found. Only a slight tendency for spheroidization of the flat cavities was noted for annealing times as long as 100 hours at 1600°C. The model most in agreement with these observations is one in which the gas bubbles expand to form the cavities by the stress directed diffusion of vacancies along the grain boundaries. At low stresses this occurs slowly enough that the cavities are able to maintain equiaxed shapes by the process of surface diffusion. When the growth rate exceeds some critical value, surface diffusion no longer can occur rapidly enough, and the cavities grow in the plane of the boundary. Their irregular shapes suggest that the average stress does not direct their growth but that local variations in stress possibly resulting from grain-boundary sliding or deformation within the grains are responsible. The wedge-like cracks observed with the optical microscope arise when the flat cavities reach a triple-grain junction and are opened into a wedge by sliding on the adjacent grain boundaries. This model reconciles the conflicts in some of the previous models for crack formation. Since the specimen elongates as the cavities expand, their growth constitutes a creep mechanism. The creep rate from the diffusion-controlled growth of equiaxed cavities is in order-of-magnitude agreement with measured creep rates for materials containing cavities. The creep rate from growth of cavities in the concentrations present in the powder-metallurgy material used in this work is about two orders of magnitude faster than Nabarro–Herring diffusional creep would occur in the same material. Some unusual observations made on a powder-metallurgy tungsten–25% rhenium alloy which deformed at a faster rate at 1650°C than at 2200°C at a stress of 500 psi are explained semiquantitatively by this model of creep due to cavity growth and the observed microstructural features. The characteristics of creep by cavity growth are also described. (auth)

58214 (RD/B/N–2023) NUCLEATION OF ATOMIC STEPS ON INERT GAS BUBBLES INTERSECTED BY DISLOCATIONS. Beere, W. (Central Electricity Generating Board, Berkeley (England). Berkeley Nuclear Labs.). Jun 1971. 18p. Dep. NTIS (U. S. Sales Only).

The diffusivities of small polyhedral bubbles attached to dislocations in copper thin foils were calculated from observations of the distances migrated and the rate of diffusion to the foil surface during isothermal annealing. It was shown that when few collisions occur between bubbles the bubble diffusivity could be easily calculated from the experimental data. The bubble diffusivities were satisfactorily described by a rate controlling nucleation mechanism, in which ledges, introduced into the bubble surface by the dislocation, rotated about the dislocation causing the bubble to migrate. The model predicted that bubbles intersected by dislocations would have higher diffusivities than bubbles in a perfect lattice. (auth)

58215 (Y-DA–4280) SCANNING ELECTRON MICROSCOPY OF FRACTURES IN WELDED STRUCTURES. Lundin, Carl D.; Bennett, Robert K. (Union Carbide Corp., Oak Ridge, Tenn. Y-12 Plant). 14 Sep 1971. Contract W-7405-eng-26. 19p. (CONF-710902–5). Dep. NTIS.

From fourth annual meeting of the International Metallographic Society; Denver, Colo. (21 Sep 1971).

The scanning electron microscope has been used to observe and characterize the morphology of the surfaces of weld defects, discontinuities, and fractures. These observations and characterizations have enabled the definition of the mechanism of formation of weld defects and have provided information as to the factors leading to the formation of weld fractures. In nickel-base alloys hot cracking is easily and clearly recognized by scanning electron fractography. In most cases a liquid film is an integral part of the cracking mechanism, and other evidence suggests that at times two liquid films of differing compositions and properties play a part in the mechanism of crack formation. Evidence is also available which suggests the possibility of a stress-rupture mechanism of hot crack formation in which a previously solidified film plays a role. In molybdenum and molybdenum base alloys, clear evidence has been obtained that the majority of hot crack formations during welding is influenced by liquid films. A second mechanism of elevated temperature fracture in these alloys has been determined to result from void formation on grain boundaries and link-up of voids to form microfissures and subsequent boundary fracture. (auth)

58216 (ZJE–106) DEVELOPMENT OF PRESSURE VESSEL STEELS FOR CZECHOSLOVAK NUCLEAR POWER STATIONS. Becka, J.; Brumovsky, M.; Filip, R.; Indra, J. (Skoda Works, Pilsen (Czechoslovakia). Nuclear Power Construction Dept.). 1971. 25p. Dep. NTIS (U. S. Sales Only).

The basic characteristics of five types of steels which were developed and studied for nuclear reactor pressure vessels are reviewed. Effect of initial size of defects on the initiation of brittle-fracture and of radiation damage are taken into account. (auth)

58217 (ZJE–107) PROPERTIES OF ZIRCONIUM ALLOYS FROM THE OPERATION STANDPOINT. Filip, R.; Velkoborsky, J. (Skoda Works, Pilsen (Czechoslovakia). Nuclear Power Construction Dept.). 1971. 20p. Dep. NTIS (U. S. Sales Only).

The selection of zirconium alloys for the active zone of the gas-cooled heavy water reactor is discussed along with classification and properties of these alloys from the technical standpoint. Information is given about the technique of zirconium alloys evaluation in relation to their creep and, furthermore, about specific properties of the experimental testing equipment. (auth)

58218 TENSILE AND IMPACT PROPERTIES OF THICK-SECTION PLATE AND WELDMENTS. Canonico, D. A.; Berggren, R. G. (Oak Ridge National Lab., Tenn.). Nucl. Eng. Des.; 17: No. 1, 4-15(1971).

Most nuclear pressure vessels have been fabricated from ASTM A533, grade B, class 1 steel plate. This steel is quenched and tempered in order to obtain its optimum properties in section sizes from 6 to 12 in. in thickness. The quench-and-temper heat treatment results in a variation in mechanical properties through the thickness of the plate. The room temperature ultimate tensile strength varies from nearly 97,000 psi at the plate surface to about 89,500 psi at the midsection ($\frac{1}{2}$ T). The greatest effect of the quench is observed in the nil ductility transition temperature. The 30 ft lb Charpy V-notch temperature varies from –150°F at the surface to +10°F at the $\frac{1}{8}$ T location. Anisotropy due to the rolling is reflected in the upper shelf values of the longitudinal, transverse, and through-the-thickness properties of the plate. These values are 115, 100, and 80 ft lb, respectively, for the three directions. Three welding processes are employed in the fabrication of the pressure vessels. These are the submerged arc (subarc) process, the shielded metal-arc process, and the electroslag process. The sub-

XUM

arc and shielded metal-arc processes employ multipass welding techniques and the weldments resulting from these processes are only stress relieved after welding. The electroslag weld consists of a coarse-grained (ingot-like) structure which is unacceptable in the as-welded condition. The electroslag weldment is quenched and tempered after welding. The ultimate tensile strength of the welds is uniform through their thicknesses. Their ultimate tensile strengths are all similar, about 80,000 to 85,000 psi. The impact properties of the electroslag and multipass weldments are not similar. The electroslag weld metal has an upper shelf Charpy V-notch energy of about 80 ft lb, whereas the multipass welds (subarc and shielded metal-arc) have shelf values of from 120 to 150 ft lb. Further, the 30 ft lb C_V temperature of the subarc and shielded metal-arc welds are near –50 to –70°F. The temperature for the electroslag weld metal for the same energy value is –20°F. (auth)

58219 TESTING THE SIX-INCH THICK FLAWED TENSILE SPECIMEN FOR THE HEAVY SECTION STEEL TECHNOLOGY PROGRAM. Grigory, Stephen C. (Southwest Research Inst., San Antonio, Tex.). Nucl. Eng. Des.; 17: No. 1, 161-9(1971).

The 15 million pound tensile test facility at Southwest Research Institute has been used to test a series of large tensile specimens for the Heavy Section Steel Technology (HSST) Program. These specimens are A533 grade B, class 1, and are 6 in. thick, 18 in. wide, 4 ft long and contain flaws. The procedures used to create the flaws are discussed and pertinent data for six tests at temperatures from 50°F to 220°F and requiring loads up to 7.5 million pounds for failure are presented. (auth)

58220 ACTIVITY OF ALUMINUM, VANADIUM, AND CHROMIUM IN BINARY TITANIUM ALLOYS. Rubtsov, A. N.; Olesov, Yu. G.; Cherkashin, V. I.; Suchkov, A. B. Izv. Akad. Nauk SSSR, Metal.; No. 6, 84-7(Nov-Dec 1970). (In Russian).

The activities of Al, V, and Cr in Ti–Al, Ti–Cr and Ti–V alloys subjected to successive hydrogenation and dehydrogenation for refining purposes were determined by the emf method and correlated with the activities of Ti in the corresponding materials. The activity of Ti was much greater in hydrogenated alloys. This effect was attributed to the rupture of the bonds between the Ti and the alloying elements. By taking advantage of this effect the removal of unwanted elements from Ti may be greatly facilitated. (Metals Abstr.)

58221 STUDY OF THE GAS EVOLUTION AND MECHANICAL PROPERTIES OF MOLYBDENUM WIRE. Nechiporenko, E. P.; Kirillov, V. S. Izv. Akad. Nauk SSSR, Metal.; No. 6, 128-34(Nov-Dec 1970). (In Russian).

The effect of annealing temperature and vacuum treatment on the mechanical properties of Mo wire and on the amount of gas evolved from the metal was studied. A 10-min vacuum anneal at 750 to 1500°C sharply reduced the yield strength and increased the ductility, the relative elongation after annealing at 1500°C being >50%. Anomalous grain growth occurred during annealing and the C content diminished; these effects were detrimental and favorable respectively towards the ductility. (Metals Abstr.)

58222 STUDY OF CREEP IN NIOBIUM–MOLYBDENUM ALLOYS. Prokoshkin, D. A.; Vasil'eva, E. V.; Tret'yakov, V. I. Izv. Akad. Nauk SSSR, Metal.; No. 6, 146-50(Nov-Dec 1970). (In Russian).

The creep characteristics of Nb–5 to 20 wt. % Mo alloys were studied at 1100 to 1300°C for stresses of 10 to 30 kg/mm^2. There was a regular decrease in creep velocity (steady creep section) with increasing Mo content, apparently as a result of a reduction in diffusion mobility. The velocity of steady creep varied with applied stress in accordance with a power relationship, the power index rising from 2.8 to 4.6 with increasing Mo content over the range studied. The activation energy for steady creep rose from the value corresponding to the self-diffusion of pure Nb to much higher values with increasing Mo content. (Metals Abstr.)

58223 STUDY OF HARDENING DURING THE FATIGUE OF VARIOUS PURE METALS [ALUMINUM, CADMIUM, ETC.]. Shetulov, D. I.; Magidov, M. B.; Myasnikov, A. M.; Shibarov, V. V.; Sokolov, L. D. Izv. Akad. Nauk SSSR, Metal.; No. 6, 165-9(Nov-Dec 1970). (In Russian).

Changes taking place in the strength, hardness, ductility, and microstructure of a number of metals (Al, Cd, Zn, Cu, Fe, and Ti) during fatigue (alternating stresses) were studied, the corresponding fatigue diagrams being plotted and correlated with structural changes. The slopes of the fatigue curves correlated directly with the stacking-fault energy of the corresponding materials (the higher the stacking-fault energy, the steeper the curve). This result is discussed in terms of hardening theory. (Metals Abstr.)

58224 HEAT RESISTANCE OF NICKEL-BASE ALLOYS. Ryabtsev, L. A.; Pryakhina, L. I.; Ignatov, D. V. Izv. Akad. Nauk SSSR, Metal.; No. 6, 190-1(Nov-Dec 1970). (In Russian).

The heat resistance of Ni–Al alloys of various compositions was studied. The heat resistance of the γ' solid solution, based on the chemical compound Ni_3Al (formed in alloys with a 14% Al content) was much greater than that of the γ solid solution (formed in alloys with 3% Al) due to the formation of spinel-like oxides on the surface. In two-phase alloys, the presence of the γ' phase made a major contribution to the over-all heat resistance. The introduction of Cr and Ti in addition to Al produced a further rise in heat resistance. (Metals Abstr.)

58225 THERMOPHYSICAL PROPERTIES OF YTTRIUM ABOVE 20^{0}C. Suganeev, Yu. S.; Taubin, M. L.; Yakutovich, M. V. Izv. Akad. Nauk SSSR, Metal.; No. 6, 215-17(Nov-Dec 1970). (In Russian).

The thermophysical properties of Y (thermal conductivity, thermal diffusivity, specific heat and electrical conductivity) were studied at 20 to 400°C. An empirical relationship was obtained for the specific heat at constant pressure: $294.3 + 1.59T - 3.3 \times 10^{-4}T$ J/kg°C, T being the absolute temperature. Both phonon and electron mechanisms made appreciable contributions to the thermal conductivity. The observed contribution of the phonon mechanism agreed in order of magnitude with the theoretical value. (Metals Abstr.)

58226 ADSORPTION OF OXYGEN ON THE BOUNDARIES (100) OF TUNGSTEN. Gorodetskii, D. A.; Mel'nik, Yu. P. (Kiev State Univ.). Izv. Akad. Nauk SSSR, Ser. Fiz.; 35: No. 5, 1064-9(May 1971). (In Russian).

The action of oxygen on the surface of tungsten was studied by two simultaneous methods: the diffraction of slow electrons, and the contact difference of potentials, which together yielded complete information on the O–W (100) system. The work function at the surface of W was determined as a function of the O adsorption time at room temperature. The change in the work function at the W surface with an O film present was measured during heating over the temperature range 20 to 1,000°C. (K.S.W.)

58227 EVAPORATION OF TUNGSTEN IN STRONG ELECTRIC FIELDS AS STIMULATED BY NITROGEN ADSORPTION. Mikhailovskii, I. M.; Sidorenko, N. N. (Physical-Technical Inst., Kharkov). Sov. Phys.-Solid State (Engl. Transl.); 13: No. 3, 680-3(Sep 1971).

Translated from Fiz. Tverd. Tela; 13: No. 3, 824-8(Mar 1971).

A field-ion microscope has been used to examine the evaporation rate of tungsten in strong fields at partial nitrogen pressures of $10^{-6} - 10^{-2}$ torr. The stimulated evaporation was recorded from the rate of increase in radius at constant voltage. The lower evaporation threshold coincides with the field corresponding to field ionization of nitrogen (150 mV/cm), and the rate of stimulated evaporation increases by four to five orders of magnitude as the nitrogen pressure varies in the range 10^{-5} to 5×10^{-5} torr. A recombination mechanism is proposed for the stimulated evaporation. (auth)

58228 ADSORPTION AND DESORPTION OF YTTERBIUM ON CARBONIZED TUNGSTEN. Marinova, Ts. S.; Zubenko, Yu. V. (Leningrad State Univ.). Sov. Phys.-Solid State (Engl. Transl.); 13: No. 3, 635-6(Sep 1971).

Translated from Fiz. Tverd. Tela; 13: No. 3, 769-71(Mar 1971).

The effect of the adsorption of ytterbium on the work function and desorption of the metal on carbonized tungsten in the presence of an electrical field has been studied in the field-emission microscope. It is shown that carbonizing the tungsten has no effect on the electron-emission properties of the system Yb–W. The heat of desorption of ytterbium ions has been determined as $l_{0+} = (3.1 \pm 0.1)$ eV for $\theta = 1$. (auth)

58229 INITIAL PHASES IN THE CONDENSATION OF ZIRCONIUM ON TUNGSTEN AND THEIR CONNECTION WITH SURFACE MIGRATION. Golubev, O. L.; Odishariya, G. A.; Shrednik, V. N. (Ioffe Inst. of Physics and Tech., Leningrad). Sov. Phys.-Solid State (Engl. Transl.); 13: No. 3, 628-34(Sep 1971).

Translated from Fiz. Tverd. Tela; 13: No. 3, 761-8(Mar 1971).

The condensation of Zr on single-crystal W has been studied by means of the field emission microscope. The amount of Zr deposited did not exceed 0.2 of a monatomic layer. At tungsten temperatures T from 80 to 180°K, the Zr formed a relatively uniform deposit. At W temperatures from 210 to 300°K, isolated accumulations of Zr built up on the {112}, {123}, and {110} faces and in the vicinity of these faces. Intermediate structures were found at T = 180–210°K. Heating the condensate obtained at 80 to 300°K resulted in structures typical of condensation at 300°K. The accumulations referred to above were stable up to 410°K, but in the range 410 to 515°K they disappeared irreversibly, light edges being formed on the emission patterns in the vicinity of the faces mentioned. At $T \geq 515°K$ these edges also broke down irreversibly. A check test on "thicker" deposits at 300°K revealed the existence of accumulations of Zr on the $\{112\}$ and $\{123\}$ faces of W up to coverings of about 0.7–0.8 of a monatomic layer without any subsequent preferential growth of three-dimensional crystals in these regions. The accumulations of Zr on the $\{112\}$, $\{123\}$, and $\{110\}$ faces of W are interpreted as small two-dimensional islands which are formed at $T > 210°K$ as a result of the residual relaxation path of the adatoms. Ordinary thermal migration makes an ever-increasing contribution to their formation at higher temperatures. The disappearance of the accumulations and the further changes at 410–515°K and higher may be regarded as the result of the operation of two processes, viz., the irreversible transition from the initial nonequilibrium distribution of the adsorbate over the faces to an equilibrium distribution (which is still far from complete at ~515°K) and the reversible phase transformations: two-dimensional gas $\rightleftharpoons$ crystal. (auth)

58230 DESORPTION OF YTTERBIUM AND NEODYMIUM FROM TUNGSTEN BY AN ELECTRIC FIELD. **Ionov, N. I.; Marinova, Ts. S. (Leningrad State Univ.). Sov. Phys.-Solid State (Engl. Transl.); 13: No. 3, 557-63(Sep 1971).**

Translated from Fiz. Tverd. Tela; 13: No. 3, 674-81(Mar 1971).

Electron field emission was employed to determine the relationship between the temperature T of a tungsten filament, the degree of coverage θ of the (111) and (001) faces of the filament with ytterbium and neodymium atoms, and the electric field E_g required for the desorption of the latter from the filament. In every case the value of E_g increased and the work function $\varphi(\theta)$ diminished as θ increased from 0 to 1. In the case of Nd the minimum work function φ of the faces corresponded to the maximum value of E_g for $\theta = 1$. In the case of Yb no such extermal values of φ and E_g were observed. For $\theta \leq 1$ the $E_g(\theta)$ curves exhibited steps apparently due to rearrangements in the structure of the adsorbate. From the experimental $\sqrt{E_g} = f(T)$ relationships, the heats of desorption l_{0+} of the Yb^+ and Nd^+ ions were determined, together with the relative lifetimes τ_0/τ of the adsorbed atoms with respect to desorption in the form of ions for $\theta = 0.3$ and 1. The resultant values of l_{0+} depended weakly on the θ of the faces; for $\theta = 1$ the values were 3.2, 3.3, and 3.7 eV (Yb) and 3.7, 3.95, and 4.4 eV (Nd) for the (121), (111), and (001) face, respectively. The relative error in determining these quantities was estimated at 10%. The field factor β for all faces of the tungsten filament fell smoothly by 5–6% on passing from the boundaries of the faces to the center. (auth)

58231 EFFECT OF THE DEFORMATION TEMPERATURE ON THE STRUCTURE AND MECHANICAL PROPERTIES OF LOW-ALLOYED MOLYBDENUM. **Vitorskii, Ya. M.; Ivashchenko, R. K.; Kaverina, S. N.; (and others) (Inst. of Metal Physics, Kiev). Fiz. Metal. Metalloved.; 31: No. 5, 1076-84 (May 1971). (In Russian).**

A low solubility of the majority of refractory metals in Mo seriously limits the possibility of modifying its properties. The role of structural characteristics and deformation in the formulation of the mechanical properties of Mo were investigated at various temperatures of deformation. Deformation at temperatures below 900°C resulted in anisotropy of the temperature of cold brittleness, and, as a consequence, ductility. Anisotropy of the temperature of cold brittleness is associated with a varied tendency of samples, cut out lengthwise and crosswise to the direction of rolling, toward stratification. (tr-auth)

58232 STUDY OF THE AGING OF TERNARY Fe–Ni–Mo AND QUATERNARY Fe–Ni–Co–Mo ALLOYS BY DILATOMETRY, ELECTRIC RESISTIVITY AND ELECTRON MICROSCOPY. **Servant, C.; Maeder, G.; Cizeron, G.; Lacombe, P. (Centre d'Etudes Nucleaires de Saclay, Gif-sur-Yvette, France. Paris Univ.). Mem. Sci. Rev. Met.; 68: No. 4, 201-13(Apr 1971). (In French).**

The study of ternary 74.15%Fe–20.49%Ni–5.36%Mo and quaternary 67.49%Fe–18.65%Ni–8.99%Co–4.87%Mo (wt) alloys demonstrated that the kinetics of precipitation and austenite formation are correctly described by Johnson–Mehl type equations. Phenomena associated with the transition towards 450 to 480°C are currently under investigation. The electron diffraction diagrams obtained from the thin films considered allowed only a rough determination of the precipitates formed during aging to be made. Accurate determinations of the resistivities corresponding to the precipitation and austenite formation were made using Johnson–Mehl equations. (France)

58233 EFFECT OF HEATING BY GLOW DISCHARGE ON THE PHYSICO-CHEMICAL SURFACE CONDITION OF SOLID ALLOYS. **Samsonov, G. V.; Mukha, I. M.; Dovbishchuk, M. N.; Kal'nenko, B. I. Elektron. Obrab. Mater.; No. 5, 32-8(1970). (In Russian).**

The effect of ionic heating on the physicomechanical surface properties of solid alloys of the Type VK, VK2, VK6, VK8, VK15, and VK20 and TK, T5K10, T15K6, and T30K4 and tungsten and titanium carbides during diffusion welding in a glow discharge is demonstrated. An analysis is presented of the variation of the chemical composition of surface layers as a function of the energy condition and the electron structure of the heated materials. (JPRS)

58234 NEW TIN–TITANIUM ALLOY. **Guernsey, J. B.; Petersen, V. C.; Dulis, E. J. Tin Uses; No. 84, 10-11(1970).**

A Ti alloy containing 11.5% Mo–6%Zr–4.5%Sn and called Beta III is reported to have good ductility at room temperature. Properties are listed in comparison with other Ti alloys. (Metals Abstr.)

58235 EFFECTS OF COMPOSITION OF HARDFACING ALLOYS ON THEIR HARDNESS. **Khutoryanskii, E. D.; Demyantsevich, V. P. Svar. Proizv.; No. 9, 9-11(Sep 1970). (In Russian).**

Studies on the ternary systems Fe–Co–Mo and Fe–Co–W were carried out to determine the effects of the primary addition elements (Co, Mo, and W) and secondary additions (Mn, Ni, Cr, and Ti) on the hardness of dispersion-hardening alloys used for hardfacing. Regression analysis established that, following remelting, the hardness of the alloys decreased with increasing Ni, Mn, and Co, while increasing W, Cr, and especially, Ti have the opposite effect. Alloys, with HRC <35 after remelting were characterized by the highest Co contents (36.5%) and highest tempering temperature (700°C). (Metals Abstr.)

58236 MICROHARDNESS AND INTERNAL STRESSES OF ELECTROLYTIC NICKEL–TUNGSTEN ALLOYS. **Vas'ko, A. T.; Shaturskaya, V. P. Elektron. Obrab. Mater.; No. 4, 54-7(1970). (In Russian).**

The microhardness of a number of electrolytically-deposited Ni–W alloys was studied and correlated with the internal stresses as determined by x-ray diffraction. Heat treatment (or increasing the c.d. employed in the electrodeposition) increased the microhardness of the alloys. All factors increasing the proportion of W in the alloy (e.g., a corresponding change in the chemical composition of the original solutions) reduced the internal stresses owing to an analogous change in the energy state of the constituent atoms. The internal stresses were sensitive to the presence of H. (Metals Abstr.)

58237 VARIATION IN THE SOLUBILITY OF CERIUM, PRASEODYMIUM, AND NEODYMIUM IN CHROMIUM WITH TEMPERATURE. **Kobzenko, G. F.; Kholodov, A. G.; Ivanchenko, V. G.; Martynchuk, E. L.; Kashevskaya, O. N. Dopov. Akad. Nauk Ukr. RSR, Ser. A; No. 11, 1045-8(Nov 1970). (In Ukrainian).**

The solubility of Ce, Pr, and Nd in Cr was studied at 1000 to 1800°C by metallographic analysis, x-ray diffraction, and microhardness measurements. The limiting solubilities were 1.2, 0.9, and 1.1 at. %, respectively. The rare earth metals had an appreciable effect on the hardness of original material. On alloying Cr containing O with rare earth metals, two distinct deoxidation processes (primary and secondary) took place. The degree of Cr deoxidation was greater for the primary process. (Metals Abstr.)

58238 VISCOSITY, DENSITY, AND AUTODIFFUSION IN MOLTEN, EQUIATOMIC INDIUM–BISMUTH ALLOY. **Petrescu, N. Rev. Met. (Madrid); 6: No. 5, 501-8(Sep-Oct 1970). (In Spanish).**

The viscosity, density, and diffusivity of a high-purity 50:50 In–Bi alloy were studied over the range 110 to 220°C, under vacuum, using oscillating-crystal, dilatometric, and capillary deposit techniques with ^{114}In and ^{210}Bi as radioactive tracers. Viscosity/temperature and diffusivity/temperature relations show significant departures from linear near the solidification temperature. This is attributed to the formation of short-range-order complexes. The dissociation coefficient binding constant, and volume fraction of bonds were calculated. (Metals Abstr.)

58239 EFFECT OF ZIRCONIUM ADDITIONS ON THE CREEP STRENGTH OF ALUMINUM–COPPER ALLOYS. **Screm, G.; Palumbo, D. Alluminio; 39: No. 11, 583-9(1970). (In Italian).**

Two Al alloys containing Cu 6.01 and Ti 0.11% and Cu 6.10, Ti 0.10, and Zr 0.35%, were compared in a series of creep and stress-rupture tests at 150 to 250°C. These tests indicate that Zr has more effect on the 1000 hr stress rupture values than on

XUM

elongation at rupture. Aging tests and electron-microscope studies supported the hypothesis that a grain-boundary blocking mechanism, caused by a Zr-rich grain-boundary precipitate, is responsible. (Metals Abstr.)

58240 ANISOTROPY OF SELF-DIFFUSION OF YTTRIUM. Gornyi, D. S.; Al'tovskii, R. M. Fiz. Metal. Metalloved.; 30: No. 1, 85-9(Jul 1970). (In Russian).

The self-diffusion coefficient of Y was studied in two mutually perpendicular crystallographic directions (along and across the c axis) at 900 to 1300°C. There was only a slight anisotropy of the diffusion characteristics, and this diminished with increasing temperature. The equations governing the diffusion coefficient were $D = 8.2 \times 10^{-1} \exp[-60{,}300/RT]$ and $5.2 \exp[-67{,}100/RT]$ cm^2/sec in the directions along and across the c axis, respectively. The anisotropy agreed with the value determined from independent data. (Metals Abstr.)

58241 TEMPERATURE RELAXATION IN METALS. Piterimov, V. A.; Mal'tseva, G. K. (Mordovia State Univ., Saransk, USSR). Fiz. Metal. Metalloved.; 30: No. 1, 175-80(Jul 1970). (In Russian).

Factors affecting the relaxation of vacancy concentration, interatomic distance, etc. in metallic crystals under the influence of a temperature field are discussed theoretically, with special reference to the frequency dependence of the temperature coefficient of electrical resistance in samples subjected to periodic changes of temperature. On the basis of this theory, a method of measuring the temperature coefficient of electrical resistance on the dynamic principle is proposed. An example of the use of this method in the case of W wires at 1400 to 2100°C is presented. For this material there is an anomalous change in the temperature coefficient of electrical resistance at 1700°C. (Metals Abstr.)

58242 COMPARISON OF STAINLESS STEEL AND ZIRCALOY-2 AS ENCAPSULATION MATERIALS FOR ^{252}Cf. Philbin, P. (Geological Survey, Washington, D. C.); Senftle, F.; Duffey, D.; Wiggins, P.; Evans, A. G. Nucl. Technol.; 12: No. 4, 404-6 (Dec 1971).

A comparison is made of the experimental neutron capture background from 3 MeV to 10 MeV of two ^{252}Cf neutron sources, one encapsulated in stainless steel and one in Zircaloy-2. The background of the Zircaloy-2 source was significantly lower than for the stainless steel source above 6 MeV because of the absence of the high energy capture gamma peaks due to iron, chromium and nickel. Below 5 MeV, the californium fission gamma-rays are the major source of interference. (auth)

58243 DATA ON ZIRCALOY CLADDING TUBES. Kobe Seiko Giho; 20: No. 2, 57-65(Apr 1970). (In Japanese).

Zircaloy-2 and -4 are used in nuclear reactors fueled by low-enrichment uranium dioxide and cooled and moderated with light water. Various properties of the alloys affect the design of a reactor and its fuel. Data collected on the properties of zirconium, Zircaloy-2 and -4, are presented in the form of figures and charts. Data are included on physical properties of zirconium, isotope ratio, thermal neutron absorption, and crystal structure. Data are also included on physical properties of Zircaloy-2 and -4, including density, thermal neutron absorption, thermal expansion, heat conductivity, Young's modulus, and Zr gas phases. Data on mechanical properties of Zircaloy-2 and -4, such as tensile property, creep characteristics and fatigue are presented. Corrosion properties of Zircaloy-2 and -4, including water corrosion, hydrogen absorption, solid solubility limit of hydrogen, and the relation of corrosion and oxide films are summarized. Irradiation effects, including the effects on mechanical properties and corrosion, are described. (Japan)

58244 SURFACE REACTIVITY AND BASIC ETCHING MECHANISM STUDIES ON GERMANIUM, ALUMINUM, AND URANIUM DIOXIDE. Ehamn, Michael Frederick. Philadelphia; Pennsylvania State Univ. (1970). 287p. University Microfilms Order No. 71-16,595.
Thesis.

A literature survey of the etchants and polishes for solid-state materials is presented which covers the literature from 1874 to 1970. Ellipsometric techniques were used to investigate the thin films that formed on cleaved germanium samples in air, deionized water, and 30% hydrogen peroxide. In all three cases the films were less than 100 Å in thickness. The films formed in air and water had a refractive index of 1.63 which is close to that of GeO_2. An increase of refractive index to about 1.74 was observed when the samples were immersed in a solution of 30% H_2O_2. The thickness of this film (~30Å) remained relatively constant in a period of 5 minutes to 6 hours. The film is attributed to a layer of $Ge(OH)_2^{2+}$ surface complexes, and a thick reaction envelope of metagermanic acid (H_2GeO_3). After rinsing surfaces covered with glassy GeO_2 with a 48% HF solution, the original oxide was removed; however, within 5 minutes a 30Å thick film of glassy GeO_2 had formed. Electron microprobe studies did not detect the presence of germanium monoxide. Studies on the effect of the concentration of the complexing agent in etching solutions showed that the etch rate is a function of the concentration when the concentration of the oxidizing agent is held constant. The {100} surfaces of germanium were etched in a solution of the basic composition $CPX : H_2O_2 : H_2O$ in the volume ratio 1 : 1 : 4 where CPX = tartaric, acetic, citric, oxalic, HCl, and HF acids, and mannitol. The variation in etch rates and activation energies with the complexing agent concentration indicated that the reactions are diffusion-controlled. A model is proposed for the crystal–solution interface which is consistent with the interdependence of the etch rates and the complexing ratio of the Ge. A comparison is made between optical and scanning electron microscopy techniques on germanium surfaces that have been etched in several common chemical etchants. The morphology of the etch pits due to dislocations and different types of surface preparation are discussed. The high resolution and depth of field of the scanning electron microscope allowed resolution of the fine structure of the etch figures. Single crystals of aluminum were etched under cavitation conditions in a 10% solution of sodium hydroxide. The cavitation processes prevented the buildup of oxide thin films, which under standard etching conditions would stop the etching processes. The etch rate of the aluminum at 60° was 0.460 $mg/cm^2/min$. The experimental activation energy determinations indicate that the rate-controlling step is diffusion with a value of $\Delta E_{act} = 3.9$ kcal/mole. A chemical etchant for UO_2 consisting of three parts concentrated HCl and one part concentrated HNO_3 was developed. This etchant, when used for ten minutes at 60°C on cleaved {111} surfaces, produced distinctive pits at dislocations intersecting the surfaces and at low-angle grain boundaries. The fact that the etch pits mark the sites of dislocations was shown by comparing the enlargement of pits with etching time and etch pits on matching cleavage faces. Comparison of etch rates at various temperatures gave an activation energy of 15.1 kcal/mole. (Diss. Abstr. Int., B)

58245 INFLUENCE OF THE NATURE OF A GRAPHITE LATTICE ON THE RATE OF IMPREGNATION BY MOLTEN ZIRCONIUM. Elyutin, V. P.; Kostikov, V. I.; Dergunova, V. S.; (and others). Tsvetn. Metal.; No. 4, 51-2(Apr 1971). (In Russian).

A porous graphite billet was machined into 20 × 60 mm cylinders which were heated, and then graphited with coke at 2000 to 2800°C. The samples thus prepared were submersed in liquid Zr at 1860, 2100, and 2250°C (5 to 20 sec). The data showed that at all temperatures the dependence of the impregnation rate on the interplanar distance in graphite was the same. The higher soaking temperatures lead to a decrease in the rate of impregnation. This temperature effect was explained by the formation of a Zr carbide on pore surfaces of the graphite. (K.S.W.)

58246 ADSORPTION AND DESORPTION OF RESIDUAL GASES ON A TUNGSTEN SURFACE IN A STRONG ELECTRIC FIELD. Suvorov, A. L.; Kukavadze, G. M. (Inst. of Theoretical and Experimental Physics, Moscow). Fiz. Metal. Metalloved.; 30: No. 1, 116-25(Jul 1970). (In Russian).

The adsorption of residual gas atoms and molecules on a W surface cleaned by evaporation in a strong electric field was studied using a field-ion microscope. Different crystallographic planes exhibited appreciably differing adsorption capacities, particularly in the early stages of the process. The manner in which the adsorbed atoms and molecules tended to arrange themselves on the W surface was clearly represented in the ion images obtained. On applying a strong electric field some of the adsorbed molecules underwent desorption, while others migrated over the surface. (Metals Abstr.).

58247 EFFECTS OF THERMAL CYCLING OF MONOCRYSTALS OF TUNGSTEN–MOLYBDENUM ALLOYS. Savitskii, E. M.; Burkhanov, G. S.; Tetyueva, T. V.; Kuz'mishchev, V. A. (Inst. of Metallurgy, Moscow). Dokl. Akad. Nauk SSSR; 198: No. 2, 373-6(11 May 1971). (In Russian).

Thermal cycling of monocrystals of Mo–40% Nb in a helium atmosphere 20 times across the interval 1,600 to 400°C caused a decrease in unit dimensions in the monocrystal by a factor of ten, and an increase in the angular disorientation of the unit from 60 to 180′. The addition of as little as 5% of Re to either W or Mo increases their structural stability towards thermal cycling. Re is believed to lower the energy of formation of packing defects of W and Mo, and to increase their tendency to twin. (K.S.W.)

58248 MECHANICAL PROPERTIES OF MOLYBDENUM-BASE ALLOYS. Zhukova, E. G.; Kolikova, G. P.; Voronin, Yu.

XUM

V. Sb. Tr. Tsent. Nauch.-Issled. Inst. Chern. Met.; No. 72, 141-6(1970). (In Russian).

The effects of various W and Zr contents on the recrystallization temperature and mechanical properties of Mo were studied. Study was made of binary alloys of Mo–W containing W 2, 4, 6, 10, and 15%, and also ternary Mo–W–Zr (Zr 0.15% + W 2, 4, 6, 8, or 15%) sintered alloys. The alloys have good plastic deformation properties because they possess small grain sizes after sintering and high hardness (20 to 30 μm and HB ~ 150 kg/mm^2). Ternary alloys containing W 6-15% and Zr 0.15% had the highest recrystallization temperature, i.e. 1250°C Mo–W–Zr alloys, in the cold worked condition, had an UTS of 110 kg/mm^2 which is greater than that for the Zr-free alloys (75 kg/mm^2). Annealing at 1200°C causes a marked softening of all the alloys that is evidently associated with the recrystallization processes. (Metals Abstr.)

58249 NITROGEN SOLUBILITY IN METALS OF HIGH MELTING POINTS. **Jehn, H.; Hoerz, G.; Fromm, E. (Max-Planck-Institut fuer Metallforschung, Stuttgart). Metall; 25: No. 7, 783-9(Jul 1971). (In German).**

Nitrogen solubility in high-melting metals such as vanadium, niobium, tantalum, chromium, molybdenum, and tungsten was examined. The results of studies of the nitrogen system in the VIa- and VIIα-metals within the ternary combinations (Nb–Mo–N, and Mo–W–N) are emphasized. Between the vanadium and the VIa group, a fundamental difference with respect to the nitrogen system is displayed, i.e., a continuous transition manifests itself between ternary and binary combinations. The reaction kinetics that establish equilibrium are briefly described. Also compiled are isobar nitrogen solubility, saturation concentration, and diffusion coefficients for binary nitrogen systems of metals with high melting points. (H.B.G.)

58250 ALLOYING OF MAGNICO ALLOY WITH NEODYMIUM. **Larina, L. S.; Chernov, V. M. Liteinoe Proizvod.; No. 1, 31-2 (Jan 1970). (In Russian).**

Magnico permanent-magnet alloys of the composition Co 23, Ni 13.5, Al 8.5, Cu 3, S 0.2, Ti 0.3%, remainder Fe, were prepared in high frequency induction furnace with additions of Nd 0.001, 0.002, 0.005, 0.05, 0.1, and 0.5%. The alloys were characterized by a dendritic structure, polishing capacity, and high magnetic properties. (Metals Abstr.)

58251 OXIDATION BEHAVIOUR OF NICKEL–VANADIUM ALLOYS IN AIR. **Kramer, K. H.; Borgstedt, H. U. Werkst. Korros.; 21: No. 10, 804-9(Oct 1970). (In German).**

When pure Ni is oxidized in air at 1000°C a simple NiO film is formed. When Ni–V alloys are oxidized, an outermost layer consisting mainly of Ni with a small $Ni(VO_3)_2$ content is produced. Below this is a second oxide layer with a high V content on the outside, and a low content of both metals on the inside. The innermost oxidation layer penetrates into the matrix as conic islands with concentrations of V_2O_3. The oxidation reactions obey parabolic laws for the formation of the outer NiO layers with Ni, and of NiO and $Ni(VO_3)_2$ with the Ni–V alloys. The activation energy of the oxidation is ~50 kcal/mole. (Metals Abstr.)

58252 HIGH-STRAIN-RATE DEFORMATION OF CADMIUM SINGLE CRYSTALS. **Schweighofer, Augustin; Polakovic, Anton. Kovove Mater.; 8: No. 4, 389-401(1970). (In Slovak).**

Dynamic behavior in compression at room temperature of Cd single crystals (99.999% purity) was investigated using a bar-type impulse test with a strain rate of 10^2/sec. Critical resolved shear stress measured at this rate was 9 times higher than that obtained at quasi-static test (strain rate ~10^{-3}/sec), but the hardening exponent remained practically unchanged. The deformation of Cd single crystals at the high strain rate (10^2/sec) was controlled by basal slip. (Metals Abstr.)

58253 HARDNESS OF ALLOYS IN THE MAGNESIUM–CADMIUM AND TELLURIUM–BISMUTH SYSTEMS. **Shishokin, V. P.; Bazilevskii, L. N. Tr. Leningrad. Politekh. Inst.; No. 305, 88-91(1970). (In Russian).**

Peculiarities in the hardness of some Mg–Cd and Te–Bi alloys are considered. In some of these alloys there is no linear dependence of the log indentation diameter (or log hardness number) on temperature. This is shown to be associated with the occurrence of supplementary physicochemical processes in these alloys. (Referativnyi Zh.)

58254 DOES THE OXIDATION OF ZIRCONIUM OBEY WAGNER'S THEORY? Lacombe, P.; Beranger, G.; Boisot, P.; Com-Nougue, J. Werkst. Korros.; 21: No. 12, 1010-15(Dec 1970).

The O diffusion in Zr follows a parabolic law from its initiation. Wagner's theory of diffusion in a homogeneous phase with the formation of an oxide layer has previously been found to be in good agreement with kinetics results for the steady state. However, the model cannot be directly applied to O diffusion in Zr and zirconia, and should be adapted to take into account the different atomic scale phenomena, especially the O diffusion in Zr. There is an initially disturbed oxidation period which implies a transitory state for the oxide growth. (Metals Abstr.)

58255 POWDER METALLURGICAL PRODUCTION OF NEUTRON-ABSORBER UNITS FOR NUCLEAR REACTORS FROM CHROMIUM–NICKEL STEEL WITH BORON CARBIDE BINDER AND ALSO FROM FERRO-BORON. **Spyra, Wolfgang; Gruenewald, Herbert. Dew Tech. Ber.; 10: No. 3, 270-3(Oct 1970). (In German).**

Porosity, B content, and pressure strength were determined for different sintering conditions and preliminary pressing conditions. Cr–Ni steels containing B 12.6 and 18% and ferro-B were sintered in the range 800 to 1100°C under high-purity H and under vacuum. Under specified manufacturing conditions it was possible to produce work-pieces fully complying with the desired value ranges for shape, porosity, B content, and compressive strength. (Metals Abstr.)

58256 STUDY OF THE ELECTROCHEMISTRY AND MORPHOLOGY OF ELECTRO-DEPOSITED NICKEL–MOLYBDENUM ALLOYS. **Hooper, R. A. E.; Gabe, D. R.; West, J. M. Trans. Inst. Metal Finish.; 48: No. 5, 182-90(1970).**

The most suitable solution for deposition of Ni–Mo alloys is one containing Na citrate, Ni sulfate, and Na molybdate buffered to pH 10.5 with ammonium hydroxide. The deposits consist of a fcc solid solution of Ni–17 at. % Mo. Structures and hardnesses of the deposits are reported and discussed in relation to their formation conditions. (Metals Abstr.)

58257 EFFECT OF CARBON AND ADDITION OF ELEMENTS BELONGING TO THE IRON GROUP ON MECHANICAL PROPERTIES OF MOLYBDENUM AND TUNGSTEN SINGLE CRYSTALS. **Kopecky, V.; Paschkowsky, A. I. Planseeber. Pulvermet.; 19: No. 1, 7-17(Mar 1971). (In German).**

The tensile strength, elastic limit, elongation, and reduction of area of zone-melted tungsten and molybdenum single crystals as a function of crystal orientation and test temperature were determined. The effect of carbon additions and, in the case of molybdenum, of iron-group metals, on these mechanical properties of the single crystals was also investigated. Large differences between the single crystals with ⟨100⟩- and ⟨110⟩-orientation were found, particularly with regard to the ductility. The hardening effect of carbon is probably due to the formation of substructures and grain refinement and a blocking of dislocations through carbide precipitates. In molybdenum with iron-group metal alloying additions, the interaction between the dislocations and interstitial alloying additions is weakened which generally improves the ductility, especially in the ⟨100⟩-crystals. (auth)

58258 MODIFICATION OF CAST ZIRCONIUM BY ADDITIONS OF TRANSITION METALS. **Samsonov, G. V.; Kashuk, V. A.; Filippov, B. F. (Kiev Polytechnic Inst.). Izv. Vyssh. Ucheb. Zaved., Tsvet. Met.; No. 2, 104-8(1971). (In Russian).**

The influence of small additions of the fourth period elements of the periodic system on the properties of cast Zr was investigated. Ten alloys of Zr were prepared from each of the following: Ti, V, Cr, Mn, Fe, Co, and Ni. Grain size, microhardness, and electric conductivity were measured and compared. The strongest modifying influence was revealed to be the metals of Group VIII. (K.S.W.)

58259 EFFECT OF NITRIDING ON THE PROPERTIES OF TANTALUM. **Kiparisov, S. S.; Levinskii, Yu. V.; Strogonov, Yu. D. (Moscow Inst. of Steel and Alloys). Izv. Vyssh. Ucheb. Zaved., Tsvet. Met.; No. 2, 109-11(1971). (In Russian).**

The effects of temperature and time of nitriding of Ta on its tensile strength, relative elongation, and surface hardness were investigated. A temperature range of 1,000 to 1,400°C and nitriding times from 15 min to 6 hr were tested. The data showed that most satisfactory nitriding is accomplished at 1,100°C in one hour. (K.S.W.)

58260 ZONE LIQUATION IN NIOBIUM ALLOY INGOTS OBTAINED BY ELECTRONIC MELTING. **Suvorov, A. M. Izv. Vyssh. Ucheb. Zaved., Tsvet. Met.; No. 2, 112-17(1971). (In Russian).**

The chemical composition of finished ingots and condensate was determined for Nb–W and Nb–Mo alloys which had different re-melting treatments. Fusion by a fixed electronic gun rotating at 3,000 rpm resulted in greater nonhomogeneity of alloy composition than in melting with rotational speeds of 30 rpm. The progress of reverse liquation in ingots is explained by the char-

XUM

acter of solidification of the alloy, determined by its position in the phase diagram and by the thermal history of the ingot. (K.S.W.)

58261 PREFERRED POSITION OF TUNGSTEN CARBIDE IN THE COMPOSITION OF HARD METALS. Koelbl, F. (Metallwerk Plansee, Reutte, Austria). Planseeber. Pulvermet.; 19: No. 1, 18-24(Mar 1971). (In German).

In the production of hard metals, the carbides of tungsten, titanium, and tantalum are important as to hardness, whereby the tungsten monocarbide claims a preferred position. At least 98% of all hard metals contain WC as basic carbide, and perhaps 50% represent pure tungsten carbide—cobalt hard metals. Reasons for the preferred position of tungsten carbide are discussed with respect to physics, powder metallurgy, and sintering. An outstanding quality of tungsten carbide is its producibility in very wide ranges of grain size. In addition to pure tungsten carbide, the effect of other carbides on properties of hard metals is discussed. (H.B.G.)

58262 INFLUENCE OF ADDITIVES ON THE FORMATION OF PERIODIC PRECIPITATION (LIESEGANG BANDS) IN THE Ag–Cd SYSTEM. Shen, Y. S.; Zdanuk, E. J.; Krock, R. H. (P. R. Mallory and Co. Inc., Burlington, Mass.). Met. Trans.; 2: No. 10, 2839-44(Oct 1971).

Extensive regions of Liesegang bands, or periodic precipitation, are observed in composite materials prepared by the internal oxidation of Ag–9 Cd alloys containing small amounts of certain metallic elements: Al, Be, Mg, Sc, and Y. The elements which induce this form of distribution of oxide particles possess the following characteristics: relatively small atomic radius (less than 1.80 Å), high oxidation potential (higher than 1.66 V), and some solid solubility in silver at 800°C. In this solid-state system the constancy of the spacing coefficient, the ratio of distances from the surface of consecutive bands, is generally satisfied. The spacing coefficient is found to be dependent on a) the specific additive, b) the concentration of the additive, c) the concentration of the oxygen, and in some cases d) the crystal orientation. (auth)

58263 APPLICATION OF THE X-RAY SYNERGY METHOD TO ANALYSIS OF ROOM TEMPERATURE COMPRESSION OF BERYLLIUM CRYSTALS. Glass, H. L. (Autonetics, Anaheim, Calif.); Weissmann, S. Met. Trans.; 2: No. 10, 2865-74(Oct 1971).

A recently developed method (synergy method) was applied to zone-refined beryllium crystals compressed at room temperature. The synergy method, combining x-ray diffraction line profile analysis, x-ray topography, and metallography, is capable of analyzing lattice defects in small volume elements of the crystal (10-μ dia cross section by 5 mm in this case). Crystals oriented for basal slip, prism slip, and c-axis compression were examined. The existence of a columnar growth substructure was shown, which determined the response of the crystal to subsequent deformation. Inhomogeneous lattice rotation and basal plane bending induced by the interaction of basal slip dislocations with the columnar subgrain boundaries appeared to be a precursor of bend plane splitting. Crystals oriented for prism slip exhibited extensive twinning and those for c-axis compression gave rise to extensive basal slip. The predominance of basal slip in beryllium during room temperature deformation was found to be consistent with unique, anisotropic bonding characteristics. (auth)

58264 EFFECT OF DEFORMATION ON ThO_2 PARTICLE MORPHOLOGY IN W–1 WT. PERCENT ThO_2 MATERIALS. Dunham, T. E. (General Electric Co., Cleveland). Met. Trans.; 2: No. 10, 2797-2804(Oct 1971).

The distribution and deformation characteristics of ThO_2 particles during processing from powder to wire were investigated in a W–1 wt % ThO_2 material. The results indicate that larger thoria particles (>1 μm) deform concomitantly with the matrix to cigar-shaped particles and then fracture into segments as deformation of the matrix continues. Smaller particles remain relatively spherical and are not deformed. The net effect of this process is to superpose a nonuniform distribution of large particle segments on a background of small, undeformed, uniformly distributed particles. The consequences of this change in thoria dispersion morphology in reference to work hardening, recrystallization, and fracture of tungsten–thoria materials are discussed. In addition, some conclusions are drawn as to the origin of the large, deformable thoria particles and the effect of different processing modes on the resultant dispersion morphology. (auth)

58265 THERMODYNAMICS OF TITANIUM ALLOYS. II. THE Ti–Mo SYSTEM. Hoch, M.; Viswanathan, R. (Univ. of Cincinnati). Met. Trans.; 2: No. 10, 2765-7(Oct 1971).

The activity of titanium in Ti–Mo alloys containing from 30 to 100 at. % Ti was measured using the triple Knudsen cell technique. The binary system shows positive deviation from ideality. The regular solution parameter, Ω, which is independent of temperature and composition, was determined to be 2.9 ± 0.7 kcal per mol. This value agrees quite well with values calculated from the phase diagram, and with those obtained from theoretical calculations. (auth)

58266 DIFFUSION OF SUBSTRATE ATOMS INTO A SURFACE FILM AS INDICATED BY THE SECONDARY ION–ION EMISSION CHARACTERISTICS. Abramenkov, A. D.; Fogel, Ya. M.; Slezov, V. V.; Tanatarov, L.V.; Ledenev, O. P. Fiz. Metal. Metalloved.; 30: No. 6, 1310-12(Dec 1970). (In Russian).

The diffusion of Mo atoms into Ti and Cr films continuously deposited on a Mo substrate was studied by a method based on secondary ion–ion emission. The diffusion coefficient for the Mo/Ti and Mo/Cr systems was $D = 5.3 \times 10^{-3} \exp[-64{,}000/kT]$ and $D = 1.6 \times 10^{-2} \exp[-67{,}000/kt]$, respectively. The results agreed closely with independent data for the Mo/Cr system but systematic discrepancies occurred for Mo/Ti. Possible reasons are discussed. (Metals Abstr.)

58267 THERMAL DIFFUSION OF TRACES OF THALLIUM IN VARIOUS MOLTEN METALS. Kuz'menko, P. P.; Golovinskii, L. P. Fiz. Metal. Metalloved.; 30: No. 6, 1304-7(Dec 1970). (In Russian).

The thermal diffusion of Tl in molten Zn, In, Sn, Pb, and Bi was studied by a stationary method, using a system of capillaries in order to eliminate interference from convection. In all the metals except Bi, phonon drag constituted the major factor determining the motion of the impurity (moving towards the cold end). In the case of Bi the effects of thermal pressure predominated and the impurity moved towards the hot end. The results support existing theory. (Metals Abstr.)

58268 EFFECTS OF Mn, Si, Cr, AND Ni ON THE REACTION OF SOLUTION AND PRECIPITATION OF NIOBIUM NITRIDE IN IRON AUSTENITE. Koyama, Shinji; Ishii, Teruo; Narita, Kiichi (Central Research Lab., Kobe, Japan). J. Jap. Inst. Metals; 35: No. 7, 698-705(Jul 1971). (In Japanese).

The effects of manganese, silicon, chromium, and nickel on the solubility of niobium nitride in iron austenite have been studied by the method in which iron austenite was equilibrated with nitrogen gas. Manganese and chromium contained in iron austenite increase the solubility of NbN while silicon decreases the solubility of NbN. Nickel, in lower content, increases the solubility of NbN, but in much higher content, decreases it. The effects of those elements are more marked with decrease of temperature. Such changes are attributed to the effect of each element on the activity of niobium as well as that of nitrogen. Solubility product of NbN in iron austenite containing manganese, silicon, chromium, or nickel is described by the following experimental equation, respectively: $\log[\%\,\mathrm{Nb}][\%\,\mathrm{N}] = -8500/T + 2.89 + (1085/T - 0.68)[\%\,\mathrm{Mn}] - (48/T + 0.032)[\%\,\mathrm{Mn}]^2$, $\log[\%\,\mathrm{Nb}][\%\,\mathrm{N}] = -8500/T + 2.89 + (1900/T - 1.103)[\%\,\mathrm{Si}]$, $\log[\%\,\mathrm{Nb}][\%\,\mathrm{N}] = -8500/T + 2.89 + (1290/T - 0.77)[\%\,\mathrm{Cr}] - (51/T + 0.034)[\%\,\mathrm{Cr}]^2$, $\log[\%\,\mathrm{Nb}][\%\,\mathrm{N}] = -8500/T + 2.89 + (694/T - 0.44)[\%\,\mathrm{Ni}] - (29/T + 0.0178)[\%\,\mathrm{Ni}]^2$. (auth)

58269 EFFECTS OF GRAIN SIZE AND CARBON CONTENT ON THE DUCTILITY OF RECRYSTALLIZED MOLYBDENUM WIRE. Aritomi, Noriyoshi; Tsuya, Kazuo (National Research Inst. for Metals, Tokyo). J. Jap. Inst. Metals; 35: No. 7, 662-70(Jul 1971). (In Japanese).

To clarify the effects of both grain size and carbon content on the ductility of molybdenum, the variations in ductility with grain size were investigated on the three grades of 1 mm ϕ wire specimens by means of tensile tests at 25 and −76°C, respectively. These specimens differed in carbon contents as <10 ppM, 80 ppM, and 210 ppM. Oxygen and nitrogen contents were essentially of the same order for all of the specimens. It was found that specimens containing ≤10 ppM carbon were extremely low in ductility due to intergranular brittleness when the average grain diameter in the transverse cross section was larger than about 0.04 mm, though they showed high ductility when it was smaller than 0.04 mm. In the fine grained specimens, however, the effect of grain size, per se, was obscured because the recrystallized grains were greatly elongated in the direction of the specimen axis and because of an abnormal increase in yield stress. At −76°C, the ductility of specimens containing 80 ppM carbon increased with increasing grain size when the average grain diameter was larger than about 0.08 mm. In specimens containing 210 ppM carbon the ductility increased nearly linearly with increasing inverse square root of the average grain diameter. In these specimens, however, the size of grain boundary carbides and the distribution of carbides in matrices also varied with grain size. When the average grain diameter in transverse cross section was larger than about 0.04 mm, both of the specimens containing 80 and 210 ppM carbon were clearly more ductile than the specimens containing ≃10 ppM carbon; which indicates that a suitable amount of carbon suppresses the intergranular brittleness and increases the ductility. Since coarse carbides act as fracture initiation sites, the specimens containing 80 ppM carbon which were free from the intergranular brittleness but did not contain coarse carbides, were most ductile. When the average grain diameter in transverse cross section was smaller than about 0.04 mm, the ductility of the specimens containing ≃10 ppM carbon was as high as or higher than that of the specimens containing 210 ppM carbon. However, considering the uniaxed recrystallized structures in the former, it was not clear whether carbon increases or lowers the ductility in an equiaxed fine grained molybdenum. (auth)

58270 LEED STUDY OF THE ADHESION OF COPPER AND TUNGSTEN TO THE (111) SURFACE OF NICKEL. Buckley, Donald H. ASLE (Amer. Soc. Lubric. Eng.) Trans.; 13: No. 1, 39-45(Jan 1970).

Adhesion studies were conducted with Cu, W, and oxidized W contacting a Ni(111) surface. The Cu, W, and oxidized W were 1-mm dia flat-ended fibers which contacted the Ni surface at loads of 30 to 150 mg and surface contact times of 10 to 300 sec. The Ni(111) surface was examined before and after adhesion contact with LEED. With clean metals in adhesive contact, fracture in tension occurred in the lower cohesive strength material. When Cu contacted Ni, a surface alloy formed. The adhesion of clean Ni to an oxidized W surface resulted in O transfer from W to Ni with atomic surface rearrangement of the O. (Metals Abstr.)

Structure and Phase Studies

58271 (CALT-767-P-3-19) OBSERVATION OF SLIP BANDS IN MOLYBDENUM SINGLE CRYSTALS BY X-RAY DIFFRACTION. Boyce, R. F.; Vreeland, T. Jr. (California Inst. of Tech., Pasadena. W. M. Keck Lab. of Engineering Materials). [1968]. 7p. Dep. NTIS.

Berg–Barrett x-ray topographs of slip bands in Mo $\{124\}$ surfaces were compared with the electrolytic etch pit pattern. The darkened area corresponds in size and shape to the etch pitted area, indicating that the Berg–Barrett technique reveals the true extent of the slip band. (D.L.C.)

58272 THEORY OF PHASE TRANSITIONS IN THE β-TUNGSTEN STRUCTURE INDUCED BY THE BAND JAHN–TELLER EFFECT. Pytte, E. (IBM Watson Research Center, Yorktown Heights, N. Y.). Phys. Rev., B; 4: No. 4, 1094-1100 (15 Aug 1971).

A dynamic theory of the cubic-to-tetragonal transformation in the β-tungsten structure is presented starting with a Hamiltonian describing the interaction between static strain and acoustic phonons with the electrons in the triply degenerate d bands. For this model the elastic constants are strongly temperature dependent in the low-frequency limit. However, for frequencies in the neighborhood of the Debye frequency, they are nearly temperature independent. (auth)

58273 STUDY OF THE MOLYBDENUM–ZIRCONIUM–CARBON SYSTEM. Zakharov, A. M.; Novikov, I. I.; Parshikov, V. G. Izv. Akad. Nauk SSSR, Metal.; No. 6, 204-7(Nov-Dec 1970). (In Russian).

The Mo–Zr–C phase diagram was studied by microstructural analysis, x-ray diffraction, thermal analysis, and measurements of microhardness, with special reference to the Mo corner; isothermal sections were plotted at 1200 to 2100°C. Between these temperatures Mo_2C, a ZrC-base solid solution, and Mo_2Zr were in equilibrium with the Mo solid solution. The Mo–ZrC section was of a quasi-binary nature with a eutectic melting point at 2260°C. The solubility of ZrC in Mo fell slowly with rising temperature. (Metals Abstr.)

58274 ALLOYS OF YTTRIUM WITH DYSPROSIUM AND HOLMIUM. Markova, I. A.; Terekhova, V. F.; Savitskii, E. M. Izv. Akad. Nauk SSSR, Metal.; No. 6, 170-5(Nov-Dec 1970). (In Russian).

The phase diagrams of the Y–Dy–Ho and Dy–Ho systems were studied by microstructural analysis, x-ray diffraction, thermal analysis, and measurements of hardness and electrical resistance. Both systems constituted continuous series of solid solutions. The solubility characteristics of the binary system were exactly reflected in the corresponding characteristics of the ternary system. The manner in which the physical properties of the ternary system varied with composition agreed closely with the Kurnakov laws relating to binary systems. The ductility of the alloys makes them suitable for wire-drawing. (Metals Abstr.)

58275 INFLUENCE OF CRYSTAL LATTICE DEFECTS ON THE HIGH-ENERGY PROTON SHADOW EFFECT [IN MOLYBDENUM]. Ivanov, L. I.; Makhlin, N. A. Izv. Akad. Nauk SSSR, Metal.; No. 6, 154-7(Nov-Dec 1970). (In Russian).

The effect of dislocations introduced into Mo single crystals by plastic deformation on the proton diffraction patterns of the corresponding material, and in particular on the proton "shadow" effect, was studied and correlated with the existing data relating to other metals (Al, Au, etc.). The shadow effect was very sensitive to the presence of dislocations and the structure of dislocation networks. Possible ways of exploiting this relationship are considered. (Metals Abstr.)

58276 STRUCTURE OF GALLIUM–INDIUM ALLOYS IN THE MOLTEN STATE. Romanova, A. V.; Mel'nik, B. A. Izv. Akad. Nauk SSSR, Metal.; No. 6, 158-64(Nov-Dec 1970). (In Russian).

The structure of Ga–In alloys in the molten state was studied by x-ray diffraction. Both eutectic and other alloys exhibited a "quasi-eutectic" structure in the molten state with large micro-inhomogeneities of density. This effect appeared very strongly near the melting point but was also noticeable at 300°C above the liquidus. Loose regions of pure In and Ga also appeared in the melts. Raising the temperature gradually eliminated the quasi-eutectic structure as mutual dissolution set in. (Metals Abstr.)

58277 STRUCTURAL PECULIARITIES OF POLYCRYSTALLINE MOLYBDENUM HARDENING DURING EXTRUSION. Mochalov, G. A.; Evstyukhin, A. I. (Moscow Engineering-Physics Inst.). Fiz. Metal. Metalloved.; 31: No. 5, 1085-7(May 1971). (In Russian).

The possible reasons for unusual changes in molybdenum structure during hydroextrusion were experimentally investigated. In contrast to the usual methods of ductile reworking, a single-pass hydro-extrusion of molybdenum with a considerable amount of reduction resulted in a vortex structure with hair-like dimensions in the transverse direction. In the longitudinal direction the grain was very much elongated, forming a fibrous structure. (K.S.W.)

58278 DIRECT OBSERVATION OF FLUCTUATIONS OF DEUTERIUM DISTRIBUTION IN $(Nb_{0.33}Ti_{0.66})D_{0.33}$. Miron, N. F.; Shcherbak, V. I.; Fykin, L. E.; (and others). JETP Lett. (USSR) (Engl. Transl.); 13: No. 12, 485-7(20 Jun 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 13: No. 12, 686-8(20 Jun 1971).

An x-ray-diffraction and neutron-diffraction study was made of $Nb_{0.33}Ti_{0.66}D_{0.33}$. The deuteride was found to retain the bcc arrangement of the initial alloy $Nb_{0.33}Ti_{0.66}$, indicating a solid solution of D in the alloy. The neutron diffraction patterns show, besides the bcc reflections, an intense diffuse maximum in the 2θ interval from 20 to 40°; this diffuse reflection is due to fluctuations of the distribution of the D atoms. (D.L.C.)

58279 STRUCTURE OF ANOMALOUSLY COARSE GRAINS IN SECONDARY RECRYSTALLIZATION OF TUNGSTEN FOILS. Zasimchuk, E. E.; Isaichev, V. I. (Inst. of Metal Physics, Kiev). Fiz. Metal. Metalloved.; 30: No. 1, 189-92(Jul 1970). (In Russian).

The secondary recrystallization of a thin (50 μm) W foil vacuum-annealed at 1000 to 2300°C and then electropolished in KOH solution with a current density of 10 A/cm^2 was studied by optical microscopy and by an x-ray method using a two-crystal spectrometer. Anomalously large grains developed at 1800 to 2300°C; the structure of these was less perfect than that of the primary recrystallization grains, in opposition to existing data (Dunn and Koch, Acta Met., 5: 548(1957)). The reasons for this discrepancy are discussed. (Metals Abstr.)

58280 STRUCTURE OF DECOMPOSED Co–Nb ALLOY. Kokorin, V. V.; Tkachenko, O. E.; Chuistov, K. V. (Inst. of Metal Physics, Kiev). Fiz. Metal. Metalloved.; 30: No. 1, 69-76(Jul 1970). (In Russian).

Structural changes taking place during the decomposition of the supersaturated solid solution in Co–4 wt % Nb alloys were studied by electron microscopy. Some structural inhomogeneities arising as a result of the decomposition of the high-temperature β-phase prevented the complete transformation of the latter into the α-phase. The stabilization of the β-phase was attributed to a dislocation mechanism involving a martensite-like phase transformation in Co. A simplified model of this mechanism is proposed. (Metals Abstr.)

58281 STRUCTURAL TRANSFORMATIONS IN COBALT–VANADIUM MELTS. Filippov, E. S.; Krestovnikov, A. N. Izv. Vyssh. Ucheb. Zaved., Chern. Met.; No. 9, 122-6(1970). (In Russian).

Structural transformations taking place in Co–V melts were studied by measuring the density, the geometric shape and size of the molten drops, and the relative light emission of various components. Plotted in the form of a conventional phase diagram, these results appeared to constitute the combination of a system of the eutectic type with a peritectic system. Some of the thermal effects observed were attributed to the vacancy mechanism governing the melting of the metals. (Metals Abstr.)

58282 RECRYSTALLIZATION AND CARBIDE PHASE FORMATION PROCESSES IN MOLYBDENUM BASE ALLOYS. Skakov, Yu. A.; Mezhennyi, Yu. O.; Zueva, I. B.; Spiridonov, V. B.; Selivanov, V. A. (Moscow Inst. of Steel and Alloys). Izv. Vyssh. Ucheb. Zaved., Chern. Met.; No. 3, 114-18(Mar 1971). (In Russian).

Using electron microscopy, microdiffraction, and x-ray methods, the structural features of two molybdenum alloys with various carbon contents were studied. In a low carbon alloy the state of the supersaturated solid solution is maintained after recrystallization annealing is carried to the point of embrittlement. Alloying with Re is not sufficient to cause embrittlement. The observed expansion of the grain boundaries in the brittle state is not connected with either localization of the carbide phase or with noticeable concentration enrichment of the boundary zones. (INIS)

58283 CONDITIONS FOR THE FORMATION OF OMEGA PHASE IN ALPHA + BETA TITANIUM ALLOYS. Dontsova, S. G. Tr. Irkutsk. Politekh. Inst.; No. 52, 34-44(1969). (In Russian).

The effects of alloying on ω phase formation in $\alpha + \beta$ Ti alloys was considered with particular reference to literature data on the effects of pressure. Using Ti–V alloys as an example, consideration was given to the influence of temperature on the difference in the specific volume of the α and β phases, and a formula was derived for calculating the probability of ω phase formation at various temperatures of the isothermal holding. The data on the temperature-dependence of the lattice constants of the β solid solution can be used to predict the heat-treatment conditions that will avoid embrittlement of Ti alloys by ω phase formation. (Referativnyi Zh.)

58284 INVESTIGATION OF FINE STRUCTURE PARAMETERS OF Al–W, Al–Mo, AND Al–Mn ALLOYS OBTAINED AT HIGH COOLING RATES. Burov, L. M.; Sheiko, T. I.; Bashev, V. F. (Dnepropetrovsk State Univ., USSR). Fiz. Metal. Metalloved.; 30: No. 1, 222-4(Jul 1970). (In Russian).

The structure of Al–W, Al–Mo, and Al–Mn alloys obtained by projecting drops of molten metal onto a rotating brass cylinder by means of a compressed air jet (achieving cooling rates of 10^7 °C/sec) was studied by x-ray diffraction. The sizes of the coherent-scattering region were determined in relation to the percentage of the second element in each case. For example, in pure Al a typical size was 1.3×10^{-5} cm, but on adding 2% of Mo or W this fell to 0.8×10^{-5} cm. The lattice constant changed analogously. (Metals Abstr.)

58285 RECRYSTALLIZATION OF COPPER REINFORCED WITH TUNGSTEN. Ozhigov, L. S.; Somov, A. I.; Chernyi, O. V. (Kharkov State Univ.). Fiz. Metal. Metalloved.; 30: No. 2, 447-8(Aug 1970). (In Russian).

The recrystallization of electron-beam-refined Cu reinforced with W wires 10 to 50 μm in dia was studied. The W occupied up to 25 vol.% of the whole samples. The W wires acted in the same way as dispersed particles of the same general size, in that they created local concentrations of lattice distortions which facilitated the formation of recrystallization centers and reduced the temperature corresponding to the onset of recrystallization by 80 to 100°C. (Metals Abstr.)

58286 CLASSIFICATION OF THE INDIUM–ZINC EUTECTIC. Nishimura, G. S. (Queen's Univ., Kingston, Ont.); Fidler, R. S.; Taylor, M. R.; Smith, R. W. Can. Met. Quart.; 8: No. 4, 319-22(Oct-Dec 1969).

The structure of the In–Zn eutectic was found to be broken lamellar, in agreement with calculated values of the solid-liquid interface roughness parameter. The conditions required to produce this structure are characterized. (auth) (Canada)

58287 TERNARY SYSTEM SILVER–INDIUM–ALUMINUM. Campbell, A. N.; Wagemann, R. (Univ. of Manitoba, Winnipeg). Can. J. Chem.; 48: No. 20, 3164-72(15 Oct 1970).

A number of alloys were examined microscopically. From these observations, from the equilibrium diagrams of the component binary systems, and from the application of the phase rule, a room temperature isothermal section was deduced. Three vertical sections through the ternary system were partially constructed from differential thermal analysis. These data show that invariant planes occur at 143, 148, 241, and 506°C. From the information obtained from the vertical sections and the room temperature isothermal section, isothermal sections were also proposed at 143 and 148°. The transformation at the 143°C invariant plane is a ternary eutectic, at 148° a ternary peritectic, and the other transformations at 241 and 506° are also ternary peritectics. Some evidence indicates that the ξ-phase of Ag–Al system and the γ-phase of Ag–In system link up through the ternary system forming a single phase region, and that such may also be the case with the phases μ and α' of the systems Ag–Al and Ag–In, respectively. The phases ϵ and ϕ of the system Ag–In do not appear to be capable of dissolving aluminum appreciably. (auth) (Canada)

58288 HEXAGONAL NETWORKS OF DISLOCATIONS IN α-ZIRCONIUM. Bedford, A. J.; Miller, D. R. (Univ. of Adelaide). J. Aust. Inst. Metals; 16: No. 3, 147-56(Sep 1971).

Several new mechanisms of formation of hexagonal networks of dislocations have been proposed to explain the observations of such networks in α-zirconium. The dislocations comprising the hexagonal networks all have Burgers vectors of the type $\langle 100 \rangle$ (or i.e., 1/3 $\langle 2\bar{1}\bar{1}0 \rangle$), but the networks are shown to be non-coplanar. Evidence is given to support the present proposals and to show that previously postulated mechanisms do not adequately explain the results of the present work. (auth)

58289 INFLUENCE OF YTTRIUM ON THE PHASE COMPOSITION OF VANADIUM–GALLIUM ALLOYS. Svechnikov, V. N.; Pan, V. M.; Spektor, A. Ts. (Inst. of Metallophysics, Kiev). Dokl. Akad. Nauk SSSR; 198: No. 2, 377-9(11 May 1971). (In Russian).

The portion of the ternary system V–Ga–Y bounded by the limits 47% Ga and 16% Y was investigated by preparing and testing 63 alloy samples. The solubility of Y in the compound V_3Ga was from 0.05 to 1%. α, β, γ, δ, and ϵ phases and their combinations are discussed. (K.S.W.)

58290 SYSTEM MOLYBDENUM–NICKEL–CARBON. Savitskii, E. M.; Zakharov, A. M.; Burkhanov, G. S.; Kataev, R. S. (Inst. of Metallurgy, Moscow). Izv. Vyssh. Ucheb. Zaved., Tsvet. Met.; No. 2, 91-4(1971). (In Russian).

The phase composition of alloys near the molybdenum corner of the Mo–Ni–C system was investigated, and the influence of nickel on the carbon solubility in Mo in the solid state was examined. The solidus temperature was obtained by differential thermal analysis, and with the use of a pyrometer. Isothermal profiles at 1800 and 1200°C were confirmed by microhardness and x-ray analysis. Adding Ni to Mo increases the solubility of C in the Mo; near 1800°C the solubility of C is raised from 0.04% to 0.07% by the introduction of 0.8% Ni. Adding Ni also noticeably lowers the solidus temperature of the Mo–C system and broadens the temperature interval of crystallization. (K.S.W.)

58291 NEW HIGH-TEMPERATURE PHASE OF PROTACTINIUM METAL. Asprey, L. B. (Los Alamos Scientific Lab., N. Mex.); Fowler, R. D.; Lindsay, J. D. G.; White, R. W.; Cunningham, B. B. Inorg. Nucl. Chem. Lett.; 7: No. 10, 977-80(Oct 1971).

On arc-melting a bead of very pure tetragonal Pa metal, using a water-cooled copper hearth, a new face-centered cubic structure with $\underline{a}_0$ = 5.02 Å was found, containing only a trace of the tetragonal phase. Flattening of the bead in a press resulted in reformation of the tetragonal phase, with only a small amount of the fcc form remaining. Re-examination of the x-ray photographs of a number of specimens taken earlier showed that some previously unexplained lines could have been due to this fcc phase. The metallic radius of the fcc form was 1.777 Å. (UK)

58292 CALCULATED LIQUIDUS AND SOLIDUS CURVES FOR THE Hf–Zr, Hf–U, AND Zr–U SYSTEMS. Chatterji, D. (Purdue Univ., Lafayette, Ind.). Met. Trans.; 2: No. 10, 2939-42(Oct 1971).

The solidus curves calculated from the published liquidus, using Steininger's approach, were compared with the published solidus curves for the Hf–Zr, Hf–U, and Zr–U systems. Excellent agreement was obtained for Hf–Zr and Hf–U, but not for Zr–U, indicating appreciable deviations from ideality. (D.L.C.)

58293 NATURE OF THE IMPURITY PHASE IN AN AGE-HARDENABLE Mg–10.8 WT. PERCENT Y ALLOY. Waldman, J.; Schwartz, M.; Perez, J. (Frankford Arsenal, Philadelphia). Met. Trans.; 2: No. 10, 2942-4(Oct 1971).

A study was made to identify the particles formed in Mg−Y alloys after solution heat treatment. Cast Mg−11 wt % Y plate was hot rolled and heat treated in the Mg-rich solid-solution phase field, and the Y content in the solid solution and particles was determined using an electron microprobe. The particles were identified as being Y_2O_3; this was confirmed by x-ray diffraction, and optical metallography was used to study the growth of Y_2O_3. It is concluded that when Mg−Y alloys are heated in air, oxidation to Y_2O_3 does occur below the surface. (D.L.C.)

Radiation Effects

58294 (BAW-10006(Rev.2)) REACTOR VESSEL MATERIAL SURVEILLANCE PROGRAM. (Babcock and Wilcox Co., Lynchburg, Va. Power Generation Div.). Sep 1971. 34p.

A surveillance program to determine the effects of neutron irradiation on changes in the nil-ductility transition temperature of reactor vessel materials is discussed. Charpy and tensile specimens, which are machined from as-fabricated metal, heat-affected-zone metal (HAZ), and weld metal, are placed in six surveillance capsules containing dosimeters and temperature monitors. The capsules are then placed in three holder tubes, which are positioned so that the capsules are near the peak axial neutron flux. (In the first few plants of this class, two thermal-aging capsules have been located in an area of essentially zero flux.) The holder tubes are attached to the thermal shield and can be installed and removed along with the internals core support assembly. Once the internals are installed, the holder tubes are rotated toward the vessel's wall and locked in place at favorable locations for irradiation of the specimens. Calculation results indicate that B&W's method is a reliable, conservative means of predicting peak neutron fluence. (auth)

58295 (FRNC-TH-64) EFFECT OF NEUTRON IRRADIATION ON THE HIGH TEMPERATURE MECHANICAL PROPERTIES OF AN AGE-HARDENED 80-20 Ni–Cr ALLOY. Maissin, Jacques (Nancy Univ. (France). Faculte des Sciences). 30 Jan 1970. 74p. (In French). Dep. NTIS (U. S. Sales Only). Thesis.

Radiation effects on an 80−20 Ni Cr alloy hardened by precipitation of $Ni_3(Ti, Al)\gamma'$ particles were studied. After reviewing bibliographic data on high temperature rupture mechanisms and radiation induced intergranular brittleness, the tensile tests effected are described. The study of helium distribution after irradiation allowed the results obtained from tensile experiments to be used in the study of embrittlement mechanisms due to helium. The effects of the alloy structure and its deformation behavior before irradiation were studied. (auth) (France)

58296 (HEDL-SA-196) MECHANICAL PROPERTIES OF FAST REACTOR IRRADIATED AUSTENITIC STAINLESS STEEL WELDMENT MATERIALS. Ward, A. L.; Blackburn, L. D.; Lovell, A. J. (Hanford Engineering Development Lab., Richland, Wash.). [nd]. 5p. (CONF-711009-4). Dep. NTIS.

From Joint meeting of the American Nuclear Society; Miami, Fla. (17 Oct 1971).

Pre- and postirradiation mechanical property results have been obtained on specimens taken from weldments representing four weld processes and three filler metals: submerged-arc, Type 308; shielded metal-arc, 16-8-2 (Cr-Ni-Mo); gas tungsten-arc, Type 308; and gas metal-arc, Type 308L. All welds were made in one inch thick Type 304 plate and contained from 3 to 10 percent (by volume) δ-ferrite. No strong difference is noted in the rupture life behavior between Type 304 base metal and weld metal in general in either the irradiated or unirradiated conditions. While there are variations in degree among the various weld processes, there is a consistent trend toward reductions in rupture life due to irradiation. The primary contributor to losses in rupture life is reduced ductility since both the Type 304 base metal and the weld metal as a class showed no consistent tendency to increased creep rates. The submerged-arc and the gas metal-arc weldments showed smaller reductions in rupture life largely because small decreases in creep rate served to offset a portion of the ductility loss. On the other hand, the gas tungsten-arc and shielded metal-arc weld metal exhibited somewhat higher postirradiation creep rates which, coupled with reduced ductility, led to more substantial losses in rupture life. Reduction in creep ductility without significant changes in creep rate, along with sharply reduced tensile ductility with disproportionately small strength increases, suggest that the elevated temperature helium embrittlement process controlled ductility losses. (auth)

58297 (HEDL-TME-71-72) BIAXIAL STRESS RUPTURE PROPERTIES OF ANNEALED 316 STAINLESS STEEL AFTER EBR-II IRRADIATION. Barker, R. W.; Holmes, J. J. (Hanford Engineering Development Lab., Richland, Wash.). Aug 1971. Contract AT(45-1)-2170. 22p. Dep. NTIS.

The effects of EBR-II irradiation on the biaxial stress-rupture properties of mill-annealed Type 316 stainless steel were investigated at test temperatures of 1000, 1200 and 1400°F. Tubular cladding specimens having a 0.208 inch diameter and 0.008 inch wall were irradiated in Row 7 to a total fluence of 1.2×10^{22} n/cm^2 at an irradiation temperature of 1050°F ± 100. The composition of the tubing was as follows: 0.081 C, 2.3 Mo, 1.5 Mn, 13.2 Ni, 17.0 Cr and 0.5 Si. EBR-II irradiation produces a loss in rupture strength and ductility at all test temperatures and an increase in average creep rate at 1000°F. Stress-to-rupture values were reduced by about a factor of $^1/_{40}$ at a test temperature of 1000; at 1200°F a loss of about a factor of $^1/_2$ occurred. At 1400°F, the reduction in strength was highly stress dependent, but reductions as great as a factor of $^1/_{10}$ were observed. Creep strain was reduced as much as a factor of $^1/_{25}$, depending on test temperature and test duration. The greatest losses in ductility occurred at 1000 and 1400°F, with less effect occurring at 1200°F. The loss in stress-rupture life observed in this work was found to be a function of both ductility and creep rate modifications resulting from irradiation. At 1000°F, the reduced ductility and increased average creep rate control the rupture life. At intermediate temperatures little change in creep rate or ductility occurs; thus, rupture life is not greatly affected by irradiation. However, at 1400°F, reduced ductility (due to helium embrittlement without creep rate changes) again produces substantial losses in rupture life. (auth)

58298 (ORNL-TM-3493) EFFECTS OF STRUCTURAL IMPERFECTIONS ON VOIDS IN ALUMINUM. Farrell, K.; Houston, J. T.; Wolfenden, A.; King, R. T.; Jostsons, A. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 20p. (CONF-710601-12). Dep. NTIS.

From International conference on radiation-induced voids in metals; Albany, N. Y. (9 Jun 1971).

Impurities, inclusions, dislocations, and grain boundaries are structural features that significantly influence the nature and distribution of voids in neutron irradiated aluminum. Preinjected hydrogen and helium are shown to increase the nucleation of voids for a given fluence without changing the swelling, whereas substitutional-type impurities retard void nucleation. Accelerated void development is frequently noted in the immediate vicinity of inclusions, and in some cases large, spherical shells of voids form around inclusions. Alongside grain boundaries there are regions denuded of voids and next to these are regions in which void formation is enhanced; at low irradiation temperatures these near-grain boundary regions contain more voids than the grain interiors, but at high irradiation temperatures they contain very much larger voids than elsewhere. A microstructure consisting of many fine precipitates and dislocations has a much improved resistance to void formation. (auth)

58299 (ORNL-TM-3495) VOID FORMATION IN NEUTRON IRRADIATED METALS. Stiegler, J. O. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 60p. (CONF-710601-13). Dep. NTIS.

From International conference on radiation-induced voids in metals; Albany, N. Y. (9 Jun 1971).

The characteristics of void formation in high-purity metals are reviewed and summarized in terms of irradiation and material variables. Fluence, irradiation temperature, flux and spectral effects, and the role of impurities are discussed. Results are compared and contrasted with those for stainless steel and evaluated in terms of proposed mechanisms for the nucleation and growth of voids. Although general trends of behavior are established for most of the experimental variables, exceptions are invariably found. The observations indicate that details of the damage structure are purity- and structure-sensitive. (auth)

58300 (ORNL-TM-3496) EFFECT OF ALLOYING AND PURITY ON THE FORMATION AND ORDERING OF VOIDS IN BCC METALS. Wiffen, F. W. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 22p. (CONF-710601-11). Dep. NTIS.

From International conference on radiation-induced voids in metals; Albany, N. Y. (9 Jun 1971).

The void populations in Mo, Nb, V, and one alloy of each of these were compared by electron microscopy. All three of the systems responded differently to the alloying. The void concentrations and sizes in the Mo and Mo−0.5% Ti irradiated at 790°C were identical within the measurement limits. After irradiation at 585°C the Mo−0.5% Ti contained more voids than the Mo, but the sizes were nearly identical. Alloying Nb with 1% Zr reduced the void concen-

XUM

tration after irradiation at 790°C by more than an order of magnitude, but this was compensated by an increase in void size. High void concentrations were observed in V irradiated at 385 to 600°C, but samples of V−20% Ti irradiated in the range 475 to 600°C had no detectable voids. The V−20% Ti contained high densities of irradiation-produced dislocations in networks and tangles. Voids in Mo, Mo−0.5% Ti, Nb, and Ta were ordered on a bcc superlattice parallel to the metal bcc lattice. Void ordering was not observable in the Nb−1% Zr or V. (auth)

58301 (RD/B/N-1971) ON THE LIMITATIONS OF THE METHOD OF LEAST SQUARES FOR THE TREATMENT OF CERTAIN TYPES OF DATA. Duckworth, F. C. (Central Electricity Generating Board, Berkeley (England). Berkeley Nuclear Labs.). Jul 1971. 16p. Dep. NTIS (U. S. Sales Only).

It is shown that the standard method of least squares is unsuitable for analyzing certain types of data, and particularly for data arising from the post-irradiation examination of fuel elements. It is suggested that a semi-subjective graphical technique may often give more useful results. (auth)

58302 MICROSTRUCTURAL ANALYSIS OF NEUTRON-IRRADIATED TITANIUM AND RHENIUM. Brimhall, J. L. (Battelle-Northwest, Richland, Wash.); Kulcinski, G. L.; Kissinger, H. E.; Mastel, B. Radiat. Eff.; 9: No. 3-4, 273-8(Jun 1971).

The defect structure in α-titanium and rhenium irradiated with neutrons at 0.4 T_m (T_m = absolute melting temperature) has been analyzed using transmission electron microscopy. In rhenium, the vacancies agglomerate into voids whereas in titanium, vacancy dislocation loops lying on the prism planes are the only vacancy-type defects observed. In both metals, dislocation segments and network fragments are the main evidence of interstitial-type defects. The presence of dislocation loops rather than voids in titanium irradiated at this temperature is an anomalous result when compared to results on other similarly irradiated pure metals. Possible explanations for the preferential formation of loops rather than voids in the titanium are discussed. (auth)

58303 EFFECT OF IMPURITIES WITH A NEGATIVE SIZE EFFECT ON THE RECOVERY OF ALUMINUM IRRADIATED WITH FAST NEUTRONS AT 78°K. Dimitrov, C.; Moreau, F.; Dimitrov, O. (Centre National de la Recherche Scientifique, Vitry-sur-Seine, France). Compt. Rend., Ser. C; 273: No. 1, 1-4(5 Jul 1971). (In French).

The presence of low amounts of chromium, copper, or vanadium in irradiated aluminum increased the stage III recovery. This behavior was in good agreement with the model of elastic interactions between impurities and the radioinduced interstitial defects. The effects of titanium additions were not explained by this model. (auth)

58304 VOIDS FORMED BY IRRADIATION OF REACTOR MATERIALS. Proceedings of the British Nuclear Energy Society, European Conference Held at Reading, England, March 24–25, 1971. Pugh, S. F.; Loretto, M. H.; Norris, D. I. R. (eds.). London; British Nuclear Energy Society (1971). 365p. £7.50. (CONF-710330).

Thirty-three papers are included which covered various topics relating to void production by fast neutrons, quenching, ion bombardment, high-voltage electron microscopy; theory of void formation; and nucleation of voids. A separate abstract was prepared for each paper. (D.L.C.)

For abstracts of individual papers see: 58305–58336 and 59145.

58305 FAST NEUTRON INDUCED VOIDAGE IN NON-FISSILE METALS AND ALLOYS: A REVIEW. Bagley, K. Q.; Bramman, J. I.; Cawthorne, C. (United Kingdom Atomic Energy Authority, Dounreay, Scotland). pp 1-26 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The discovery of prolific void formation in stainless steels under fast neutron irradiation was first reported in 1966 and was quickly followed by accounts of its appearance in other metals and alloys. Recognition of the implications of the phenomenon on fast reactor design and operation have led to intensive research in many countries into the nature of void nucleation and growth processes and the magnitude of consequent dimensional changes in potential fast reactor cladding and structural materials. In this work, reliance was placed principally on transmission electron microscopy for the study of void incidence and morphology, on immersion density and linear dimensional measurements for the evaluation of macroscopic effects. Volume changes in excess of 5% were recorded in stainless steels, which by virtue of their great technological interest attracted most attention. In addition, work was published on the generation of voids in nickel, iron, aluminium, molybdenum, tungsten, vanadium, zirconium, titanium, rhenium, and copper. Data on the influence of such factors as neutron fluence, irradiation temperature, compositional and structural variables on void development and stability are reviewed. (auth)

58306 DENSITY CHANGES IN CLADDING MATERIALS IRRADIATED IN DFR. Bramman, J. I.; Bagley, K. Q.; Cawthorne, C.; Fulton, E. J.; Sinclair, W. D. J. (United Kingdom Atomic Energy Authority, Dounreay, Scotland). pp 27-33 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Density changes in four stainless steels (AISI M316 and M316L, FV548 and EN58B) and in a Nimonic alloy (PE16), due to voidage induced by fast neutron irradiation to fluences up to 8.7×10^{22} n. cm^{-2} in the temperature range 300 to 650°C, were shown to be very sensitive to small differences in composition and pre-irradiation condition. It was found that the data for a given material, condition, and irradiation temperature can be adequately represented by assuming a linear change in density with increasing displacement dose after a threshold. The work described shows that each material has a characteristic temperature dependence of swelling, though this is not susceptible to expression in analytical form. (auth)

58307 ELECTRON MICROSCOPE OBSERVATIONS OF VOIDS IN CLADDING MATERIALS IRRADIATED IN DFR. Cawthorne, C.; Fulton, E. J.; Bramman, J. I.; Linekar, G. A. B.; Sharpe, R. M. (United Kingdom Atomic Energy Authority, Dounreay, Scotland). pp 35-43 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Transmission electron microscopy was used in studies of void formation in a variety of cladding materials (M316, M316L, and FV548 stainless steels and Nimonic PE16) irradiated to fluences of up to $8.7 \times 10^{22} n.cm^{-2}$ in DFR, permitting the effects of fluence and irradiation temperature on void size and number density to be investigated. There are striking differences in the annealing behavior of various types of void population. (auth)

58308 EFFECT OF STRESS DURING IRRADIATION ON VOID FORMATION IN NICKEL. Barton, P. J.; Nutter, P. H. (Atomic Energy Research Establishment, Harwell, Eng.). pp 45-9 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

An experiment is described which is aimed to investigate the dependence upon uniaxial tensile stress of void formation in neutron-irradiated nickel. Irradiations were carried out to a dose of $3.6 \times 10^{24} n.m^{-2}$(fission) at 500°C and at stresses of 0.23, 5.38, and 17.24 MN m^{-2}. Although only preliminary structural data are available, it may be concluded that over this range of values void size is independent of stress and that void concentration is not markedly stress-sensitive. (auth) (UK)

58309 SOME ELECTRON MICROSCOPE OBSERVATIONS ON VOIDS IN VANADIUM, NIOBIUM, AND MOLYBDENUM. Elen, J. D. (Reactor Centrum Nederland, Petten, Netherlands). pp 51-62 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Samples of pure vanadium, niobium, and molybdenum were irradiated at three temperatures in the High Flux Reactor. Fast neutron fluences were $2.2 \times 10^{20} n/cm^2$ to $5.5 \times 10^{20} n/cm^2$ and temperatures covered the range of 0.25 T_m to 0.47 T_m. Some vanadium−2.8% titanium alloy samples were included. In all samples of the pure metals, voids were observed. Their size increased with irradiation temperature from 25 Å at 0.25 T_m to about 120 Å at 0.47 T_m. The logarithmic plot of the void densities, combined for the three metals, was found to decrease linearly with T/T_m over the range of $5 \times 10^{16}/cm^3$ to $1 \times 10^{14}/cm^3$. The thermal stability of the voids, produced at the lower irradiation temperature, was studied by 1-hr isochronal annealing series. Up to 0.45 T_m, larger voids grew at the expense of smaller ones, followed by rapid disappearance. Only a few voids were observed in the alloy. This is discussed in terms of dislocation damage distribution. (auth)

58310 FAST NEUTRON IRRADIATION OF Al, Mg, AND Cu. Levy, V.; Mathie, J.; Risbet, A.; Levy, R.; Poirier, J. P.

(CEN, Saclay, France). pp 63-9 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Results on void formation in Al, Mg, and Cu under fast-neutron irradiation are presented. The effects of different parameters were investigated e.g., temperature, dose, cold work, and impurity effects. (auth)

58311 EFFECT OF NEUTRON DOSE ON VOID FORMATION IN HIGH PURITY ALUMINUM. Packan, N. H. (IMF, Karlsruhe, Ger.). pp 71-8 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Transmission electron microscopy was used to investigate the fluence and flux dependence of void formation in pure aluminum. Voids observed resulted from neutron exposures ranging from 1.5×10^{19} to 1.6×10^{22} neutrons/cm^2 ($E > 0.1$ MeV), at a common irradiation temperature of 55 ± 5°C (0.35 T_m). By 10^{22} neutrons/cm^2, the voids ranged up to 1000 Å in diameter and comprised a total volume fraction of 7.4%. The mean void size was found to increase in proportion to the irradiation time raised to the one-sixth power. The void concentration increased rapidly at first but eventually approached saturation; expressed as a power relation, $N \sim (\phi t)^a$, the exponent decreased from 2.0 initially to 0.1 at the highest fluence studied. The void volume fraction was also found proportional to the fluence raised to a variable power, the value decreasing from roughly $5/2$ to $1/2$ over this range of fluence. These observations are compared with several current models for void formation. Irradiation at an order-of-magnitude lower flux resulted in changes in the void morphology (e.g., half as many, but larger and more frequently elongated voids) much like those resulting from irradiation at a higher temperature. Either case results in a lower in-reactor vacancy supersaturation, which in turn could be the cause of the void morphology changes. No difference in the void population was evident in material degassed prior to irradiation, when compared with similarly irradiated as-received material (containing 15 to 20 atomic ppM hydrogen). (auth)

58312 THEORY OF VOID GROWTH IN IRRADIATED MATERIALS. Bullough, R.; Perrin, R. C. (Atomic Energy Research Establishment, Harwell, Eng.). pp 79-107 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The theory of void growth in irradiated materials is reviewed and correlated, where appropriate, to the available accelerator measurements in nickel and steel. The dependence of the void growth on the various physical parameters is emphasized; these include dose, dose rate, void density, dislocation density, precipitate (coherent and incoherent) density, and temperature. The various ways in which the swelling problem can be alleviated are discussed. (auth)

58313 VOID LATTICE IN MOLYBDENUM. Malen, K.; Bullough, R. (Atomic Energy Research Establishment, Harwell, Eng.). pp 109-19 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

A theoretical explanation for the recently observed void lattice in molybdenum is presented. The void lattice is observed to be precisely parallel to the underlying molybdenum atomic lattice and therefore it is conjectured that its existence must be a direct consequence of the elastic cubic anisotropy of the molybdenum matrix. Using the theory of anisotropic elasticity, a noncentral pairwise void–void interaction energy is deduced in terms of various invariant derivatives of the appropriate Green's tensor and used to discuss the energy and equilibrium spacing of the void lattice. (auth)

58314 TEMPERATURE RANGE AND DOSE DEPENDENCE FOR VOID GROWTH IN IRRADIATED MATERIALS. Foreman, A. J. E. (Atomic Energy Research Establishment, Harwell, Eng.). pp 121-32 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The rate of growth of voids during irradiation was determined from a calculation of the small disparity between the rates of diffusion of the interstitial atoms and vacancies to the voids. The driving force is taken to be the slightly preferential trapping of the interstitial atoms at dislocations, as suggested by Greenwood, Foreman and Rimmer (1959). The continually changing nature of the dislocation structure during an irradiation is represented by the continuum sink model. The temperature range for void growth can be understood in terms of a "phase diagram" showing the region of void growth as a function of temperature and sink density. The peak swelling in this range was calculated for constant dislocation densities and for a steadily increasing dislocation density (loop growth). The effect of a zone denuded of dislocations close to the void surface was also considered. The predicted dose dependence of the swelling is affected by the relative densities of the voids, dislocations, and precipitate particles, and lies in the range $(\text{dose})^{1.0}$ to $(\text{dose})^{2.0}$ in many cases. It is shown that the preferential trapping of interstitial atoms at the void surface would produce unusual void shrinkage effects, which could affect the void nucleation stage. (auth)

58315 INTERACTION BETWEEN A VOID AND A DISLOCATION LOOP. Willis, J. R.; Bullough, R. (Atomic Energy Research Establishment, Harwell, Eng.). pp 133-47 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The interaction between a pure edge dislocation loop and a spherical void was calculated and used to discuss the modes of glide and climb that can lead to dislocation depletion in the vicinity of the void. (auth)

58316 THEORETICAL MODEL FOR VOID FORMATION IN THE HIGH VOLTAGE MICROSCOPE. Fisher, S. B.; Williams, K. R. (Central Electricity Generating Board, Berkeley, Eng.). pp 149-57 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Observations made of the changing microstructure during void growth in the HVEM have led to the proposition of a simple theoretical model to describe the growth. Void formation is shown to be dominated by the increase in interstitial sink density as a result of interstitial loop growth under irradiation. This causes a time-dependent decrease in interstitial concentration and a corresponding increase in vacancy concentration. On impingement of the dislocation loops, mutual annihilation results in a loss of interstitial sink density at a rate dependent on dislocation movement and hence beam flux. It is this latter effect which results in a limitation to the void growth rate in annealed material. The difficulties in extending the theory to the case of neutron irradiation are discussed, and methods for swelling limitation arising from the model are examined in some detail. (auth)

58317 FORMATION AND BEHAVIOUR OF QUENCHED-IN VOIDS IN CLOSE PACKED METALS. Smallman, R. E.; Westmacott, K. H. (Univ. of Birmingham, Eng.). pp 159-76 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The observation of voids produced in fcc and hcp metals by quenching is discussed and attention drawn to the role of impurity atoms, particularly hydrogen, in the nucleation process. The behavior of voids on annealing is also considered and a comparison made between voids and cavities containing gas. (auth)

58318 VOIDS IN THE INTERMETALLIC COMPOUND NiAl. Fraser, H. L. (Univ. of Birmingham, Eng.); Loretto, M. H.; Smallman, R. E.; Wasilewski, R. J. pp 177-82 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Large single crystals of nominally stoichiometric NiAl were sectioned and examined using transmission electron microscopy. Large voids up to 1100 Å in diameter were observed and it was shown that the faces of these voids are $\{110\}$ and $\{100\}$ planes. Measurements carried out on symmetrical voids have shown that the ratio of surface energies of the $\{100\}$ planes and $\{110\}$ planes is given by $\gamma 100/\gamma 110 = 1.10$. Annealing experiments carried out on bulk specimens result in the formation of voids elongated along $\langle 100 \rangle$ directions as well as voids which are symmetrical. The significance of these results is discussed in terms of the mobility of the high concentration of thermal vacancies in NiAl. (auth)

58319 FORMATION OF VOIDS BY QUENCHING OR DEFORMATION OF METALS. Erich, Ruedl (CCR–EURATOM, Ispra, Italy). pp 183-90 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Earlier studies of voids in quenched platinum are discussed and more recent work on voids in deformed aluminum containing alumina particles described. Polygonal voids of diameters up to several hundred Å, produced by the aggregation of frozen-in vacancies, were observed in quenched Pt foils. The voids disappeared on annealing at 800°C. The voids were possibly stabilized by dissolved gas. Lenticular voids formed by interface failure, were observed at particles in deformed Al foils. With continued straining, the voids elongated in the direction of the tensile axis and occasionally were pinched off in regions of highly localized deformation. Preliminary annealing studies indicated that the voids change neither shape nor size on annealing at 400°C for $\frac{1}{2}$ hr. (auth)

58320 VOID FORMATION DURING ION IRRADIATION OF METALS AT ELEVATED TEMPERATURES. Nelson, R. S.; Mazey, D. J.; Hudson, J. A. (Atomic Energy Research Establishment, Harwell, Eng.). pp 191-203 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The technique of simulating fast-neutron damage in metals by ion bombardment is discussed. The conditions necessary for obtaining quantitative design data are reviewed together with an outline of more qualitative experiments designed to elucidate the fundamental processes. A selection of results is presented to illustrate the usefulness of the technique. (auth)

58321 TEMPERATURE DEPENDENCE OF VOID SWELLING IN TYPE 316 AUSTENITIC STAINLESS STEEL IRRADIATED WITH 20 MeV C^{++} IONS. Williams, T. M. (Atomic Energy Research Establishment, Harwell, Eng.). pp 205-12 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Foils of Type 316 stainless steel containing 10^{-5} helium were irradiated to a dose of 3×10^{17} ions/cm^2 at temperatures in the range 400 to 700°C using 20-MeV C^{++} ions from the Harwell Variable Energy Cyclotron. This ion dose produced an estimated maximum of 40 displacements/atom at 6.6 μm below the ion-incident surface. The void volume at each temperature was determined by transmission electron microscopy. In solution-treated Type 316 steel, the void swelling reached a maximum of 12% at 600°C for a dose of 40 displacements/atom. In 20% cold worked Type 316 steel irradiated to the same dose, the highest swelling (9.5%) was at the highest temperature employed. (auth)

58322 VOID FORMATION IN NICKEL, 316 STEEL, AND NIMONIC PE16 DURING 20 MeV C^{++} IRRADIATION. Hudson, J. A.; Mazey, D. J.; Nelson, R. S. (Atomic Energy Research Establishment, Harwell, Eng.). pp 213-21 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Nickel, 316 stainless steel, and Nimonic PE 16 foils containing 10^{-5} He, were bombarded at 525°C by 20-MeV C^{++} ions in the Harwell Variable Energy Cyclotron. Void swelling was determined by transmission electron microscopy for damage doses up to 400 d/atom in nickel and steel and 280 d/atom in PE 16. Dislocation density and other features were also investigated together with the effect of prior cold-work (20%) in 316 steel. Swelling in nickel varies as a linear function of dose up to 6% at 40 d/atom. The swelling rate then falls to give 15% swelling at 350 d/atom. In 316 steel, voids and dislocation loops are first observed at about 2 d/atom after which the swelling varies approximately as $(\text{dose})^2$. At 40 to 50 d/atom, the swelling rate decreases and the swelling versus dose curve merges with that for nickel. Void nucleation in nickel occurs at an early stage and swelling is predominantly by void growth. However, in 316 steel up to about 20 d/atom, the increase in swelling is due to an increase in both void size and void concentration; above 20 d/atom, void growth and coalescence dominate the kinetics. In general, swelling in PE 16 is much less than in nickel or steel, possibly due to enhanced recombination and the interaction of the radiation-induced dislocation structure with the coherent γ' precipitates within the matrix. (auth)

58323 TEMPERATURE DEPENDENCE OF VOID SWELLING IN 18/8/Ti STEEL. Walters, G. P. (Atomic Energy Research Establishment, Harwell, Eng.). pp 223-30 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The Harwell Variable Energy Cyclotron was used to produce voidage in solution treated and 20% cold worked 18/8/Ti steel in the temperature range 450 to 700°C. All specimens were initially bombarded with α particles at ambient temperature to introduce a uniform concentration of helium (10^{-5} atoms/atom) throughout. This was followed by irradiating with 20-MeV carbon ions at 450, 525, 550, 600, 650, and 700°C to a constant dose of 4.5×10^{17} ions/cm^2 (60 displacements/atom in the peak damage region). Swelling was calculated from void counts taken from electron micrographs. Swelling in both the solution-treated and 20% cold-worked condition was markedly temperature-dependent, the dependency being less for the cold-worked steel. Cold working produced a beneficial effect at all temperatures up to 650°C; however, at 700°C the swelling was similar to the solution treated steel. (auth)

58324 EFFECT OF COLD WORK ON THE SWELLING OF TYPE 316 STEEL IRRADIATED WITH 20 MeV CARBON IONS AT 525^{0}C. Walters, G. P. (Atomic Energy Research Establishment, Harwell, Eng.). pp 231-37 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Since it had been shown that cold working can reduce the swelling of neutron-irradiated stainless steel, experiments using the Harwell Variable Energy Cyclotron were carried out to doses higher than those previously examined. Solution treated, 10%, 20%, and 40% cold-worked specimens containing 10^{-5} atoms/atom of helium were irradiated with 20-MeV carbon ions at 525°C to a dose of 3×10^{17} ions/cm^2 (40 displacements/atom in the peak damage region) or 1.5×10^{18} ions/cm^2 (200 displacements/atom). Electron microscopy showed that swelling at the lower dose was reduced slightly at all levels of cold work. However, at the higher dose only 40% cold work appeared to produce any significant reduction. It is considered that at doses not much greater than 200 displacements/atom, cold working (up to 40%) will cease to be beneficial. (auth)

58325 PRODUCTION OF VOIDS IN COBALT DURING ION BOMBARDMENT AND ELECTRON IRRADIATION. Manthorpe, S. A.; Buckley, S. N. (Atomic Energy Research Establishment, Harwell, Eng.). pp 239-46 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

A study was made of voids generated in the hcp and fcc phases of cobalt during 100-kV carbon-ion bombardment and electron irradiation in a 1-MV electron microscope. The results are incompatible with the dislocation preference hypothesis and were explained by a new model of void growth based on the differential velocity of vacancy and interstitial diffusion to glissile dislocations. (auth)

58326 SIMULATION OF FAST REACTOR IRRADIATION EFFECTS IN THE HIGH VOLTAGE ELECTRON MICROSCOPE. Norris, D. I. R. (Berkeley Nuclear Labs., Eng.). pp 247-68 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

A review is given of the basic characteristics of void growth in metals irradiated by the electron beam of a high-voltage electron microscope. This technique for simulating fast reactor effects has the advantage of permitting observations during irradiation. The relative simplicity of electron irradiation is valuable for void nucleation experiments. In nickel, it is found that implanted gas concentration is a controlling factor. Direct experimental evidence was obtained for dislocations acting as preferential sinks for interstitials, so promoting void growth. With increasing irradiation temperature, the void concentration decreases and the void size increases. The upper part of the temperature range for void growth is inaccessible because of surface effects. Void concentrations are reduced near surfaces and incoherent boundaries. The technique can be used quantitatively to determine the dose dependence of void swelling. In nickel, three stages are distinguished and are correlated with the development of the irradiation-induced dislocation structure. The observed swelling rates suggest that collision cascades are not important in void growth. (auth)

58327 PRODUCTION OF VOIDS IN COPPER BY ELECTRON IRRADIATION IN A 1 MV ELECTRON MICROSCOPE. Makin, M. J. (Atomic Energy Research Establishment, Harwell, Eng.). pp 269-74 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Experiments were made on the formation of voids in copper during electron irradiation in a 1-MV electron microscope. The results described include the effects of dose, temperature, inert gas injection, alloying, temperature increases, annealing, gas bubbles, and neutron-produced voids. A model of void growth in high dose rate conditions is described in which voids grow as a result of the difference between the preference of interstitials for dislocations and voids. The void preference was demonstrated experimentally. Using the model it is shown that fairly accurate predictions can be made of the rate of swelling in given conditions provided the dislocation and void densities are known. (auth)

58328 GROWTH OF INTERSTITIAL AND VACANCY AGGLOMERATES IN NICKEL DURING ELECTRON IRRADIATION. Urban, K. (Max-Planck-Institut fuer Metallforschung, Stuttgart). pp 275-82 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Results are presented of investigations of the growth of defect agglomerates in nickel during electron irradiation at high temperatures in a Hitachi high-voltage electron microscope. In high-purity samples, the formation of interstitial dislocation loops was observed during irradiation at temperatures between 20 and 550°C. In an intermediate temperature region from about 200 up to 420°C, vacancy dislocation loops were also observed. The interaction of both types of loops provides clear evidence that in the stress field of edge dislocations, Frenkel defects are separated and that at edge dislocations interstitials are absorbed preferentially. Such preferential absorption is shown to be necessary for void growth. Voids only grew in samples containing impurities. The formation of voids was observed during irradiation at temperatures from 280 up to about 600°C. They annealed out completely at 730°C within 3 to 4 hours. (auth)

58329 GROWTH OF VOIDS IN STAINLESS STEEL. Buswell, J. T. (Berkeley Nuclear Labs., Eng.). pp 283-91 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Voids were grown in stainless steel foils by in-situ irradiation with 1-MeV electrons in a high-voltage electron microscope. Voids were produced during irradiation in the temperature range 450 to 600°C. The voids were generally octahedral in shape. The frequency of occurrence of voids increased with, and their size decreased with, the concentration of pre-injected helium. However, the presence of helium was not essential for void formation. The volume swelling ($\Delta V/V$) increased with an increase in the helium content. Volume changes in the range 0 to 2% were obtained. In this range $\Delta V/V \propto \text{dose}^2$. The characteristics of the nucleation and growth of voids, and the influence on those factors of the presence of precipitates, etc., are discussed. (auth)

58330 INFLUENCE OF HVEM IRRADIATION ON NEUTRON INDUCED VOIDS IN NICKEL. Harbottle, J. E. (Berkeley Nuclear Labs., Eng.). pp 293-300 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Pure nickel foils, previously irradiated by fast neutrons to doses between 2×10^{18} and 1×10^{20} cm^{-2} at temperatures of 50, 400, and 450°C were electron irradiated in the HVEM between 400 and 450°C. In this way the subsequent growth and shrinkage of voids under the influence of electron irradiation was studied in situ. For neutron doses $\geq 5 \times 10^{19}$ cm^{-2}, where observable voids are produced, the initially uniform distribution throughout the foil is modified by electron irradiation due to the surface denuded layers. Void growth occurs in a central region of thickness given by the ratio of the void concentrations and is correlated with their morphology as a function of electron dose. Initially $\{111\}$ octahedral voids convert by progressive $\{110\}$ truncations to a cubic shape, the transition coinciding with the onset of linear growth. The reduced void volume fraction increases linearly with displacement dose up to 9% at 45 d/a. Voids were grown by electron irradiation following low neutron doses $\sim 10^{18}$ cm^{-2} at 50°C, indicating that the transmuted helium concentration ($<10^{-6}$ at. %) necessary for nucleation is very low, and that the distribution of the gas is important. (auth)

58331 SIGNIFICANCE OF FAST NEUTRON INDUCED VOIDS IN THE DESIGN AND PERFORMANCE OF FAST REACTORS. Bishop, J. F. W. (United Kingdom Atomic Energy Authority, Risley, Eng.). pp 301-18 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Although void swelling is not a significant feature in the performance of existing fast reactors there are clear indications that at the higher temperatures and higher fast neutron fluences in projected power reactors the magnitude of void swelling will be such as to affect either the design of the core, the operational procedures, or choice of materials. The data areas on void formation are reviewed and evaluated and the need for extrapolation is discussed. Conditions of exposure for the various core components in power reactors are considered in relation to performance requirements. Alternative core concepts and design criteria are described, and the importance of radiation creep in limiting internal stresses is emphasized. (auth)

58332 COMPARISON OF THE DAMAGE STRUCTURE IN FAST REACTOR AND ACCELERATOR IRRADIATED MOLYBDENUM. Eyre, B. L.; Evans, J. H. (Atomic Energy Research Establishment, Harwell, Eng.). pp 323-31 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Transmission electron microscopy was used to compare the structures of molybdenum irradiated with 2-MeV nitrogen ions in an accelerator at 870°C with similar material neutron-irradiated in the fast reactor at 650°C. The observations in the latter case confirmed the accelerator results where it was found that the voids aligned themselves into a regular array having body-centred cubic symmetry with crystallographic axes identical with those of the host lattice. The various features of the two sets of observations are discussed with the similar swelling at the widely separated irradiation temperatures being explained by the displacement rate difference. Reference is made to the theoretical explanation for the void lattice by Malen and Bullough (1971) and the possible practical importance of the lattice is indicated. (auth)

58333 CONTRIBUTION TO THE DISCUSSION ON NUCLEATION. Harbottle, J. E. (Berkeley Nuclear Labs., Eng.). pp 333 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Nickel foils, neutron irradiated to doses of $\sim 10^{18}$ cm^{-2} at 50°C, were irradiated by 1-MeV electrons in the HVEM and voids were observed to grow to a density of $\sim 10^{12}$ mm^{-3}. The concentration of transmuted helium ($\sim 10^{-6}$ at. %) is about the same as the intrinsic gaseous impurity of 4N5 purity nickel, yet only interstitial loops and not voids are grown on electron irradiation of pure nickel, possibly due to the low dislocation density in annealed material providing insufficient sinks for the interstitials. The similarities in void densities over a wide range of transmuted helium concentrations together with the fact that voids cannot be grown by electrons alone in 4N5 nickel suggest that the formation of void nuclei is controlled more by the relative distribution of gas atoms and their relationship with defects than by their quantity. (UK)

58334 KNOCK-ON OF GAS ATOMS INTO MATERIALS DURING IRRADIATION IN A GAS ATMOSPHERE. Migge, H. (Hahn-Meitner-Inst., Berlin). pp 335-6 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).
From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

The He content of silver foils of different thickness after irradiations under 600 torr He at 80°C is given. The fast fluence ($E > 0.1$ MeV) was 4×10^{17}/cm^2. The He content per cm^2 surface area of the sample increased linearly with increasing foil thickness up to a saturation value of 1.6×10^{12}/cm^2 at about 10^4 Å. From the constant initial slope of the curve, the He concentration was calculated to be 1.7×10^{16}/cm^3. The concentration fell quickly to zero at thicknesses $>10^4$ Å. An interpretation of the results is given. (UK)

58335 SOME OBSERVATIONS OF THERMAL RELEASE OF HELIUM FROM IRRADIATED NICKEL. Bergenlid, U.

XUM

(Aktiebolaget Atomenergi, Stockholm). pp 337-8 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Slightly boron-doped nickel specimens were irradiated to the order of 10^{20} n/cm^2 and the thermally activated release of helium measured. Results indicated that vacancy currents provide a mechanism for the transport of helium. A diagram is given showing the release rate peaks at each resistivity recovery stage. (UK)

58336 NEW SOURCE OF HELIUM IN CLADDING MATERIALS. Birss, I. R.; Ellis, W. E. (United Kingdom Atomic Energy Authority, Sellafield, Eng.). pp 339-45 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

Recent measurements have shown unexpectedly high helium contents in cladding materials irradiated in thermal reactors, and the reaction $^{58}Ni(n,\gamma)^{59}Ni(n,\alpha)^{56}Fe$ was suggested to explain the effect. A cross section was derived for the second part of the reaction, and it was shown that the reaction rate is not significant either in DFR or PFR. (auth)

58337 DYNAMIC DISLOCATION PILE-UP IN NEUTRON-IRRADIATED METALS. Arsenault, R. J. (Univ. of Maryland, College Park). Phil. Mag.: 24: No. 188, 259-71(Aug 1971).

The formation of a dislocation pile up was examined for the condition where there is a finite removal probability of the short-range barriers to dislocation motion. The purpose of investigating this type of dynamic pile up formation was to determine whether the rapid rate of slip-line formation in neutron-irradiated metals could be a thermally activated process. The evidence obtained affirms the possibility of having slip lines form rapidly while the process is still thermally activated. (auth)

58338 ANELASTIC PROPERTIES OF IRRADIATED ALUMINUM COLD-WORKED AT LOW TEMPERATURE. Guenin, G.; Perez, J.; Gobin, P. F. (Institut National des Sciences Appliquees, Villeurbanne, France). Radiat. Eff.; 10: No. 1-2, 17-25(Jul 1971). (In French).

The influence of cold-work and of subsequent annealing on the anelastic properties of aluminum has been studied by several workers. The behavior of the cold worked metal can be analyzed in terms of elementary processes such as: Niblett and Wilks peak (B_1) and Bordoni peak (B_2); and the P_A, P_B, and P_C peaks due to the interaction between dislocations and point defects. Some effects due to additional point defects induced by neutron irradiation at 80°K prior to the plastic deformation are presented. Those effects can be summarized as follows. Niblett and Wilks peak (B_1) does not appear any more; by comparison with unirradiated aluminum, the Bordoni peak (B_2) on one hand is lower, and on the other hand increases more after an anneal at 220°K. The period anomaly $\Delta T/T_0$ is weaker in the whole spectrum and particularly at 10°K. Above 200°K, it increases (reversibly) until 300°K. A peak similar to the P_C peak of unirradiated aluminum is observed during the first temperature increase but this peak is annealed during observation. These results have been interpreted with the following assumptions: The B_1 and B_2 peaks are due to intrinsic properties of dislocations; $\Delta T/T_0$ is induced by the movement of geometrical kinks at low temperature (<100°K) and by break-away of dislocations at high temperature (between 200 and 300°K); and the peak observed near room temperature is a consequence of thermomechanical unpinning of dislocations from irradiation induced point defects. (auth)

58339 LOW TEMPERATURE DEFORMATION CHARACTERISTICS OF NEUTRON IRRADIATED VANADIUM–TITANIUM ALLOYS. Pink, E.; Arsenault, R. J. (Univ. of Maryland, College Park). Contract AT(40-1)-3612. Radiat. Eff.; 10: No. 1-2, 27-32(Jul 1971).

An investigation was undertaken to determine the effects of neutron irradiation on the low temperature deformation characteristics of vanadium–titanium alloys. The effects can be divided into two groups: for low titanium concentrations (0.75 and 1.6 wt % Ti) a weakening effect appeared which was apparent for the complete temperature range investigated for the 0.75% Ti but to a lesser extent for the 1.6% titanium alloy. For alloys with higher titanium concentration (4 to 20% Ti), the neutron irradiation did not affect the thermal component of the yield stress, i.e., no change in the rate-controlling mechanism of low temperature deformation occurred. For both alloy groups the neutron damage resulted in an increase in the athermal component of the yield stress. (auth)

58340 OBSERVATIONS OF A REGULAR VOID ARRAY IN HIGH PURITY MOLYBDENUM AND T.Z.M. IRRADIATED AT HIGH TEMPERATURES WITH 2 MeV NITROGEN IONS. Evans, J. H. (Atomic Energy Research Establishment, Harwell, Eng.). Radiat. Eff.; 10: No. 1-2, 55-60(Jul 1971).

Electron microscope observations are presented to demonstrate the existence of a three-dimensional defect array in high purity molybdenum, and in TZM irradiated at high temperatures with 2-MeV nitrogen ions to doses of approximately 10^{18} ions/cm^2. It was found that the defect array has a body centered cubic structure with a lattice parameter of 220 Å and with crystallographic axes coincident with those of the molybdenum matrix. The identification of the defects as voids is discussed together with possible mechanisms for the array formation. (auth)

58341 COMPLEX ANNEALING WITHIN STAGE I OF ALUMINUM. Chaplin, R. L. (Clemson Univ., S. C.). Radiat. Eff.; 10: No. 1-2, 61-4(Jul 1971).

Irradiating aluminum with 0.4 MeV electrons gave a component of damage which annealed in the 21 to 26 K temperature region that was independent of the I_B and I_C annealing stages. A detailed study has been made that proves this component of the damage is reproducible, increased with increasing irradiation energy, increased when aluminum is doped with copper, independent of crystallographic orientation, independent of irradiation dose, and also present from 27 to 29°K. It is proposed that this continuum type of recovery is caused by the annealing of point defects which reside at strained regions of a crystal. (auth)

58342 EFFECT OF NEUTRON IRRADIATION ON MECHANICAL PROPERTIES OF RHENIUM. Pitt, C. H.; Brimhall, J. L. (Battelle-Northwest, Richland, Wash.). Radiat. Eff.; 10: No. 1-2, 71-7(Jul 1971).

Polycrystalline and single crystal rhenium tensile specimens have been neutron irradiated at 50°C to fluences up to 2.6×10^{19} n/cm^2 and subsequently tested in tension. The microstructure of the single crystals was examined by transmission electron microscopy. The yield strengths of the polycrystalline specimens increased from 19,000 psi in the unirradiated material to 143,000 psi after a fluence of 2.6×10^{19} n/cm^2. Slip was observed on the basal and prismatic planes and $(11\bar{2}1)$ twinning was found to be the main twinning mode in the single crystals. The single crystal yield strengths also increased markedly with fluence and were found to increase at a greater rate in those crystals oriented for prismatic slip. The radiation damage greatly retarded twin growth at the higher fluences but did not appear to affect twin nucleation. Channeling of dislocation through the small defect clusters occurred in the irradiated specimens. Deformation twinning did not result in channeling type behavior although anomalous channels parallel to, but outside, the twins were observed. (auth)

58343 HEAT TREATMENT STUDIES OF IR ABSORPTION IN REACTOR-IRRADIATED GERMANIUM. Lin, K. C.; Chu, C. N.; Loh, S. Y.; Cheng, Y. C. Nucl. Sci. J. (Taiwan); 8: No. 1, 1-11(Apr 1971). (In Chinese).

The effects of transmutation-produced impurities (Ga, As, Se) and displaced atoms in germanium induced by nuclear reactor irradiation on infrared absorption were investigated by heat treatment. It was found that upon isochronal annealing in the temperature range between 50 and 500°C, two regions in which a marked decrease of infrared absorption takes place are observed; one from 70 to 130°C and the second from 270 to 500°C. Results obtained from isothermal annealing show that lattice defects resulting from atomic displacements can be completely removed by a vacuum anneal at 450°C for more than 14 hours. The results also indicate that the effects of displaced atoms on infrared absorption are greater than that of the transmutation-produced impurities. From these observations, the effective introduction rate of displaced atoms was estimated to be 0.015 displaced atoms per incident neutron with the assumption that two acceptors are produced for each displaced atom. This value is much smaller than the one theoretically calculated. Further analysis of the experimental results leads to the conclusion that the disagreement between observed and calculated results is likely due to the annealing of a majority of displaced atoms during the course of irradiation and that the survivals are mainly produced by the recoil effects resulting from (n,γ) reaction. Such displaced atoms are stable at room temperature for a relatively long period. (auth)

58344 (LA–4693) QUARTERLY STATUS REPORT ON THE ADVANCED PLUTONIUM FUELS PROGRAM, JANUARY 1–

MARCH 31, 1971. (Los Alamos Scientific Lab., N. Mex.). May 1971. Contract W-7405-eng-36. 27p. Dep. NTIS.

Activities in programs directed toward evaluation of neutron irradiation effects on LMFBR fuels are summarized. Progress is reported on equipment development, hot cell design modifications, methods for analytical measurements of U and Pu, irradiation testing of fuels, B_4C structural studies, and development of analytical standards for fast breeder oxide fuels. (J.R.D.)

Corrosion and Erosion

58345 INVESTIGATION OF THE VOLATILIZATION OF MgO AND ZrO_2 IN OXIDIZING ATMOSPHERES. Karaulov, A. G.; Eltysheva, A. A.; Mayauskas, Yu. S.; Yanulis, V. V.; Grinyute, G. A. (Refractories Research Inst., Kiev. Inst. of Physico-technical Problems of Power Engineering, Vilnyus, USSR). Refractories (USSR) (Engl. Transl.); 12: No. 1-2, 121-4(Jan-Feb 1971).

Translated from Ogneupory; 12: No. 2, 49-53(Feb 1971).

The rates of volatilization of refractories made from magnesia and zirconia stabilized with CaO in an oxidizing atmosphere (in air) up to 1900°C are similar; above 2000°C the volatilization rate of magnesia sharply increases; and at 2200°C its magnitude is an order greater than in the specimens of zirconia. The volatilization rate of zirconium dioxide in an oxidizing atmosphere at the temperature of intensive volatilization (2300°C) is about the same as in an inert atmosphere. (auth)

Preparation and Fabrication

58346 (CONF-711002--, pp 144-6) SIMPLE TECHNIQUE OF PRODUCING THIN CARBON FILMS. Maier-Komor, P. (Technische Universitaet, Munich (West Germany)). Oct 1971.

From third international symposium on research materials for nuclear measurements; Gatlinburg, Tenn. (5 Oct 1971).

A method of preparing thin carbon films by evaporation is described. The process involves electrically evaporating a carbon rod at low pressure. A release agent is used composed of betaine monohydrate and D^+ sacharose. Carbon films in the range 3 $\mu g/cm^2$ to 250 $\mu g/cm^2$ can be produced. (J.R.D.)

58347 (JUL--730-RW) INVESTIGATION AND PREPARATION OF SPHERICAL DOPED UO_2 FUEL PARTICLES. A Report on the Clarification of the Retarding Power of Coated Particles for Solid Fission Products. Hamesch, Muwaffak (Kernforschungsanlage, Juelich (West Germany). Institut fuer Reaktorwerkstoffe). Feb 1971. 119p. (In German). Dep. NTIS (U. S. Sales Only).

The suitability of known sol-gel methods for the introduction of solid fission products into UO_2 cores and the fission product retention capacity of bare and pyrocarbon-coated particles were studied. In the study of the sol-gel methods it was determined that the fission products Y, Zr, Nb, some rare earths, Al, and Mg were incorporated in amounts from 1 to 10 at. % into the spherical UO_2. The fission products Sr and Ba were simulated in amounts of the 0.8 to 2 at. %, which corresponds to a burn-up of 10%. The essential step in the introduction of Ba and Sr was the addition in the form of their nitrated to the washed $UO_2 \cdot nH_2O$ before peptization. A more accurate study showed that at sufficiently low pH values of the sol not Sr^{2+} or Ba^{2+} ions were washed from the gel particles during the washing with ammonia. The model particle obtained was characterized by chemical and γ spectrometric analysis with the help of metallographic and microprobe analysis and by measurement of the lattice constants. The dependence of the fission product release on the type of gas, the crucible material, the sintering method, the particle porosity, the particle composition, and the compatibility of the model particle with the crucible material. In the study of the dependence of the fission product release on the particle composition, temperature, and annealing time it was shown that the fission products Ba and Sr were released from the doped particle proportionally to the annealing duration and temperature. The particles which contain Nb or Al in addition to the fission products Ba or Sr show lower fission product loss in comparison with the particles without oxide additions. This model particle was coated with pyrocarbon by propene pyrolysis and an extended annealing of 500 hr at 1000, 1200, and 1550°C was investigated. The results showed that the fission product release of the model particle doped only with Ba or Sr increases with increasing annealing temperature. The coated particle which had an Al_2O_3 or Nb_2O_5 addition showed no fission product loss. By oxide additions such as Al_2O_3 or Nb_2O_5 to the UO_2 fuel particle an improvement of the retention capacity of the particle for Sr and Ba can be obtained. (tr-auth)

58348 (LFEN-NI--53-a) TECHNIQUES FOR PREPARATION OF UO_2--NIOBIUM (OR MOLYBDENUM) CERMETS. da Silva, C. Pacheco; Carvalhinhos, H.; Sampaio, A. Oliveira (Junta de Energia Nuclear, Sacavem (Portugal). Laboratorio de Fisica e Engenharia Nucleares). 1969. 33p. (In Portuguese). Dep. NTIS (U. S. Sales Only).

A bibliographic study was made of the techniques for the preparation of UO_2 cermets with Nb or Mo as the base metal and at UO_2 concentrations of at least 80% by volume. On the basis of the information gathered, a technique was selected which led to final products of high density and homogeneous structure. (tr-auth)

58349 (ORNL--4713) DEVELOPMENT OF MANUFACTURING PROCEDURES FOR HFIR FUEL PLATES TO ORNL SPECIFICATION. Knight, R. W.; Sherman, F. L. (Oak Ridge National Lab., Tenn.). Sep 1971. Contract W-7405-eng-26. 48p. Dep. NTIS.

Techniques for manufacture of High Flux Isotope Reactor (HFIR) fuel plates were originally developed at the Oak Ridge National Laboratory (ORNL). Since ORNL is not a manufacturing facility and many techniques had to be worked out to improve the efficiency of manufacture of precision parts at a high production rate, a great deal of the work had to be left to the contractor, Texas Instruments Inc. The development of these production procedures based on the ORNL original fabrication concept is described. Aspects of production such as fuel plate blisters, fuel core outlines, homogeneity measurements, and material are discussed. (auth)

58350 (RD/B/N--2020) METHOD FOR PRODUCING THIN FOILS FROM GRAPHITIC MATERIALS FOR TRANSMISSION ELECTRON MICROSCOPY. Baker, C. (Central Electricity Generating Board, Berkeley (England). Berkeley Nuclear Labs.). Jun 1971. 7p. Dep. NTIS (U. S. Sales Only).

It is shown how thin foils of a number of graphitic materials can be produced using ion beam thinning. The advantages of the method are that good foils can be made from graphites with a two phase binder/particle structure and also from pyrolytic graphites. In the latter case foils can be produced from any orientation. (auth)

58351 (RT/ING--(70)30) ACTIVITY AND INFRASTRUCTURE OF CNEN FOR THE REUSE OF PLUTONIUM FOR NUCLEAR FUEL. (Comitato Nazionale per l'Energia Nucleare, Rome (Italy)). [nd]. 157p. (In Italian). Dep. NTIS (U. S. Sales Only).

The work done to give Italy a capacity for the production of nuclear fuels containing Pu is summarized. The experience at the Mol Pu laboratory in the training of technicians is reported. The production of microspheres of $(U,Pu)O_2$ by the SNAM and the CNEN methods is described. The preparation of fuel irradiation samples is also described. The Pu laboratory at Casaccia is described in detail with emphasis on the systems for the prevention and control of nuclear and nonnuclear incidents. Procedures used for the fabrication of fuel elements containing Pu are described. A series of tests in the materials testing reactor on Pu fuels is described. (J.S.R.)

58352 (Y-DA-2123(Rev.1)) PYROLYTIC CARBON INFILTRATION STUDIES. Taylor, A. J.; Paluzelle, R. (Union Carbide Corp., Oak Ridge, Tenn. Y-12 Plant). 8 Sep 1971. Contract W-7405-eng-26. 120p. Dep. NTIS.

Work done to produce and investigate both the conditions for successful infiltration and the characteristics of the deposited pyrocarbon is summarized. With the interest in pyC-infiltrated materials being related to inherently good ablation characteristics and, consequently, reentry vehicles, the scope of the work included an evaluation of techniques for joining felt to form structures of closed geometry or, preferably, generating the means for obtaining or fabricating these structures without seams. (auth)

58353 ATTACK POLISHING OF METALS AND CERAMICS. Ambler, J. F. R. (Atomic Energy of Canada Ltd., Chalk River, Ont.). pp 1-6 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

Attack polishing methods, in which the chemical reaction product is insoluble, can produce surfaces that are essentially flat and free from mechanical deformation. UO_2, U_3Si, and Zr alloys were used to show that these are important features for some applications. Attack polishing is not the ultimate polishing method for all ma-

XUM

terials or for all applications. However, it is a useful additional metallographic technique that helps reveal the maximum amount of reliable information from specimens. (P.C.H.)

58354 CHEMICAL ETCHANT FOR $(PuTh)O_2$ CERAMIC MICROSCOPY. Baker, C.; Johnson, K. A. (Los Alamos Scientific Lab., N. Mex.). pp 7-8 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

A method is described for the preparation and etching of $(PuTh)O_2$ sintered ceramics and cermets for optical microscopy. The materials were epoxy mounted and ground in three stages: 100, 320, and 600 grit. They were polished on vibratory polishers in two stages. The samples were then chemically treated with fresh solutions of 10 ml HI, 10 ml HCl, 4 drops HNO_3, and 4 drops HF. The etching solution is applied as a miniscus over the polished surface and the etching time is controlled by inspection. It was found convenient to etch for five minutes, rinse, and ultrasonically clean, and then examine the etch with a microscope. (P.C.H.)

58355 MANUFACTURING METHOD FOR NUCLEAR FUEL. (to Belgonucleaire). British Patent 1,229,388. 21 Apr 1971. Priority date 17 Apr 1969, Belgium.

An improved process for manufacturing fuel material for nuclear reactors, particularly gas-cooled reactors, is described. The nuclear fuel element produced consists of a graphite container at least partially filled with fuel particles substantially homogeneously dispersed in a consolidation paste. The particles and the paste are introduced into the container which is subjected to centrifugation about an axis differing from the axis of the container whereby the particles and paste are intimately dispersed. (L.C.L.)

58356 ELECTRO-EROSION RESISTANCE OF REFRACTORY CARBIDES WITHIN CORRESPONDING RANGES OF HOMOGENEITY. Lemeshko, A. M.; Naumenko, V. Ya.; Upadkhaya, G. Sh. Elektron. Obrab. Mater.; No. 4, 6-8(1970). (In Russian).

The resistance of refractory carbides (TaC, NbC, HfC, etc.) to electroerosion machining was studied as a function of C content within the corresponding ranges of homogeneity. The electroerosion resistance increased with increasing atomic number of the metal, and fell with increasing C content, except that in the case of TaC and NbC there was a maximum at the composition $MeC_{0.85}$. These effects were attributed to the influence of the stable sp^3 electron configurations of the C atoms and the d^5 configurations of the metal atoms. (Metals Abstr.)

58357 MAKING HEATING ELEMENTS ON THE BASIS OF ZIRCONIUM DIOXIDE FOR HIGH-TEMPERATURE FURNACES. Rutman, D. S.; Taksis, G. A.; Toropov, Yu. S.; Maurin, A. F. Refractories (USSR) (Engl. Transl.); 12: No. 1-2, 42-7(Jan-Feb 1971).

Translated from Ogneupory; 12: No. 1, 36-41(Jan 1971).

A technology was developed and resistor elements designed on the basis of zirconium dioxide for operation in air at up to 2100°C. A design was also developed for test rigs which include a furnace for individual testing of the heating elements and a furnace with three zirconia elements. An electric operating circuit with automatic control with respect to the working current of the heating elements was also developed. The results of tests show that in the working region of the furnace with three zirconia elements it is possible to carry out heating in an air atmosphere up to 1950°C, with a surface temperature on the high-temperature part of the heating elements of 2050 to 2100°C. One of the essential conditions for operating such furnaces is individual current regulation of each element. The furnace can be operated in laboratory testing using the heating elements singly, maintaining them at the maximum temperature for a period of several tenths of an hour. (auth)

58358 EFFECT OF SYNTHESIS TEMPERATURE ON THE SINTERING OF BORON NITRIDE. Repenko, K. N.; Getman, I. A. (Scientific-Research Inst. of Refractories, Kiev). Refractories (USSR) (Engl. Transl.); 12: No. 1-2, 110-15(Jan-Feb 1971).

Translated from Ogneupory; 12: No. 2, 37-43(Feb 1971).

Results of investigations are presented to show that the temperature used to obtain boron nitride has important effects on physical properties such as shape, crystal sizes, and crystal structure perfection on which the properties of the finished products depend. For the production of articles made by firing the raw materials in nitrogen, or hot pressing, it is necessary to use powdered boron nitride synthesized at 950°C, having a surface area of more than 40 m^2/g, and a defect crystal structure. (auth)

58359 EFFECT OF THE CRYSTAL STRUCTURE DISORDER OF BN ON ITS SINTERING. Poluboyarinov, D. N.; Kuznetsova, I. G.; Sadovskii, E. P.; Balashov, V. A. (Inst. of Chemical Technology, Moscow). Refractories (USSR) (Engl. Transl.); 12: No. 1-2, 99-104(Jan-Feb 1971).

Translated from Ogneupory; 12: No. 2, 27-32(Feb 1971).

The effects of crystal structure disorder in BN during sintering (under load and without load) were established. During hot pressing to achieve high density and strengths, only the powdered BN that has appreciable crystal structural distortions and high dispersion will sinter. After the hot pressing of these materials (mesographitic and turbostratic), and also after ordinary sintering, the BN has a graphitic structure. Results of investigations show that in production of sintered BN ceramics, by hot pressing and ordinary sintering, the synthesis of active BN powders having a disordered crystal structure and a high dispersion is feasible. (auth)

58360 CURRENT EFFICIENCY IN ALUMINA ELECTROLYSIS. II. DETERMINATION OF CURRENT EFFICIENCY. Botor, Jan. Rudy Metale Niezelaz.; 15: No. 8, 433-6(Aug 1970). (In Polish).

Four main methods for the determination of current efficiency are described: anodic gas analysis, statistical, radioisotope, and dissolution of non-active elements. The last method, based on neutron activation analysis in conjunction with γ spectrometry and utilizing small additions of metallic ^{110m}Ag radioisotope (half life 270 days) in the bath, is considered to be potentially the most promising. (Metals Abstr.)

58361 SILICON CARBIDE AS A REINFORCEMENT. Parratt, N. J. Composites; 1: No. 3, 141-4(Mar 1970).

Silicon carbide whisker crystals grown by vapor-phase transport techniques have very high strength and improved density as compared with fibers grown on W; they are also very economical. The as-grown whiskers must be dispersed into a slurry for cleaning in a hydrocyclone, then graded by screening and aligned by extrusion to orient them for maximum volume loadings. Light alloys are a particularly attractive matrix for these fibers, but much more developmental work is needed. Rapid forming of composites from Al alloys with short SiC whiskers has been particularly successful. The longest grades of SiC whiskers give good reinforcement in plastics. (Metals Abstr.)

58362 MANUFACTURING OF FUEL PELLETS WITH CENTER HOLES. Dippel, Th.; Guenther, E. (Kernforschungszentrum, Karlsruhe, Ger.). Atomwirt., Atomtech.; 16: No. 8-9, 431-2(Aug-Sep 1971). (In German).

Preparation of oxide fuel pellets with axial holes is possible if the holes are formed in non-sintered pellets. With the exception of minor technical equipment, the method requires only reliably pressed material. With respect to sintering, no special behavior is observed. Variations of density, length, and diameter are indistinguishable from that of normal cylindrical pellets. Refinement of the final products by additional shaping is possible. (tr-auth)

58363 FORMING PROCESSES FOR METAL MATRIX COMPOSITES. Cooper, G. Composites; 1: No. 3, 153-9(Mar 1970).

Metals as matrices appear potentially superior to polymers and ceramics because of their high strength and stiffness, insensitivity to temperature extremes and capacity for plastic deformation. Disadvantages are that metal-to-fiber bonds are poor when low-temperature fabrication is employed and that oxidation between fiber and matrix occurs when processing is at high temperature. Methods most commonly used for preparing metal/matrix composites include: liquid-metal infiltration, in which a molten metal such as Al is cast around fibers of nitrided B; vapor deposition, as in the deposition of Al on C fibers by the thermal decomposition of tri-isobutyl Al; electroforming, as in composites of C fibers coated with Ni, and the related process of plasma spraying in which Al is deposited on B fibers wound on an Al foil-covered drum; mechanical compaction in which wires of steel, B or silicon carbide are pressed into soft metals such as Al; and unidirectional solidification, a process in which melts of eutectic alloys such as those involving Ni, Al, and Nb solidify slowly under a thermal gradient to produce parallel rods of one phase dispersed in the other. (Metals Abstr.)

58364 VIBRATORY COMPACTION OF URANIUM DIOXIDE. II. COMPACTION OF SOL-GEL UO_2 POWDER WITH A PNEUMATIC VIBRATOR. Naruki, Kaoru (Power Reactor and Nuclear Fuel Development Corp., Tokai, Japan). J. Nucl. Sci. Technol. (Tokyo); 8: No. 9, 520-7(Sep 1971).

Vibratory compaction was studied making use of a pneumatic vibrator to pack sol-gel UO_2 powder in a thermal reactor type fuel canning tube. It is shown that the pneumatic vibrator utilized is superior to the commonly used electrodynamic vibrator from the viewpoint of easy operation and high attainable density. Compared with the latter type, the pneumatic vibrator is less restrictive in the range of mesh size composing each fraction of the starting powder, and good results could be obtained with a powder with coarse, medium, and fine fractions respectively having mesh ranges of 4 ~ 6 (60%), 20 ~ 65 (20%) and −200 (20%). The selected operational conditions are: vibration frequency 300 cpm, driving air pressure 3 kg/cm^2, and duration of operation 10 min. Fuel rods of 100 cm length compacted in these conditions with sol-gel UO_2 (particle density: 96% theoretical density T.D.) attained a bulk density of 88.2 ± 0.2% T.D. with an axial density distribution as uniform as ±3% T.D. 58365 (AI-AEC-12983) PREPARATION OF TUNGSTEN-MODIFIED MIXED CARBIDE. Ervin, Guy Jr.; Carroll, J. W. (Atomics International, Canoga Park, Calif.). [Mar 1970]. Contract AT(04-3)-824. 14p. Dep. NTIS.

After a survey of available methods of synthesis and fabrication of tungsten-modified mixed carbide, two methods were investigated in the laboratory, one of which is considered to be suitable for preparation of fuel for a swelling test. Sintering a mixture of (U,Pu)C and tungsten powders failed to dissolve a major part of the tungsten. The successful method was carbothermic reduction of a mixture of the oxides, UO_2, PuO_2, and WO_3, which yielded solid solutions of tungsten in single phase uranium plutonium monocarbide. (auth)

58366 (CEA-CONF-1820) DEVELOPMENT OF PROPERTIES OF NUCLEAR GRAPHITE OBTAINED BY A MIXTURE OF COKES. Cornuault, P.; Lore, J. (Compagnie Pechiney, Paris (France)); Rappeneau, J.; Yvars, M.; Mottet, P. (Commissariat a l'Energie Atomique, Saclay (France). Centre d'Etudes Nucleaires). [1970]. 28p. (In French). Dep. NTIS (U. S. Sales Only).

A series of molded pitch bonded graphites having as filler materials various proportions of mixtures of two different cokes was studied. One of these cokes is isotropic, the other is a fibrous conventional coke. The physical, mechanical, and thermal characteristics were studied for each product. The measured properties usually conform with the mixtures law. Dimensional variations caused by neutron irradiation were determined by a bromation method. These properties also also conform with the mixtures law. By mixing different cokes, nuclear graphites can be obtained having desired properties. It is possible to modify the graphite grade fluctuations associated with raw materials. (auth)

58367 (EUR-4327) RELEASE OF GASEOUS FISSION PRODUCTS FROM CARBONS. Barth, F. (European Atomic Energy Community. Brown Boveri/Krupp Reaktorbau GmbH, Mannheim (West Germany). Kernforschungsanlage, Juelich (West Germany)). 1969. 214p. (In German). NTIS (U. S. Sales Only).

Graphite is used both as moderator and a cladding or filler material in the development of fuel elements for high temperature gas-cooled reactors, because of its good heat resistance. However, the structural composition of graphite gives rise to certain problems relating to the release of fission products from the elements. This applies chiefly to cases in which the actual nuclear fuel is in the form of UO_2 or UC_2 embedded in a graphite matrix. Fission products expelled from the nuclear fuel by a recoil mechanism are taken up by the graphite, so that their release from the element is determined by the retentive capacity of the graphite. The problem of the release of gaseous fission products from carbon is discussed. The aim of the studies was, therefore, to elucidate the release of gaseous fission products, although in the meantime interest shifted to the problem of the release of nonvolatile fission products from carbon. (auth)

58368 ELECTRIC CONDUCTIVITY OF SOLID SOLUTIONS OF $(ThO_2)_{0\ 75} - (CeO_2)_{0\ 25}$ AT HIGH TEMPERATURE. Hammou, A.; Deportes, C.; Robert, G.; Vitter, G. (Domaine Univ., Saint-Martin d'Heres, France). Mater. Res. Bull.; 6: No. 9, 823-32 (Sep 1971). (In French).

The electric conductivity of the solid solution $(ThO_2)_{0.75}$–$(CeO_2)_{0.25}$ is studied as a function of temperature (1000 to 1500°C) and oxygen partial pressure (1 to 10^{-20} atm). The transport number measurements indicate a preponderant electronic conductivity. Both conductivity and resistance to chemical corrosion of this compound are compared with several conductive ceramics; the latter appear a promising material for "hot electrodes" in MHD generators. (auth)

58369 CRYSTAL GROWTH OF V_nO_{2n-1} ($3 \le n \le 8$) BY THE CHEMICAL TRANSPORT REACTION AND ELECTRICAL PROPERTIES. Nagasawa, Noichi (Kyto Univ.). Mater. Res. Bull.; 6: No. 9, 853-63(Sep 1971).

Single crystals of the intermediate vanadium oxides between V_2O_3 and VO_2 with the general formula V_nO_{2n-1} ($3 \le n \le 8$) were grown by the chemical transport reaction using $TeCl_4$ as a transport agent. The reactions were carried out in sealed tubes with the temperature gradient between 1050 and 950°C. The sizes of crystals produced were about 1 ~ 10 mm. The electrical properties of the crystals are summarized. (auth)

58370 DIFFUSION OF OXYGEN IN ZIRCONIA AS A FUNCTION OF OXYGEN PRESSURE. Keneshea, F. J. (Stanford Research Inst., Menlo Park, Calif.); Douglass, D. L. Oxidation Metals; 3: No. 1, 1-14(Jan 1971).

Diffusion of oxygen in monoclinic zirconia was studied using the oxygen-18 gas–solid exchange technique. The zirconia was in the form of spheres prepared by dropping the powdered material through a high temperature plasma. Diffusion was measured as a function of equivalent oxygen pressure, using oxygen and $CO-CO_2$ mixtures, over the range 1 to 10^{-21} atm. In pure oxygen at 700 torr and between 600 and 1000°C, the diffusion is described by the equation, $D^* = 2.34 \times 10^{-2} \exp - (45{,}300 \pm 1200)/RT$. Experiments in $CO-CO_2$ mixtures at 850°C gave self-diffusion coefficients that showed a slight decrease with a decrease in p_{O_2} from 1 to 10^{-6} atm, then a constant value of D^* from 10^{-6} atm, and finally a decrease in D^* from 10^{-19} to 10^{-21} atm. The behavior of D^* with p_{O_2} appears to be in agreement with a defect model involving anti-Frenkel imperfections, i.e., oxygen interstitials and anion vacancies, if it is assumed that the mobility for oxygen interstitials is greater than that for oxygen vacancies. (auth)

58371 STORAGE BEHAVIOR OF SINTERED URANIUM OXIDES. Constantinescu, F.; Prodan, A.; Toacsan, M. (Institut de Physique Atomique, Bucarest). Rev. Roum. Phys.; 16: No. 5, 583-5(1971). (In French).

Calculations were made on the O/U ratio for stored sintered uranium oxides with different specific surfaces. The results showed that the rate of increase in the O/U ratio is proportional to the specific surface. Experimental studies were made on the specific surface order to determine if the differences between the calculated data and the experimental data are not due to a modification in grains, with time, under the influence of air. The results showed a decrease in the value of the specific surface with time; the uranium oxide powders undergo some transformations during storage besides that concerned with the O/U ratio and the grain texture. The modifications made evident by the variation in the values for specific surface entail also the modification of the behavior of the sintered powders. (P.C.H.)

58372 QUANTUM MECHANICAL CALCULATIONS OF EMPIRICAL POTENTIALS BY PERTURBATION METHOD AND OXYGEN DIFFUSIVITY IN POLYCRYSTALLINE Pr_7O_{12}. Fox, Donald Lee. Tucson, Ariz.; Arizona State Univ. (1971). 158p. University Microfilms Order No. 71-18,961.

Thesis.

Part I involves the development and application of a perturbation method designed to investigate empirical potentials of a diatomic molecule having a form similar to the Morse potential. By making small corrections on the Morse potential, the effects of these corrections can be investigated with the perturbation theory. Each of these potentials consists of two parts, i.e., the Morse potential and a correction term. By using perturbation theory, the corrected potential energies and wave functions are obtained. As an application, four generalized Morse potentials are studied. The performance of these four potentials is evaluated against other empirical potentials as to their ability to predict spectroscopic constants and reproduce the experimental curves. The four potentials were found better than average at predicting spectroscopic constants, but poor at reproducing the potential energy. Franck–Condon factors are also calculated from corrected wave functions. The usefulness of this perturbation method lies in the fact that it gives analytical expressions for both eigenvalues and eigenfunctions. In Part II, the oxygen self-diffusion coefficient was measured in polycrystalline $PrO_{1.714 \pm \delta}$ by a method of heterogeneous isotope exchange. The studies were made at various temperatures and pressures. The dependence of the diffusion coefficient with pressure at a given temperature shows curvature with the slope decreasing with increasing temperature. Various mechanisms for mass transport are discussed to rationalize the experimental behavior. Information about the structure and conductivity is used to propose a complex mechanism involving competing defects. Similar

XUM

mechanisms proposed in other systems are discussed in their relation to PrO_x. A mechanism involving charged and uncharged oxygen interstitials is proposed to explain the curvature and change in pressure dependences. At high temperature and low pressures, it is suggested that oxygen vacancies become significant. (Diss. Abstr. Int., B)

58373 KINETICS OF HYDROGEN ENGASSING OF DELTA-ZIRCONIUM HYDRIDE. Paetz, Peter; Luecke, Kurt (Interatom, Bensberg, Ger. Technische Hochschule, Aachen). Z. Metallk.; 62: No. 9, 657-62(Sep 1971). (In German).

The kinetics of hydrogen engassing of δ zirconium hydride was measured in the temperature range from 650 to 800°C. The hydrogen absorption by zirconium hydride follows a parabolic time law and the rate constant k is proportional to the concentration difference and to the square root of the diffusion constant. The temperature dependence of diffusion is given by $D = 0.25 \exp [(-17.8 \times 0.2)/RT]$. The activation energy indicates an indirect site exchange mechanism of the hydrogen atoms from tetrahedral to octahedral interstices. (auth)

58374 EFFECT OF OXYGEN PRESSURE ON THE REDOX POTENTIAL OF MOLTEN MOLYBDENUM TRIOXIDE. Rahmel. A. (Dechema-Inst., Frankfurt am Main). Z. Phys. Chem. (Frankfurt); 74: No. 3-6, 206-15(May 1971). (In German).

The effects of oxygen pressure and low-valence molybdenum oxides on the redox potential of a MoO_3 melt were measured at 850°C. An oxygen electrode with ZrO_2 as the solid electrolyte was used as the reference electrode. The results of the measurements allow the conclusion that the equilibrium $MoO_3 = MoO_{2.5} + \frac{1}{4} O_2$ is established between melt and gas atmosphere. The estimated value of the equilibrium constant is $K \approx 2.3 \times 10^{-3}$ at^{¼}. It may be assumed that the MoO_3 melt has partial electronic conductivity increasing as the oxygen pressure decreases. (auth)

58375 PROPERTIES OF CERAMIC COATINGS OF PHOSPHATE CERAMICS. Verenkova, E. M.; Trofimov, M. G.; Frolov, A. S.; Dikaya, K. I. (All-Union Scientific-Research Inst. of Aviation Materials, Moscow). Refractories (USSR) (Engl. Transl.); 12: No. 1-2, 48-52(Jan-Feb 1971).

Translated from Ogneupory; 12: No. 1, 41-5(Jan 1971).

The phosphate ceramic coatings made from Al_2O_3 and from ZrO_2 containing ortho- and metaphosphate of aluminum, in terms of properties such as adhesion, thermal-shock resistance, and impact strength are better than other coatings based on Al_2O_3 and ZrO_2. The low thermal conductivity, the appreciable bonding strength with metals and alloys, and the high thermal-shock resistance are the basis for recommending the coatings for protecting metals and alloys exposed to the action of high-temperature gas currents. (auth)

58376 STATISTICAL METHODS OF DETERMINING THE THERMAL-SHOCK RESISTANCE OF REFRACTORIES. Dauknis, V. I.; Peras, A. Ya.; Prantskyavichyus, G. A.; Yurenas, V. L. (Inst. of Physicotechnical Problems of Power Engineering, Vilnyus, USSR). Refractories (USSR) (Engl. Transl.); 12: No. 1-2, 125-8(Jan-Feb 1971).

Translated from Ogneupory; 12: No. 2, 53-6(Feb 1971).

A statistical analysis of the test results for the thermal-shock resistance of a large batch of specimens of zirconium dioxide established that there is satisfactory correspondence between the experimental data and the exponential distribution of Weibull. The appreciable spread in the thermal-shock resistance criteria R for brittle refractory materials should be considered as regular, and therefore to obtain reliable calculation characteristics for thermal-shock resistance it is necessary to treat the test results statistically. It is proposed that one of the causes of variation in the thermal-shock resistance criterion R is the slight (unavoidable even within the limits of a single batch of specimens) change in the density of the material. (auth)

58377 MASS SPECTRUM OF ZIRCONIUM BOROHYDRIDE. Khodeev, Yu. S.; Kirin, B. M. (Inst. of High Temperatures, Moscow). Zh. Strukt. Khim.; 12: No. 3, 531-2(May-Jun 1971). (In Russian).

The mass spectrum of $Zr(BH_4)_4$ exhibited a large quantity of lines, attributed to the presence of five Zr isotopes, two B isotopes, and possibly ionized H atoms. A contrast between this spectrum and that of $Be(BH_4)_2$ is discussed. (K.S.W.)

58378 HELIUM ESCAPE FROM IRRADIATED BORATED MATERIALS WITH CARBON–GRAPHITE MATRIX. Emel'yanov, I. Ya.; Grebennikov, R. V.; Moiseev, D. N.; (and others). At. Energ. (USSR); 31: No. 3, 215-18(Sep 1971). (In Russian).

The results of temperature dependence studies of helium escape from irradiated borated samples with a carbon-graphite matrix are presented. Tests were conducted in a highly sensitive facility developed on the basis of the reconstructed PTI-6-type leak detector. The procedure used made it possible to determine the activation energy of helium escaping from irradiated materials when heated as a function of properties and dimensions of boride phase particles and matrix structure. At low temperatures (200 to 300°C), an increase in helium escape was observed for irradiated samples having finer boride phase and porous carbon–graphite matrix. (auth)

58379 IONIC TRANSPORT NUMBERS OF GROUP IIa OXIDES UNDER LOW OXYGEN POTENTIALS. Alcock, C. B.; Stavropoulos, G. P. (Univ. of Toronto). J. Amer. Ceram. Soc.; 54: No. 9, 436-43(Sep 1971).

The ionic transport numbers of BeO, MgO, CaO, and SrO in single-crystal and polycrystalline samples were examined under low oxygen potentials between 900 and 1180°C. The oxygen potentials were fixed by using metal/metal-oxide electrodes in electrochemical cells with the samples of the alkaline earth oxides as solid electrolytes. The electromotive forces of these cells were compared with the emf values obtained from similar cells of high stability using high-purity thoria-based electrolytes. From the results it could be concluded that under comparable conditions of low oxygen pressure the electron transport number increases with increasing ionic radius of the group II element. Only BeO and MgO approach electrolytic behavior, and this occurs at relatively high oxygen pressures ($>10^{-10}$ atm). (auth)

58380 DYNAMIC BEHAVIOR OF DISPERSED INHOMOGENEOUS SYSTEMS. Leiber, C. O. Planseeber. Pulvermet.; 19: No. 1, 25-36(Mar 1971). (In German).

For the case of discontinuities present in a matrix which are small relative to the impact rise length and which behave as first-order acoustic oscillators, it is shown that the application of a dynamic load results in behavior radically different from that of homogeneous materials when the discontinuities carry out a mass-controlled motion. The range of onset of this motion depends on the density ratio, the diameter of the discontinuity, the viscosity and shear modulus G" of the matrix, and the impact gradient in the matrix. Consequently, there occurs in the mass-controlled range of motion, additionally to the hydrodynamic pressure, pressure oscillations superposed on the former, which determine the strength of the overall system. For the case of WC–Co cemented carbide, the effect of various defects (discontinuities) in dynamical load situations is analyzed. (auth)

58381 RESIDUAL STRESSES IN CERMETS. Bol'shakov, P. P.; Lanin, A. G.; Portnov, V. F. Tr. Leningrad. Politekh. Inst.; No. 305, 22-8(1970). (In Russian).

Using an x-ray method, with precision of ±20 MN/m^2 (2 kg/mm^2), determinations were made of residual stresses in specimens of the 85% ZrC + 15% Zr cermet. The method was used to study the behavior of specimens subjected to cyclic temperature changes. The upper temperatures were 1500, 1800, and 1950°C and the lower temperature 250°C in each case. The rates of heating and cooling were 250 and 25°C/sec, respectively. (Referativnyi Zh.)

58382 SURFACE CHANGES IN CARBON FIBERS DURING GRAPHITIZATION. Donnet, J. B.; Dauksch, Helmuth (CNRS, Mulhouse, France). J. Microscop.; 10: No. 3, 337-40(Apr 1971). (In French).

AC type carbon fibers were heated to 2500°C and converted into AG type graphite fibers by graphitization. Young's modulus, rupture strength, and the size of the crystallites as determined by x-ray crystallography are given. The shear strength of epoxide resins reinforced with AC or AG fibers was determined. (France)

58383 EFFECT OF A STEADY ELECTRIC FIELD ON THE DIFFUSION OF OXYGEN THROUGH POLYCRYSTALLINE LAYERS OF CARBON OR VANADIUM PENTOXIDE. Kulicki, K.; Skulski, L. (Technical Military Academy, Warsaw). Bull. Acad. Pol. Sci., Ser. Sci., Math. Astron. Phys.; 19: No. 6, 551-6(1971).

Studies were performed on a directed oxygen diffusion through thin polycrystalline layers made of carbon or V_2O_5 (separating, at the beginning of experiments, two chambers filled with pure oxygen and argon, respectively) under the influence of a constant electric potential difference applied perpendicularly to the layers. It is shown that there is an apparent dependence between the amount of oxygen diffusing through the layers and the direction of the applied steady electric field. The oxygen diffusion was markedly faster when the negatively charged electrode was on the side of the oxygen-filled chamber, whereas the positively-charged electrode was then in the chamber filled with argon, which was subsequently analyzed for the content of oxygen. (auth)

58384 STUDIES OF VIBRATION SPECTRA OF BONDED HYDROGEN ATOMS USING A PULSED NEUTRON SOURCE.

Day, D. H.; Sinclair, R. N. (Atomic Energy Research Establishment, Harwell, Eng.). J. Chem. Phys.; 55: No. 6, 2807-11 (15 Sep 1971).

The vibration spectra of some hydrogeneous compounds have been studied over the range 300 to 4000 cm^{-1} by observing incoherent neutron scattering. The paper describes the use of a crystal analyzer technique with a pulsed neutron source based on the Harwell 45-MeV electron linac. Time-of-flight spectra of neutrons downscattered to a final energy, fixed by the crystal spectrometer, were measured. Data for ZrH_2, H_2O, $NaNH_2$, and $C_6H_5NH_2$ are reported and compared with available results from optical spectroscopy and, in the first two cases, other neutron-scattering data. (auth)

58385 THERMAL CONDUCTIVITY OF CERAMICS BASED ON BORON NITRIDE AND ALUMINUM NITRIDE. Duderov, Yu. G.; Kiryutin, A. K. (Moscow Engineering-Physics Inst.). Refractories (USSR) (Engl. Transl.); No. 9-10, 587-8(Sep-Oct 1970).

Translated from Ogneupory; No. 9, 54-5(Sep 1970).

Results of experimental work on the thermal conductivity of ceramics composed of 50% AlN + 50% BN are reported. Material preparation is described and resulting data obtained at 1000 to 1600°C are presented graphically. (J.R.D.)

58386 COMPARISON OF TWO METHODS FOR TESTING THE ABRASIVE RESISTANCE OF REFRACTORIES. Kamenetskii, A. B.; Gladkaya, N. V. Refractories (USSR) (Engl. Transl.); No. 9-10, 652-5(Sep-Oct 1970).

Translated from Ogneupory; No. 10, 41-5(Oct 1970).

Results of abrasion tests on refractories using gas borne fused corundum particles are compared with tests on similar materials using a cutting wheel tipped with diamonds. It was found that the abrasion test methods are comparable and that wear resistance depends on crystal hardness and matrix bond strength. (J.R.D.)

Structure and Phase Studies

58387 (ANL-7823) CHEMICAL ENGINEERING DIVISION PHYSICAL CHEMISTRY OF LIQUID METALS AND MOLTEN SALTS SEMIANNUAL REPORT, JANUARY–JUNE 1971. Cairns, E. J.; Cafasso, F. A.; Cunningham, P. T.; Eberhart, J. G.; Feder, H. M.; Maroni, V. A.; Schnyders, H. C.; Veleckis, E.; Tevebaugh, A. D.; Vogel, R. C. (Argonne National Lab., Ill.). Jul 1971. Contract W-31-109-eng-38. 62p. Dep. NTIS.

The thermodynamic and chemical properties of liquid metals and molten salts continue to be of interest. Partial phase diagrams for the lithium-sulfur and lithium-tellurium systems are reported. Pseudo-ternary systems of the type lithium chalcogenide-chalcogen-alkali halide eutectic have been studied by several techniques, including emf measurement, and thermodynamic and phase data are reported. Refinements in a model for calculating the solubility of noble gases in liquid metals have been made. Raman spectroscopy has been used to study the structure of divalent metal halides and polyatomic anions in melts. Preliminary studies of lithium-hydrogen-metal systems of importance to fusion reactors are reported. A study of the homogeneous nucleation of vapor bubbles in superheated liquids has been started. (auth)

58388 (MLM-OP-71006) QUANTITATIVE ANALYSIS OF A CERMET SPHERE. Kelly, M. D.; Selle, J. E. (Mound Lab., Miamisburg, Ohio). [nd]. 14p. (CONF-710902-4). Dep. NTIS.

From fourth annual meeting of the International Metallographic Society; Denver, Colo. (21 Sep 1971).

A ThO_2–molybdenum cermet sphere was fabricated as part of the development effort relating to the Multi-Hundred Watt heat source program. Molybdenum-coated ThO_2 shards were pressed into a 1½ inch diameter sphere using graphite dies. The graphite was removed by machining leaving the composite sphere. The sphere was sectioned through the poles, metallographically polished, and analyzed using the Leitz Classimat to determine pressing characteristics. Density, form factor, particle size, composition, and orientation measurements were taken. Metallographic procedures, as well as the operation of the Classimat and the interpretation of the composite sphere data, are discussed. (auth)

58389 (SRO-552-8) QUANTITATIVE DETERMINATION OF THE STRUCTURE-PROPERTY RELATIONSHIPS IN NUCLEAR FUEL ELEMENT MATERIALS. Quarterly Progress Report, March 15, 1971–June 15, 1971. Rhines, F. N.; DeHoff, R. T.; Whitney, E. D. (Florida Univ., Gainesville. Dept. of Metallurgical and Materials Engineering). Jul 1971. Contract AT-(38-1)-552. 76p. Dep. NTIS.

Results of studies on gas permeability, thermal conductivity, short-time mechanical properties, and creep behavior of Ni and UO_2 powders are reported. Quantitative microscopic data support the hypothesis that both the nickel and UO_2 powders follow paths of microstructural change which are quantitatively very close to that found for a broad range of equiaxed metal powders. The permeability of nickel sinterings to gas flow varies with the amount of porosity along a path which is parallel to that observed for the variation of genus with porosity in earlier work. Differences in permeability for sinterings obtained from three different particle sizes could be accounted for by a scale factor which is proportional to the initial particle size. Initial measurements of permeabilities of UO_2 sinterings were an order of magnitude lower than those measured for nickel sinterings of comparable internal microstructural state. First measurements of the thermal conductivity of porous UO_2 are below values reported for fully dense UO_2, in qualitative agreement with predicted behavior. Continuing measurements of the tensile properties of nickel sinterings are consistent with earlier findings that the short time mechanical properties increase with density, and are insensitive to differences in the scale of the system. Mechanical properties of UO_2 also follow this pattern, although much additional data is required to establish the correlation. (auth)

58390 LIQUIDUS DETERMINATIONS IN THE PSEUDO-TERNARY SUB-SYSTEM $CaO.Nb_2O_5$–$CaO.TiO_2$–SiO_2 OF THE QUARTERNARY SYSTEM CaO–Nb_2O_5–TiO_2–SiO_2. Jongejan, A.; Wilkins, A. L. (Dept. of Energy, Mines, and Resources, Ottawa). J. Less-Common Metals; 25: No. 2, 109-14(Oct 1971).

Liquidus temperatures in the $CaO \cdot Nb_2O_5 - CaO \cdot TiO_2 - SiO_2$ plane of the $CaO - Nb_2O_5 - TiO_2 - SiO_2$ phase tetrahedron have been determined using the customary quench technique as well as hot-stage microscopy. The $CaO \cdot Nb_2O_5$ and $CaO \cdot TiO_2 \cdot SiO_2$ fields have been outlined. They are wedged between the SiO_2 and $CaO \cdot TiO_2$ fields and appear to have a small boundary in common. (auth)

58391 COMMENT ON THE DEFECT STRUCTURE AND THE TRANSPORT PROPERTIES OF Nb_2O_5. Streiff, R.; Poulton, D. J.; Smeltzer, W. W. (McMaster Univ., Hamilton, Ont.). Oxidation Metals; 3: No. 1, 33-9(Jan 1971).

The defect structure of oxygen-deficient $H-Nb_2O_5$ in several phases was interpreted using a model for correlating the results of electric conductivity measurements and oxygen diffusion parameters with the degree of nonstoichiometry. (J.R.D.)

58392 SUBSTRUCTURE OF γ-VANADIUM SUBOXIDE RESULTING FROM LONG RANGE ORDERING OF OXYGEN. Cambini, M. (CCR-EURATOM, Petten, Netherlands); Pellegrini, G.; Amelinckx, S. Mater. Res. Bull.; 6: No. 9, 791-803(Sep. 1971).

The substructure of the oxide formed by the oxidation of vanadium foils in the range $VO_{0.5}$ has been studied by means of electron microscopy, electron diffraction, and x-ray diffraction. A new phase, called the γ-phase, has been characterized and its relation to the previously known β-phase has been established. The substructure of the γ-phase consists of twins and APB's of different type. (auth)

58393 CRYSTÁLLOGRAPHY OF V_nO_{2n-1} ($3 \leq n \leq 8$). Horiuchi, Hiroyuki (Osaka Univ.); Tokonami, Masayasu; Morimoto, Nobuo; (and others). Mater. Res. Bull.; 6: No. 9, 833-43 (Sep 1971).

Single crystals of vanadium oxides, V_nO_{2n-1} ($3 \leq n \leq 8$), which were synthesized by the chemical transport method, have been studied by the x-ray single-crystal method. The lattices (a_n, b_n, and c_n) of the homologous series with $4 \leq n \leq 8$ can be systematically described on the basis of the parent rutile-type lattice (a_r, b_r, and c_r) as follows: $a_n = -a_r + c_r$, $b_n = a_r + b_r + c_r$, and $c_n = \frac{1}{2}(2n-1)(b_r + c_r)$. These relations can be explained on the basis of the "shear" structures of V_nO_{2n-1} described by Andersson and Jahnberg (1963). The crystal of V_3O_5 has been found to belong to the space group $P2_1/n$, but can be related to the homologous series of V_nO_{2n-1} by adopting the lattice with $2a_n$, b_n, and c_n. (auth)

58394 COLLECTIVE RECRYSTALLIZATION IN ZIRCONIUM CARBIDE AFTER SURFACE COLD-HARDENING. Bozhko, S. A. Izv. Akad. Nauk SSSR, Metal.; No. 6, 212-14(Nov-Dec 1970). (In Russian).

The recrystallization of ZrC on annealing at 1600 to 2000°C after hardening the surface by cold working was studied and isotherms of the corresponding grain-growth characteristics were plotted. Starting at 1750 to 1800°C, collective recrystallization developed. The activation energy of this process diminished with increasing number of C vacancies in the ZrC lattice, being commensurable with the activation energy for boundary diffusion. (Metals Abstr.)

58395 STRESS CHANGES IN TANTALUM CARBIDE WITH THE DEFORMATION RATE AND TEMPERATURE (1,200 AND 2,200^{0}C). Martin, J. L.; Lacour-Gayet, Philippe; Costa, Paul (National d'Etudes et de Recherches Aerospatiales, Chatillon, France). Compt. Rend., Ser. C; 272: No. 26, 2127-30(28 Jun 1971). (In French).

Circular bending tests revealed a microdeformation step, still observable at low temperatures (800°C). Two types of laws are proposed to explain the stress variation with the deformation rate and temperature for a plastic deformation $\epsilon_p = 1.2 \times 10^{-3}$; both laws take into account internal stresses which are important at high temperatures, high activation enthalpies (>5 eV) and activation volumes of at least 50 b^3. (France)

58396 PROCEEDINGS OF THE THIRD ANNUAL TECHNICAL MEETING OF THE INTERNATIONAL METALLOGRAPHIC SOCIETY, INC., CLEVELAND, OHIO, NOVEMBER 16–18, 1970. Johnson, K. A.; Bender, J. H. (eds.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971). 193p. (CONF-701118).

Twenty-five articles are included; separate abstracts were prepared for 10. One article on preparation of irradiated Liquid Metal Fast Breeder Reactor (LMFBR) prototypic fuels for metallography was previously included in NSA as 25: 22138. Abstracts only were included for two articles on transmission electron microscopy of boron carbide and effects of cold work and aging on the substructure and precipitation phenomena in the Co-base alloy L-605. The remaining 12 articles contained information on: effect of stress on precipitation in Type 316 stainless steel; a simplified electron probe microanalyzer; video techniques with an EM-200 electron microscopy; microstructural changes on austenitizing and tempering of M50 high-speed steel; phase identification etchants for Fe–Cr–Ni alloys; metallographic applications of xenon lamp systems; minimum error analysis for automatic image analyzing; metallography of rapidly solidified Al–Cu alloys; metallography of archeological artifacts; relation between ultrasonic scatter in the Rayleigh range and the metallographic structure of Al–Si alloys; exsolution in magnetite and ilmenite from granite and pegmatite; and metallography of barrier and sacrificial coatings. (P.C.H.)

For abstracts of individual papers see: 57627, 57693, 58174, 58190, 58353, 58354, and 58397–58400.

58397 EXAMINATION OF THE MICROSTRUCTURES OF MIXED URANIUM–PLUTONIUM DIOXIDE FUEL PELLETS FOR FAST FLUX IRRADIATION STUDIES. Chang, J. Y.; French, P. M.; Jacoby, W. R.; Shalek, P. D. (Westinghouse Electric Corp., Cheswick, Pa.). pp 41-56 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

Mixed-oxide fuel pellets of the composition $(U_{0.75}Pu_{0.25})O_{1.95 \text{ to } 1.99}$ and having nominal densities of 90 and 95% of theoretical were fabricated and characterized for fast flux irradiation studies in the EBR-II reactor. Metallographic, microhardness and autoradiographic data obtained at various stages in the program were used to identify the source and nature of secondary phases which could occur in the pellets. In addition, microstructural characteristics such as porosity and microcracking were found to be related to the type and method of binder addition as well as the preslugging and pelletizing pressures used in the fuel fabrication process. (auth)

58398 METALLOGRAPHIC ANALYSIS OF CERMET FUEL FORMS. Kelly, M. D.; Selle, J. E. (Monsanto Research Corp., Miamisburg, Ohio). Contract AT(33-1)-GEN-53. pp 89-93 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

Metallography was performed on solid solution cermet fuel forms used in radioisotopic heat sources. Coprecipitated PuO_2–ThO_2 solid solution shards were molybdenum coated and pressed into a pellet. During the development of the pressing parameters, cracking, graphite reactions, twinning, and other microstructures were observed. These structures and their causes along with the metallographic techniques are discussed. (auth)

58399 METALLOGRAPHIC ANALYSIS OF CARBIDE STRUCTURES IN CAST HEAT-RESISTANT ALLOYS. Price, C. W.; Johnson, D. W.; Beuhring, V. F. (Battelle Memorial Inst., Columbus, Ohio). pp 135-9 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

Extensive metallographic studies have been conducted on carbide structures in experimental iron, nickel, chromium cast heat-resistant alloys. These studies included optical metallographic, scanning electron microscopy (SEM), x-ray diffraction (XRD), and electron microprobe (EMX) analyses to determine the morphology and identity of the carbides. The most significant metallographic development in this work has been the utilization of backscattered electron (BSE) images from the SEM to obtain positive correlations between the various analytical techniques. The sensitivity of BSE images to chemical composition permits carbides of different compositions to be easily distinguished. BSE images of extracted carbides also permitted positive correlations between XRD, SEM, and EMX results. Stereoscopic examinations of the extracted carbides also provided a routine technique for determining the true morphology of the carbides. The results for specimens examined by these techniques are presented. (auth)

58400 MICRORADIOGRAPHIC STUDY OF FRACTURE IN BORON FILAMENT–ALUMINUM MATRIX COMPOSITE. Steele, J. H. Jr. (Virginia Polytechnic Inst., Blacksburg). pp 159-66 of Proceedings of the Third Annual Technical Meeting of the International Metallographic Society, Inc. /Johnson, K. A. (ed.). Los Alamos, N. Mex.; International Metallographic Society, Inc. (1971).

From third meeting of the International Metallographic Society; Cleveland, Ohio (16 Nov 1970).

A microstructural evaluation of fracture in unidirectional, continuous monolayer and bilayer boron filament–aluminum matrix composite was conducted using microradiography. Samples of the composite sheet were stressed in tension, and acoustic monitoring utilized to detect filament failure. Microradiographs were obtained with the samples maintained at constant elongation after filament damage was detected. This provided in-situ observation of filament failure within the composite. Samples with pre-induced cracks were tested and found to exhibit a filament break propagation mode of composite fracture. This failure mode which is characterized by fan-shaped fragmentation patterns was also observed for transverse fracture. Scanning electron micrographs indicated filament fragmentation with tensile shear behavior in the aluminum matrix. Frequency spectra obtained on typical acoustic emission data tend to indicate that transient resonant vibrations of the gage section are induced by filament fracture. The microstructural observations are discussed in terms of a filament break propagation mode of composite failure in this material. (auth)

58401 NEW PHASES IN THE Sc–V–O SYSTEM. Mikhailov, Yu. Ya.; Pokrovskii, B. I.; Komissarova, L. N. (Moscow State Univ.). Dokl. Akad. Nauk SSSR; 198: No. 2, 344-6(11 May 1971). (In Russian).

The results are presented for a phase equilibrium study at 1,000 to 1,500°C in portions of the Sc–V–O system and plotted on the bases of the oxides of Sc (3+), and V (3+, 4+). Only solid solutions are formed by the system Sc_2O_3–V_2O_3; the solubility of scandia in V_2O_3 is 5 mole % Sc_2O_3 at 1,000°C. Between the solid solutions lies a two-phase region which is reduced in size at 1,500°C, being bounded by the compositions 44 and 14 mole % Sc_2O_3. The compound Sc_2VO_5 was noted and the parameters of the elementary cell were measured: a = 6.854, c = 14.572, and z = 8; the pycnometric density was 4.10 g/cm^3. Several analogies to other systems are discussed. (K.S.W.)

58402 LATTICE PARAMETER AND DENSITY OF ZIRCONIUM HYDRIDE PHASE. Paetz, Peter; Luecke, Kurt (Interatom, Bensberg, Ger. Technische Hochschule, Aachen). Z. Metallk.; 62: No. 9, 662-4(Sep 1971). (In German).

The lattice constants of the three zirconium hydride phases given in the literature were investigated. According to the results, the supposition appears to be justified that only one single phase occurs whose lattice parameter varies continuously. The space diagonal assumes the significance of an invariant quantity. The density values determined from the lattice parameters agree well with the results of direct measurements. The dependence of the density on the hydrogen content exhibits kink points which delineate the phase fields of the zirconium-hydrogen system. (auth)

58403 TEXTURE PARAMETERS BY OPTICAL AND ELECTRON-MICROSCOPE PICTURES OF WC-, Co-, TiC-, AND TaC-

ALLOYS. Mader, W.; Mueller, K. F. Radex Rundsch.; No. 4, 286-96(Oct 1970). (In German).

For the examination of complex crystal structures a special etching method was developed. Texture parameters from optical and electron-microscope pictures were compared. Investigations were carried out into the relationships between the physical properties and the texture characteristics. (Metals Abstr.)

58404 CRYSTAL STRUCTURE OF GRAPHITE BROMINE LAMELLAR COMPOUNDS. Sasa, T.; Takahashi, Y.; Mukaibo, T. (Tokyo Univ.). Carbon; 9: No. 4, 407-15(Aug 1971).

The isotherm of bromine on pyrolytic graphite was studied at 20°C by stepwise bromination, and several phases of graphite bromide were identified, which had compositions of C_8Br, $C_{12}Br$, $C_{16}Br$, and $C_{20}Br$. X-ray studies showed that these possessed the socalled 2nd, 3rd, 4th, and 5th stage structures respectively. At bromine concentrations between these definite compositions, x-ray diffraction patterns showed mixtures of the higher stage and the lower stage structures. The density of the intercalated bromine molecules in a layer was believed to stay unchanged with the change of the composition. During the course of the reaction with the saturated vapor of bromine, an intermediate metastable lamellar compound structure was found in which the bromine layers were intercalated into every second layer spacing but for which the bromine concentration was believed to be much lower than that of C_8Br. (auth)

58405 PHASE EQUILIBRIA IN THE SYSTEM $BaO-CeO_2$. Guha, J. P.; Kolar, D. (Jozef Stefan Nuclear Inst., Ljubljana, Yugoslavia). J. Mater. Sci.; 6: No. 9, 1174-7(Sep 1971).

The phase equilibrium relationships in the binary system $BaO-CeO_2$ were investigated by thermal analysis, metallographic, and x-ray diffraction methods. The system is characterized by the existence of only one compound, namely, $BeCeO_3$ which is found to melt incongruently at 1480 ± 5°C with formation of solid CeO_2 and a liquid. A eutectic was found to occur between BaO and $BaCeO_3$ at 46 ± 0.5 mole % CeO_2 and its melting point was determined as 1440 ± 5°C. A narrow solid solubility range of BaO in $BaCeO_3$ exists, but no solid solubility of $BaCeO_3$ in either BaO or CeO_2 was detected. (auth)

58406 V–VO PHASE SYSTEM. Alexander, D. G.; Carlson, O. N. (Ames Lab., Iowa). Met. Trans.; 2: No. 10, 2805-11 (Oct 1971).

A phase diagram is proposed for the V–VO system based on melting point determinations, differential thermal analyses, metallographic observations, and x-ray parametric measurements. A eutectic reaction occurs at 1640°C and 29 at.% O. The intermediate phases V_9O and V_2O form peritectoidally at 510 and 1185°C, respectively, while V_4O forms by a peritectic reaction at 1665°C. The VO phase melts congruently at 1790°C. The terminal solubility of oxygen in vanadium increases from 3.2 at.% at room temperature to a maximum of 17.0 at.% at the peritectic temperature. There is also extensive solid solubility associated with each of the intermediate phases. Two martensite-like phases form in alloys in the composition range 6 to 9 at.% O upon quenching from above the 510°C peritectoid horizontal. (auth)

58407 ELECTRON MICROSCOPY OF HYDRIDE PRECIPITATION IN VANADIUM. Chiba, Toshinobu; Takano, Shigeo (Hokkaido Univ., Sapporo. Tokyo Univ.). J. Phys. Soc. Jap.; 31: No. 4, 1113-23(Oct 1971).

Precipitation of hydride from the solid solution of vanadium–hydrogen containing a small amount of hydrogen was observed at temperatures ranging between 300 and 77°K using the cold stage of a 500 kV electron microscope. Two types of precipitates were found at low temperatures. One has a cubic superstructure with a unit cell twice as large as that of vanadium matrix. The other has a tetragonal structure in which vanadium atoms form a body-centered tetragonal lattice with $c/a = 1.1$ to 1.3. On heating, these precipitates dissolved to the matrix at certain temperatures depending on the hydrogen concentration of the specimens. These facts give a direct confirmation to the postulation that the "anomalies" in vanadium metal are caused by the precipitation as the hydride phase of a trace of hydrogen involved. (auth)

58408 CONTRIBUTION TO THE EFFECT OF GAS PRESSURE IN PORES ON BOUNDARY MIGRATION AND GRAIN GROWTH IN SINTERED UO_2. Stevanovic, M.; Petrovic, V. Powder Met. Int.; 2: No. 2, 36-9(Jun 1970).

An investigation of the role of gas pressure in the retarding effect of pores on boundary migration and grain growth was carried out with specimens of sintered UO_2, obtained from green pellets to which different amounts of binder were added, and which were presintered in an atmosphere of H or CO_2. The specimens with different degrees of porosity, C content and different quantities of gases (products of C oxidation) in the pores, were heat treated between 1650 and 1800°C in He. An examination of microstructure and grain growth was conducted. (Metals Abstr.)

58409 THREE PHASE REGION IN TERNARY SYSTEM $UO_2-PuO_2-Pu_2O_3$. Fukushima, Susumu; Sasayama, Tatsuo; Kurihara, Masayoshi; Shimokawa, Junichi (Japan Atomic Energy Research Inst., Tokai). J. Nucl. Sci. Technol. (Tokyo); 8: No. 9, 534-5 (Sep 1971).

Phases observed in the $(U,Pu)O_{2-x}$ region containing Pu concentrations above 50% at room temperature are described. A constancy in the composition of phases found in this system is the basis for a model which substantiates a ternary $UO_2-PuO_2-Pu_2O_3$ structure. (J.R.D.)

58410 (BLG–456) GBR FUEL PIN TECHNOLOGY. Asbroeck, Van; Yellowlees, J. M. (Centre d'Etude de l'Energie Nucleaire, Mol (Belgium)). May 1971. 35p. (CONF-710326–2). Dep. NTIS (U. S. Sales Only).

From third meeting on fuel and materials; Brussels, Belgium (18 Mar 1971).

The Brussels Study Group of the Gas Breeder Reactor Association was given the task of performing a design study of a helium-cooled breeder reactor of 1000 MW(e) output. The fuel specification was to be based on mixed oxides of plutonium and uranium fabricated in the form of stainless steel clad fuel pins. The dimensional and mechanical stability of these fuel pins depends on fuel and clad properties which may be affected by a helium-cooled fast reactor environment. In order to make a choice of materials and to set down their properties for design purposes, the following items have received consideration: fuel swelling, fuel melting, fission gas release, fuel and gap conductivity, clad resistance to deformation, ductility, irradiation-induced swelling of stainless steel, and corrosion by helium or by fuel. Results of the study are the basis for fuel characteristics selection as follows: bulk density ≤ 90% theoretical density, diametral clad gap ≥ 2%, fuel swelling rate 0.5 to 0.7 volume percent per 10,000 MWd/te., AISI 316 L with an end-of-life ductility of 0.1% and an assumed maximum swelling of 9 volume per cent (for a fuel peak burn-up and fluence of 100,000 MWd/te 2×10^{23} n/cm^2 respectively). The low carbon version (AISI 316 L) is preferred to the standard alloy (AISI 316) since the former appears to have better resistance to corrosion by moist helium. As regards fuel/clad corrosion the reaction depth may be as high as 100μm at 700°C at the end-of-life. (auth)

58411 (GEAP–12217) FISSION GAS RE-SOLUTION RATES. Quarterly Report No. 4, April 1–June 30, 1971. Marlowe, M. O. (General Electric Co., Pleasanton, Calif. Vallecitos Nuclear Center). Jul 1971. Contract AT(04-3)-189. 8p. Dep. NTIS.

Progress in experimental programs and studies to determine the re-solution rates of fission gases in oxide nuclear fuels under irradiation are described. An intermediate specimen thinning technique with abrasive blasting was developed for use with the radioactive specimens. Three as-irradiated specimens were thinned by the abrasive blasting technique followed by ion milling in preparation for transmission electron microscopy. Five irradiated specimens were annealed at temperatures in the range 1300 to 1600°C. These specimens were pre-thinned to approximately 100 μm thick by metallographic polishing. (auth)

58412 MOBILITY AND PRECIPITATION OF RARE GASES IN SOLIDS DURING ANNEALING FOLLOWING ION BOMBARDMENT. Matzke, Hj. (European Inst. for Transuranium Elements, Karlsruhe, Ger.). pp 326-53 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

The available results on the mobility and precipitation of heavy inert gases (Ar, Kr, Xe, Rn) in solids are summarized and interpreted, using the recently established system of stages. Most studies have been performed on ionic crystals, but some ceramics (mainly nuclear materials, UO_2 and UC) and metals were investigated as well. The system of stages groups gas release processes in order of increasing temperature. The main components are: release of gas fortuitously located on high mobility sites; release of gas connected to annealing of gross structural damage, the most common form of which is bombardment-induced amorphousness; volume diffusion of single gas atoms; temporary

XUM

trapping of gas due to weak gas–gas or gas–damage interactions; strong gas–gas or gas–damage interactions and formation of gas-filled bubbles. Examples for all these stages and substages are given and empirical correlations for the relative importance, the temperatures for onset, and the activation enthalpies of the various stages are deduced. As far as possible, the atomic mechanism of rare gas mobility is described. Some still open questions and existing discrepancies are pointed out and suggestions are made for further work. 48 references. (auth)

58413 APPLICATION OF THE ION BOMBARDMENT TECHNIQUE TO STUDY THE BEHAVIOR OF RARE GASES IN UO_2. Matzke, Hj. (European Inst. for Transuranium Elements, Karlsruhe, Ger.). pp 354-91 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

The system of stages in gas release is used to predict the behavior and the mobility of fission rare gases in UO_2. The predictions are compared with literature data and with new experimental results. Stage IA is observed as expected as a fast release process at low temperatures, most probably involving release of gas situated in surface near atom layers. Stage IB release is predicted to be absent in UO_2, since due to the low recrystallization temperature of amorphous UO_2, no gross structural damage survives ion bombardment or reactor irradiation performed at or above room temperature. Ion bombardment work shows that Stages IIA and IIB due to mobility of the gas at the temperatures of self-diffusion yield, as expected, activation enthalpies of about 3.9 and 4.5 eV, respectively, the latter value being close to the most probable result for uranium self-diffusion (4.5 to 4.8 eV). Comparison is made with the extensive literature on reactor-irradiated UO_2. The most probable mechanism of Stage IIA, the diffusion of single gas atoms in virtually undamaged UO_2, is confirmed to be via Schottky trios, i.e., molecular voids in UO_2, by studying gas mobility in $UO_{2\pm x}$. Stage III, or the behavior of gas-filled bubbles, is discussed on the basis of results obtained both on ion-bombarded and reactor-irradiated UO_2, and the basic differences between laboratory annealing and in-pile annealing on the mobility of bubbles are given. (auth)

58414 URANIUM DIOXIDE FUEL PIN ELONGATION BEHAVIOR UNDER IRRADIATION. Ichikawa, Michio; Uchida, Masaaki; Morishima, Atsuyoshi; Taketani, Kiyoaki (Japan Atomic Energy Research Inst., Tokai). J. Nucl. Sci. Technol. (Tokyo); 8: No. 9, 528-30(Sep 1971).

Results of irradiation experiments in which the effects of burnup and pellet-clad clearances on the behavior of fuel pins are discussed. The effects of original pellet-clad clearance do not appear simultaneously after initiation of irradiation. With increasing burnup of the fuel, the heat rating necessary for the occurrence of pellet-clad interaction is lower. The permanent residual elongation of the pin increases linearly with burnup. (J.R.D.)

Plastics and Other Materials

58415 (FRNC-TH-61) DEFORMATION AND ULTIMATE STRENGTH OF A CONCRETE UNDER TRIAXIAL STRESS. Gachon, Herve (Paris Univ. (France). Faculte des Sciences). 5 May 1970. 62p. (In French). Dep. NTIS (U. S. Sales Only). Thesis.

The deformation and the ultimate strength of a prestressed concrete used in reactor vessels were studied. A machine for the triaxial stressing of concretes was developed. In the study of concrete deformation under a slow stress of short duration, three characteristic thresholds are observed: a reversibility threshold, a dislocation threshold and an ultimate strength threshold; this last threshold was studied in detail. (France)

58416 (RLO-2098-2) POLYMER GRAFTING TO INORGANIC SUBSTRATES. Annual Report, February 1, 1970–January 31, 1971. Raff, R. A. V.; Subramanian, R. V.; Schecter, D. J.; Adams, M. F. (Washington State Univ., Pullman. Research Div.). 31 Jan 1971. Contract AT(45-1)-2098. 64p. Dep. NTIS.

The effect of gamma radiation on a few polymer composites and on two metal–epoxy resin systems was studied. Considerable improvement in mechanical properties and increased creep resistance were observed in irradiated polymer composites of high or low density polyethylenes with long or short glass fiber, aluminum oxide, carbon black, silica, silica gel, sodium aluminosilicate, magnesium oxide, or calcium carbonate. Gamma radiation in the dose range 10^7 to 10^8 rads caused only deterioration in the strengths of specimens made from polystyrene, polystyrene–carbon black blends, polysulfone or polysulfone–glass fiber blends. The strength of joints of stainless steel to epoxy resin was found to be tripled after exposure to 6.0×10^7 rads. Similar results were observed with copper. (D.H.M.)

58417 GAMMA RAY-INDUCED DISORIENTATION OF POLYMER MOLECULES. Korodenko, G. D.; Karimov, S. N. (Tadzhik State Univ., Stalinabad, USSR). Dokl. Akad. Nauk Tadzh. SSR; 14: No. 3, 21-4(1971). (In Russian).

Oriented macromolecules were prepared by stretching polyvinyl alcohol samples at 120°C to 430%, and polyethylene samples to 900%. Infrared spectra and studies of dichroism showed that gamma-irradiated polymers developed network structures which opposed orientation. Radiation caused crosslinking in polyethylene resulting in a reduction of the intermolecular distance from 3 Å to 1.54 Å and disorientation of the polymer chains. (K.S.W.)

58418 $TlF–UF_4$ SYSTEM. Avignant, Daniel; Cousseins, J. C. (Univ., Clermont-Ferrand, France). Compt. Rend., Ser. C; 272: No. 26, 2151-3(28 Jun 1971). (In French).

The study of the $TlF-UF_4$ system by differential thermal analysis and x-ray crystallography led to the determination of the characteristics of the following phases: two polymorphic forms of Tl_4UF_8 and Tl_3UF_7, and two polymorphic forms of Tl_2UF_6 and $Tl_7U_6F_{31}$, $TlUF_5$, TlU_3F_{13}, and TlU_6F_{25}. The crystallographic characteristics of four of these phases were investigated: Tl_3UF_7 is cubic; Tl_2UF_6 at low temperatures is orthorhombic; and $Tl_7U_6F_{31}$ is rhombohedral; and TlU_6F_{25} is hexagonal. (France)

58419 RADIATION DAMAGE TO THE CRYSTALLINE STRUCTURE OF A GLASS-FORMING CHALCOGENIDE. Chen, C. W.; Bailey, D. M. (Ames Lab., Iowa). Radiat. Eff.; 10: No. 1-2, 65-9(Jul 1971).

Crystalline samples of a glass-forming chalcogenide, $As_{0.50}Te_{0.42}Ge_{0.08}$, have been irradiated by fast neutrons to the fluence of 3.4×10^{18} n/cm^{-2} (E > 1 MeV) at 83°K. X-ray diffraction examination indicated that such irradiation substantially destroys the crystalline structure. A recovery process was observed to occur at room temperature. However, 270 days after irradiation, the originally crystalline structure still remained severely damaged. The material appeared to be more susceptible to radiation damage than other solids at low temperatures. (auth)

58420 RADIATSIONNAYA STOIKOST' LAKOKRASOCHNYKH POKRYTII. (Radiation Stability of Lacquer Coatings). Knyazev, V. K. Moscow; Atomizdat (1971). 184p.

The use of lacquer coatings as a protective agent in industrial equipment and construction is discussed. The central theme, however, is the radiolysis of such films. Radiation-induced changes in polymeric materials are examined from several points of view: mechanical, physicochemical, and electrical. The sorption–desorption properties of coatings, and the practical use of lacquers in radiation fields and in the presence of radioactive contamination are considered. 202 references. (tr-auth)

58421 GLASS FOR NUCLEAR RESEARCH AND ENGINEERING. Kerntech. Atomprax.; 13: No. 7-8, 345-7(Jul-Aug 1971). (In German).

Glasses for nuclear research and engineering are discussed. Information is presented on the physical characteristics of specific types of glass used for radiation shielding, the equivalent lead thickness of glasses for shielding against radiation from a ^{60}Co source, the design and performance of composite glass windows for hot cells, glasses for dosimeters, and the use of glass pipes in reactors. (L.C.L.)

58422 ADVANCED COMPOSITE MATERIALS IN SPACECRAFT. Forest, J. D. Mod. Plast.; 47: No. 9, 136-7; 140 (Sep 1970).

Composite materials of B or graphite continuous filaments in a resin or metal matrix are promising for space vehicle applications such as cryogenic tankage, missile support systems, and antennas. Major advantages are the high strength and stiffness at low weight, the very low thermal distortion, and large weight savings. A table lists density, thermal-expansion coefficient, longitudinal and transverse tensile strength, and shear strength values for composites with epoxy or Al matrices. (Metals Abstr.)

58423 DISTRIBUTION OF TOTAL NITROGEN IN IRON METEORITES. Gibson, Everett K. Jr.; Moore, Carleton B. (Arizona State Univ., Tempe). Geochim. Cosmochim. Acta; 35: No. 9, 877-90(Sep 1971).

Total nitrogen abundances in 123 iron meteorites were determined by inert carrier–gas fusion extraction–gas chromatography. The median value for the iron meteorites was found to be 18 ppm N. The N contents of sulfide inclusions are greater, in nine cases out of ten, than the corresponding metallic phase. The N content of the iron meteorites is positively correlated with germanium content. The effects of terrestrial weathering and heat treatment by man are discussed in relation to the N contents measured for certain specimens. A correlation between N and cooling rates was found, with lower cooling rates associated with greater N abundances. (auth)

58424 NEUTRON STARS IN BINARY SYSTEMS SHOULD NOT BE PULSARS. Shvartsman, V. F. (Shternberg Astronomical Inst., Moscow. Inst. of Applied Mathematics, Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 342-3(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 438-40(Mar-Apr 1971).

Even a weak stellar wind from the normal component of a binary system would be capable of suppressing the ejection of material from a neutron-star component. Hence, neutron stars in binary systems could appear as pulsars only for a comparatively short time until the ejection has been replaced by accretion of material from the normal component. The pulsar would decay and an x-ray source would probably develop in its place. (auth)

58425 STABILITY OF A STAR WITH A PHASE CHANGE IN GENERAL RELATIVITY THEORY. Seidov, Z. F. (Shemakha Astrophysical Observatory, USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 347-8(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 443-5(Mar-Apr 1971).

On the basis of general relativity theory the critical value was found for the discrete change $q = \epsilon_2/\epsilon_1 = 3/2\,(1 + P_0/\epsilon_1)$ in the energy density (P_0 is the pressure at the phase transition) that would lead, through a phase change, to the loss of a star's stability at the point where the central pressure $P_c = P_0$. (auth)

58426 HYDROGEN LINES IN ENVELOPE OF NOVA HERCULIS 1934. Antipova, L. I. (Astronomical Council, Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 225-31(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 288-95(Mar-Apr 1971).

Possible mechanisms for the formation of the hydrogen absorption lines in the envelope of Nova Herculis 1934 (DQ Her) are discussed. It is found that the hydrogen absorption lines in the premaximum spectrum (at maximum light) and in the principal spectrum (after maximum) are broadened by the Stark effect. The principle of an optically thin layer yields the number of hydrogen atoms in the second quantum state along the line of sight, log $N_{0,2}H$, at the epoch when the premaximum spectrum was replaced by the principal spectrum. An estimate is obtained for the number $(N_{0,2}H)_{tot}$ of hydrogen atoms in the entire envelope at each epoch considered. These numbers are equal, affording direct support for Mustel's model, according to which the envelope detached from the star immediately after maximum light experiences a contraction. A comparison of the electron concentrations determined for the different dates further supports this conclusion. (auth)

58427 SIMPLE METHOD FOR DETERMINING PHOTOMETRIC ORBITAL ELEMENTS. Lavrov, M. I. (Kazan State Univ.). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 236-41(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 301-8(Mar-Apr 1971).

A new method for determining the photometric orbital elements of eclipsing binaries is proposed and tested successfully on the light curves of MN Cas, XZ Per, and FK Aql. The method has all the advantages attributed to the Kopal and Kopal–Piotrowski methods, but differs from them in its noteworthy simplicity for formulating and solving the basic equations. (auth)

58428 PURELY DISCONTINUOUS RANDOM PROCESSES IN AN IRREGULAR FORCE FIELD. III. VELOCITY VARIATION OF A STAR IN A QUASI-STATIONARY SPHERICAL CLUSTER. Petrovskaya, I. V. (Leningrad State Univ.). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 242-6(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 309-15(Mar-Apr 1971).

The second Kolmogorov–Feller equation is used to describe the evolution of the velocity distribution function of a star group in a quasi-stationary spherical system. The velocity distribution function of the field stars is assumed to vary homologously with time. The regular potential of the cluster is neglected. For a typical open cluster the time required for total dispersal is found to be $t = 31\,\tau_0$, where τ_0 is the relaxation time of the cluster at $t = 0$. The velocity distribution function, the proportion of stars evaporating (escape rate), and the proportion of energy removed by them are evaluated for the star group in question at different epochs. (auth)

58429 DENSITY DISTRIBUTION OF BRIGHT STARS IN THE GLOBULAR CLUSTER M56. Kholopov, P. N. (Shternberg Astronomical Inst., Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 247-9(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 316-19(Mar-Apr 1971).

Star counts to 16.7m pg demonstrate that the radius of the bright-star subsystem in the cluster M56 is 7.2, and the radius of the central nucleus zone is 0.9 pc. The logarithmic density range of this subsystem, $D_f = 3.5$, is nearly the same as the value for the subsystem of bright stars of constant luminosity in the cluster NGC 5466. (auth)

58430 STABILITY OF GLOBULAR CLUSTERS AND SPHERICAL GALAXIES. Fridman, A. M. (Inst. of Nuclear Physics, Novosibirsk, USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 250-2(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 320-2(Mar-Apr 1971).

A globular star cluster (or spherical galaxy) is modeled by a spherically symmetric system of rotating, gravitating masses. In accordance with observational evidence an r^{-2} density profile is adopted, with particle trajectories such that the total momentum of the system vanishes. The stability of such a model against arbitrary perturbations has been demonstrated on the basis of results from plasma physics; rigorous mathematical proofs of stability have been given elsewhere. (auth)

58431 POSSIBILITY OF A PULSED MASS OUTFLOW FROM A ROTATING MAGNETIC STAR. Ozernoi, L. M.; Usov, V. V. (Lebedev Inst. of Physics, Moscow. Moscow Technical Physical Inst.). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 187-9(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 240-3(Mar-Apr 1971).

The competition between two mechanisms of angular-momentum loss for a rotating magnetic star, deceleration due to stretching of the magnetic lines of force and mass outflow due to rotational instability, can under certain conditions result in an outflow of pulsed character. (auth)

58432 ULTRADENSE MATTER. Frautschi, S.; Bahcall, J. N.; Steigman, G.; Wheeler, J. C. (California Inst. of Tech., Pasadena). Comments Astrophys. Space Phys.; 3: No. 4, 121-6(Jul-Aug 1971).

It has recently been hypothesized that, beyond the low density region where present knowledge of nuclear forces suffices and the intermediate density region where present knowledge of forces among nucleons and light baryons is inadequate, there lies a third ultradense region where heavier baryons dominate and the description becomes simpler again. Two assumptions made in connection with this hypothesis are supported by three arguments and the Hagedorn level density is considered. (W.D.M.)

58433 LUMINOSITY OF HIGH-TEMPERATURE STARS. Cattani, M.; Fernandes, N. C.; Osada, J. (Univ., Sao Paulo, Brazil). An. Acad. Brasil. Cienc.; 42: No. 4, 677-8(Dec 1970).

Although the luminosity of normal stars has been extensively studied, there is no detailed work on the luminosity of very high-temperature stars, except for a simple order of magnitude estimate by Chin (1964). Since this problem is related to the problem of neutron stars, it is studied in some detail. (W.D.M.)

58434 PULSATIONS OF MASSIVE MAIN-SEQUENCE STARS. Clayton, D. D. (Rice Univ., Houston, Tex.). Comments Astrophys. Space Phys.; 3: No. 4, 127-31(Jul-Aug 1971).

XUM

Developments in the evolution, stability, dynamics, and pulsation mechanisms in massive main-sequence stars are reviewed. The relation of helium in the early stages of the Galaxy to these massive stars is discussed. (W.D.M.)

58435 TWO NEW CHAPTERS IN THE STORY OF U CEPHEI. II. Batten, Alan H. (Dominion Astrophysical Observatory, Ottawa); Plavec, Miroslav. Sky Telesc.; 42: No. 4, 213-15(Oct 1971).

New spectroscopic results indicate that a substantial quantity of dimly glowing gas is present in the space between the components of this eclipsing binary, particularly near the B6V star. This supports the conclusion, drawn from study of the period changes and from early spectroscopic work, that mass is being transferred from the G secondary to the B primary. (W.D.M.)

58436 STUDY OF THE BALMER ABSORPTION LINES OF NOVA HERCULIS 1963. Friedjung, M. (Institut d'Astrophysique, Paris). Astron. Astrophys.; 14: No. 2, 246-51(Sep 1971).

A study of line profiles of some spectra of Nova Herculis 1963 has led to demonstrations of the occurrence of inhomogeneities, and the importance of the ionization produced by the absorption of Balmer continuum quanta. (auth)

58437 IMPROVED METHOD FOR COMPUTING MEMBERSHIP PROBABILITIES IN OPEN CLUSTERS. Sanders, W. L. (Univ. of Chicago, Williams Bay, Wis.). Astron. Astrophys.; 14: No. 2, 226-32(Sep 1971).

Relative proper motions in the region of open clusters are fitted to a model by a maximum likelihood procedure for determining the frequency distribution function parameters for field and cluster stars. The clusters NGC 2168, 2281, 2420, 6633, 6823 and 7062 were re-examined for membership. (auth)

58438 SPECTRAL SYNTHESIS OF LOW-DISPERSION LUMINOSITY CRITERIA IN A- AND F-TYPE STARS. Bolton, C. T. (Univ. of Michigan, Ann Arbor). Astron. Astrophys.; 14: No. 2, 233-42(Sep 1971).

Synthetic spectra were computed for three regions, 4172-78 Å, 4417 Å, and 4481 Å, used for the luminosity classification of A and F stars on low-dispersion spectra. The ratio $\lambda4178:\lambda4172$ was found to be well correlated with surface gravity for stars with solar abundances. In the LTE approximation used the ratio $\lambda4417:\lambda4481$ was found to be at least as sensitive to microturbulence as it is to surface gravity. The NTE interpretation of this result is also discussed. Qualitatively, the behavior of these features in Am spectra are duplicated best by a model with $\log g = 4.3$, and abnormal abundances like those found by van't Veer–Menneret and Conti for 63 Tauri and the same microturbulence as in stars with solar abundances. The "anomalous luminosity effect" in Am stars between the ratios $\lambda4178:\lambda4172$ and $\lambda4417:\lambda4481$ is attributed to the abundance of iron and chromium being enhanced more in Am stars than the abundance of titanium. The consequences for spectral classification of possible variations of abundances and microturbulence at a given effective temperature and surface gravity are discussed. This investigation demonstrates that, even with the present limited knowledge of the values and ranges of such parameters as microturbulence and abundances as functions of effective temperature and surface gravity, spectral classification is a very powerful tool for studying stellar atmospheres. (auth)

58439 STELLAR GROUPS Ba 8, Ba 9, AND Be 68. Wagner, R. (Univ., Basel). Astron. Astrophys.; 14: No. 2, 283-92(Sep 1971).

Three-color photometry of these three stellar groups in the RGU system on plates taken with the 48-inch Palomar-Schmidt leads to the conclusion that they are physical groups at distances of 1320 pc, 5520 pc, and 3160 pc, respectively. The earliest color types are as follows: b 2 in Ba 9, a 0 in Ba 8, and b 8 in Be 68. Ba 8 and Be 68 include a red-giant branch. (auth)

58440 COMMENTS ON THE INSTABILITY STRIP FOR HALO POPULATION VARIABLES. Iben, Icko Jr.; Huchra, John (Massachusetts Inst. of Tech., Cambridge). Astron. Astrophys.; 14: No. 2, 293-310(Sep 1971).

Results of pulsation calculations in the linear, nonadiabatic approximation are presented. Major emphasis is placed on the location in the H–R diagram of the blue edges of the theoretical instability strip for pulsation in the first harmonic mode and in the fundamental mode. For a given composition, the luminosity and the period of the fundamental at the intersection of these two blue edges increase with increasing stellar mass. The slope of the relationship between period and luminosity defined by intersection points is similar to the slope of a transition curve that results from nonlinear calculations and has been used to estimate the absolute luminosity of RR Lyrae stars in globular clusters. It is suggested that the two curves are related. Pulsation results are compared with the observations and with the results of stellar evolution calculations in an effort to test this suggestion. (auth)

58441 SECOND-ORDER ROTATIONAL PERTURBATION OF NONRADIAL OSCILLATIONS OF A STAR. Smeyers, P.; Denis, J. (Katolicke Univ., Louvain, Belgium). Astron. Astrophys.; 14: No. 2, 311-18(Sep 1971).

The perturbation method is applied for the effects of a uniform rotation on nonradial oscillations of a star, up to the second order in the angular velocity. The distortion of the equilibrium configuration is taken into account by means of a transformation into spherical coordinates defined in a reference sphere and by means of a parallel displacement of the displacement vector, from the points of the spheroid into the points of the reference sphere. Numerical results obtained for a rotating homogeneous and compressible spheroid agree with values already known from other methods. The stabilizing effect of a slow uniform rotation on convection is corroborated. (auth)

58442 ORBITAL ELEMENTS OF THE SPECTROSCOPIC BINARIES HD 24733 AND HD 861. Acker, A. (Univ., Strasbourg). Astron. Astrophys.; 14: No. 2, 189-97(Sep 1971).

The radial velocity curve was determined for the spectroscopic binary HD 24733 from 97 observations made with the spectrograph C (telescope 120 cm O. H. P.) in September 1969 and January 1970. The orbital elements of HD 861 were determined from 14 observations made between 1968 and 1969, and 3 observations made in 1954 by Boulon. (W.D.M.)

58443 SPORADIC OUTBURSTS OF RED-DWARF STARS. Lovell, Bernard. Quart. J. Roy. Astron. Soc.; 12: No. 2, 98-132(Jun 1971).

This Presidential address was delivered on Feb. 12, 1971 under the following headings: flare stars; radio observations of the flares; spectral characteristics; light and radio emission curves of the flares; flare-star contribution to the galactic radio emission; energy of the out bursts; evolution of red-dwarf flare stars; theoretical considerations concerning the outbursts; and production of x rays and cosmic rays from flares. In conclusion it is suggested that these stars may be worthy of more attention than their inconspicuous nature suggests. They are truly stars in the early processes of birth; they are violently active in the optical and radio domains; they have stellar winds that contribute significantly to the interstellar medium; their integrated x-ray fluxes probably contribute a few percent of the total observed x-ray flux and may well be dominant in highly obscured regions like Taurus; and they are probably the source of very-energetic cosmic-ray protons. 58444 CNES AND SPACE ASTRONOMY. Blamont, J. E. (Centre National d'Etudes Spatiales, Paris). Rech. Spatial.; 10: No. 3, 1-5(May 1971). (In French).

The various fields of space astronomy studied by the CNES are briefly discussed and the experiments performed are reviewed. (France)

58445 STELLAR ULTRAVIOLET AND UV STARS. Gaide, Albert (European Space Research Organization, Paris). Rech. Spatial.; 10: No. 3, 8-10(May 1971). (In French).

The wavelength range of interest in uv astronomy is recalled and the results obtained in this range are briefly mentioned. (France)

58446 REDUCED HELIUM ABUNDANCES IN NEBULAE. Robbins, R. R. (Univ. of Texas, Austin); Daltabuit, E.; Cox, D. P. Astrophys. J.; 169: No. 2, L77-81(15 Oct 1971).

Recent capture-cascade calculations by Robbins and Robinson for the helium singlets, and also calculations by Cox and Daltabuit concerning collisional excitation in the helium triplets, imply a reduction in nebular helium abundances. For planetary nebulae, $\langle He/H \rangle \sim 0.081 \pm 0.03$ from singlet lines and 0.093 ± 0.02 from triplet lines, if all published data are used. Selecting the three best observed nebulae only, one finds $\langle He/H \rangle \sim 0.092 \pm 0.015$. For the Orion nebula, He/H ranges from 0.064 to 0.081 for various regions of the nebula. Some consequences of these reductions are discussed. (auth)

58447 SPECTRA OF WHITE DWARFS WITH CIRCULAR POLARIZATION. Greenstein, Jesse L.; Gunn, James E.; Kristian, Jerome (California Inst. of Tech., Pasadena). Astrophys. J.; 169: No. 2, L63-9(15 Oct 1971).

Spectra of circularly polarized stars, EG 248, GR 289, and EG 250 (Giclas G99–37, G99–47, and G195–19) were examined, together with spectrophotometric scans. It was confirmed that EG 248 has C_2 and CH, GR 289 apparently no features as yet detectable, and EG 250 possibly weak C_2 and, less certainly, shallow depressions (probably metallic lines) in the violet. Their mean absolute magnitudes were estimated to be between +12 and +15. Stars of similar color and luminosity have relatively easily visible lines. It is suggested that circularly polarized degenerate stars are convective, diluting surface hydrogen and bringing unusual elements to the surface from what were cores of old red giants. (auth)

58448 SOLID-STATE ASTROPHYSICS. Salpeter, E. E. (Cornell Univ., Ithaca, N. Y.). pp 75-80 of Methods and Problems of Theoretical Physics. /Bowcock, J. E. (ed.). New York; American Elsevier Publishing Co., Inc. (1970).

From Conference on methods and problems of theoretical physics; Birmingham, England (Jun 1967).

In certain types of very dense stars the nuclei form a lattice and, in some ways, such a "stellar solid" is simpler to treat than the familiar solids. A short review of this subject is given. (W.D.M.)

58449 SOME RED GIANTS OF THE OLD DISK POPULATION. Eggen, O. J. (Australian National Univ., Canberra). Publ. Astron. Soc. Pac.; 83: No. 494, 423-32(Aug 1971).

(UBVRI) photometry and space motions of several old disk population red stars are presented. These stars include 14 new variables. (auth)

58450 OBSERVATIONS OF THE RECOVERY AND FINAL DECLINE OF NOVA SERPENTIS 1970. Borra, Ermanno F. (Univ. of Western Ontario, London). Publ. Astron. Soc. Pac.; 83: No. 494, 447-8(Aug 1971).

Ten nights of photoelectric observations of Nova Serpentis 1970 are presented. Three spectrograms in the nebular stage were taken. After a small brightening, Nova Serpentis 1970 appears to be declining slowly towards minimum. (auth)

58451 MONOCHROMATIC REFLECTION EFFECT OF CLOSE BINARY STARS. Chen, Kwan-yu (Univ. of Florida, Gainesville); Rhein, Walter J. Publ. Astron. Soc. Pac.; 83: No. 494, 449-58(Aug 1971).

The stars of a binary system are assumed to exchange radiation like spherical black bodies with limb darkening. The temperatures of the facing surfaces are calculated as functions of the radii, the intrinsic temperatures, and the coefficients of limb darkening of the two stars. The light curves, neglecting eclipses, are then calculated as functions of the wavelength of the radiation, the inclination of the system and its phase, using numerical integration on a digital computer. The geometrical model of the system is exact and allows calculations to be made for close binary systems. The orbit is assumed to be circular. Results for several typical close binary systems are shown. Comparisons are made with the light curves of several observed close binaries. (auth)

58452 UBV PHOTOMETRIC STUDY OF HS HERCULIS. Hall, Douglas S.; Hubbard, G. Scott (Vanderbilt Univ., Nashville). Publ. Astron. Soc. Pac.; 83: No. 494, 459-70(Aug 1971).

About 250 new UBV observations are presented. A photometric complication, which causes maximum brightness after secondary minimum to be retarded until about 0.7^p, was observed on two separate nights and was strongest in U. Ignoring $0.5^p < p < 0.7^p$ and assuming $x_s = x_g = 0.6$, the solution $k = 0.55$, $r_g = 0.259$, $j = 88.7°$, and $L_h = 0.900, 0.915, 0.932$ in V, B, U, respectively, was obtained. (B – V) and (U – B), corrected for reflection, implied B4 ± 1 and A4 ± 1 for the primary and secondary, with $E(B - V) = 0.15m$. With the mass function of Cesco and Sahade and the mass–luminosity relation of Iben applied to the hot star, the absolute dimensions $4.7\,\mathfrak{M}_\odot$, $2.8\,R_\odot$ and $1.6\,\mathfrak{M}_\odot$, $1.6\,R_\odot$ for the primary and secondary, respectively, were derived. The orbital period is variable and only apsidal motion, with a period of $15\frac{1}{2}$ years, can explain the available times of minimum and the spectroscopic elements. With HS Herculis detached and with both stars clearly on the main sequence, circumstellar material was not expected and the photometric complication was puzzling. A model is proposed in which a cloud is situated within the Roche lobe of the cool star near the conical point, and it is speculated that such a cloud might be the remains of a disk-like cloud such as surrounds the much younger binary BM Orionis. (auth)

58453 RED RR LYRAE VARIABLE DK VELORUM. Jones, D. H. P. (Australian National Univ., Canberra). Publ. Astron. Soc. Pac.; 83: No. 494, 471-3(Aug 1971).

DK Vel appears to be a short-period, metal-rich variable, cooler than any other RR Lyrae star. (auth)

58454 PHOTOMETRY OF THREE PECULIAR A-TYPE STARS. Morrison, Nancy D.; Wolff, Sidney C. (Univ. of Hawaii, Honolulu). Publ. Astron. Soc. Pac.; 83: No. 494, 474-7(Aug 1971).

Four-color (uvby) photoelectric observations yielded provisional periods for three peculiar A-Type stars. For 108 Aquarii, the period was 3.73d. For HD 184905, the period was either 1.84 or 2.17d, and for θ^1 Microscopii the most probable periods were 0.941 and 1.062d. (auth)

58455 FAINT SUPERNOVA IN AN ANONYMOUS SOUTHERN GALAXY. Van Agt, Steven; Coutts, Christine (Univ. of Toronto). Publ. Astron. Soc. Pac.; 83: No. 494, 478(Aug 1971).

On a series of 11 Curtis Schmidt plates of the Sculptor dwarf galaxy obtained between Aug. 4 and 11, 1970, a supernova was found at $\alpha = 1$ h 1.8 m, $\delta = -35°22.8'$ (1950). It is located in a spiral arm of a faint anonymous galaxy of Type Sc II, 17″ north and 0″ west of the nucleus $m_J = 18.8 \pm 0.4$m.

58456 SUBLUMINOUS B-TYPE STAR CD -42^0 14462. Bond, Howard E.; Landolt, Arlo U. (Louisiana State Univ., Baton Rouge). Publ. Astron. Soc. Pac.; 83: No. 494, 485-7 (Aug 1971).

Observations of the tenth-magnitude, newly discovered peculiar B-type star CD−42°14462 are described. Photometrically this object shows a large ultraviolet excess, and its spectrum contains only broad and shallow absorption lines of H and He I. It may be related to the white-dwarf stars, and certainly it is one of the brightest of the subluminous stars now known. (auth)

58457 UBV OBSERVATIONS OF VISUAL DOUBLE STARS. Lutz, Thomas E. (Washington State Univ., Pullman). Publ. Astron. Soc. Pac.; 83: No. 494, 488-90(Aug 1971).

UBV magnitudes were obtained at Kitt Peak for 28 visual binaries. The magnitudes and color indices are tabulated. (W.D.M.)

58458 FOUR SUSPECTED SPECTROSCOPIC BINARIES IN THE PLEIADES. Pearce, J. A.; Hill, Graham (Dominion Astrophysical Observatory, Ottawa). Publ. Astron. Soc. Pac.; 83: No. 494, 493-5(Aug 1971).

Radial velocities are presented for four suspected spectroscopic binaries in the Pleiades. Published elements are confirmed for one object, yet another may be variable, and two are probably constant velocity objects. (auth)

58459 TECHNETIUM IN THE MIRA VARIABLE RZ PEGASI. Peery, Benjamin F. Jr. (Indiana Univ., Bloomington); Keenan, Philip C.; Marenin, Irene R. Publ. Astron. Soc. Pac.; 83: No. 494, 496(Aug 1971).

Absorption lines of technetium appear in considerable strength in the spectrum of RZ Pegasi (P = 439d) as photographed with the 200-inch coudé spectrograph on Sept. 18, 1970, three weeks after maximum. In the reproduction the positions of the three zero-volt lives of Tc at $\lambda\lambda$ 4238.191, 4262.270, and 4297.098 are indicated. (W.D.M.)

58460 RADIAL VELOCITY OBSERVATIONS OF THE DELTA SCUTI STAR 20 CANUM VENATICORUM. Penfold, J. E. (Univ. of Victoria, B. C.). Publ. Astron. Soc. Pac.; 83: No. 494, 497-501(Aug 1971).

Radial-velocity observations of the Delta Scuti star 20 CVn taken over four nights indicated a probable variable radial velocity with an amplitude of about 1.5 km/sec. An attempt to determine the period resulted in two estimates, viz. 0.135 and 0.176d. The former value appears to fit the data slightly better and is suggested as the true period. Photometric observations in the V band obtained on one of the nights show that maximum light apparently occurs on the rising branch of the velocity curve near minimum velocity. (auth)

58461 HD 21242: A SPECTROSCOPIC BINARY WITH H AND K EMISSION. Carlos, Robert C.; Popper, Daniel M. (Univ. of California, Los Angeles). Publ. Astron. Soc. Pac.; 83: No. 494, 504-7(Aug 1971).

Orbital elements are given for the spectroscopic binary HD 21242, (6.5m, G5V). The period is 6.4d. The cooler component has strong Ca II emission with the same velocities as its absorption lines and is slightly more massive than the G5 star. HD 21242 is a noneclipsing counterpart of a sizable group of eclipsing binaries. (auth)

58462 EVIDENCE FOR PRODUCTS OF RAPID NEUTRON CAPTURE ON THE SURFACES OF PECULIAR A STARS. Kuchowicz, B. (Univ., Warsaw). Astrophys. Lett.; 9: No. 2, 85-9(Sep 1971).

XUM

Observations indicate the presence of the unstable element promethium, as well as of certain products of rapid neutron capture in peculiar A stars. An analysis of these features indicates the possible presence of the heaviest elements (from the hypothetical island of stability around Z = 114) in the surfaces of these stars. Observational results concerning some specific abundance correlations (e.g. between promethium, uranium, and plutonium in the same star) are desirable to prove the hypothesis. (auth)

58463 TRANSFORMATION OF THE STELLAR WIND EQUATIONS. Roberts, P. H. (National Center for Atmospheric Research, Boulder, Colo.). Astrophys. Lett.; 9: No. 2, 79-80(Sep 1971).

A simple transformation is demonstrated which reduces the number of parameters in the stellar wind equations from two to one. (auth)

58464 PHOTOMETRIC OBSERVATIONS OF SUPERNOVA 1971 IN NGC 4165. de Vaucouleurs, G.; de Vaucouleurs, A.; Brown, G. S. (Univ. of Texas, Austin). Astrophys. Lett.; 9: No. 2, 77-8(Sep 1971).

UBV photometry of the supernova in NGC 4165 on April 23, 24, 26, and 27, 1971, gives results consistent with a Type I supernova that reached a maximum m = 13.2 ± 0.2 (B) on April 11 ± 2. The total magnitudes and colors of the galaxies measured through an aperture of 2.50 arc min are $V_t = 13.57$, $(B-V)_t = +0.74$, $(U-B)_t = +0.21$. (auth)

58465 MULTIPLICITY OF SOLUTIONS FOR THE EQUILIBRIUM MODELS OF A HELIUM-BURNING POPULATION I STAR. Kozlowski, Maciej (Univ., Warsaw). Astrophys. Lett.; 9: No. 2, 65-7(Sep 1971).

A nonevolutionary sequence of static models for a helium-burning star of 10 $M_\odot$ is constructed. Along this sequence the Vogt-Russell theorem is not valid. For a certain range of helium core masses it is possible to construct three different models of a star with a given total mass and a given chemical structure. These models possess different parameters at the surface but identical parameters at the center. One model is a cool supergiant with a deep convective envelope, the second one has a high effective temperature, and the third lies between them on the H-R diagram. It is suggested that the erratic behavior of the evolutionary tracks computed for models burning helium in the core may be partly due to the existence of multiple solutions of stellar structure equations. (auth)

58466 SEARCH FOR SOUTHERN OH-IR OBJECTS. Caswell, J. L.; Robinson, B. J.; Dickel, Helene R. (CSIRO, Sydney). Astrophys. Lett.; 9: No. 2, 61-4(Sep 1971).

A search was made for 1612-MHz OH emission from 94 long-period variable stars in the southern sky. V Microscopii gave the only positive detection. In addition, a new 1612-MHz emission source (OH338.5 + 0.1) with the characteristics of an OH-ir object was discovered by chance; at this position no long-period variable is known and no ir object has yet been found. (auth)

58467 SOLUTION OF NON-LTE TRANSFER PROBLEMS. Avrett, Eugene H. (Smithsonian Astrophysical Observatory, Cambridge, Mass. Harvard Coll. Observatory, Cambridge, Mass.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 511-29(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

In the outer layers of a stellar atmosphere, the radiation at line and continuum wavelengths strongly influences the relative number of atoms in various states of excitation and ionization. Conversely, the radiation at a given point often depends on the atomic populations throughout a large surrounding region. Therefore, one has a local dependence of n_i on I_v, together with a nonlocal dependence of I_v on values of n_i. Various procedures involving either differential equations or integral equations can be used to solve for either I_v or n_i. The main topic of this review is the integral-equation approach, with emphasis on numerical methods developed in recent years for the solution of physically realistic problems. (auth) (UK)

58468 RADIATIVE TRANSFER IN TWO-COMPONENT STELLAR ATMOSPHERES. Avrett, Eugene H.; Loeser, Rudolf (Smithsonian Astrophysical Observatory, Cambridge, Mass.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 559-71(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

A method is described for solving the line-transfer equations for a two-component atmosphere consisting of an array of columns, characterized by a particular variation of temperature with height, that are embedded in a medium in which the temperature is a different function of height. Radiative interaction between the two regions is taken into account, and the opacity is allowed to vary arbitrarily with depth. Some calculations that correspond to the solar Ca K-line are described. (auth) (UK)

58469 STELLAR ATMOSPHERES PROBLEM. Auer, L. H. (Yale Univ., New Haven). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 573-87(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

The construction of model stellar atmospheres is discussed placing particular stress on the mathematical methods used. The basic equations and assumptions of the problem are presented. Techniques which reduce the transfer equation to a set of linear equations are developed. It is shown how the constraint of radiative equilibrium may then be included directly into the transfer equation, yielding much more powerful methods for constructing model atmospheres than previously available. The scheme where all equations and constraints are solved simultaneously via full linearization is also given, and possibilities for improvement are briefly discussed. (auth) (UK)

58470 A MODIFIED FEAUTRIER METHOD. Rybicki, G. B. (Smithsonian Astrophysical Observatory, Cambridge, Mass.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 589-95(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

A modification of the Feautrier method of solving transfer problems is presented that allows advantage to be taken of such simplifications as isotropic scattering and complete frequency redistribution. The method has timing and storage requirements comparable to integral equation methods, but retains the ease of formulation of differential methods. The case of a two-level atom is treated in detail, and an appropriate generalization is sketched for the treatment of multi-level cases by means of a complete linearization technique. (auth) (UK)

58471 GREY RADIATIVE TRANSFER. Pomraning, G. C. (Science Applications, Inc., La Jolla, Calif.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 597-615(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

The general problem of reducing a frequency-dependent radiative-transfer problem to an equivalent grey problem is discussed. In particular, an asymptotic solution is constructed from the integral transport equation to be used in forming grey opacities. This is closely related, but not identical, to the so-called B-N method widely used in neutron transport work. This leads to generalizations, to nonzero temperature gradients, of the standard Planck and Rosseland mean opacities. The mean opacities relevant to higher angular moments of the equation of transfer are also obtained. It is shown how the angular dependence of this asymptotic result can be incorporated into the grey equation of transfer without introducing an angularly dependent opacity. It is only necessary to modify the scattering kernel. The dominant term in the modification depends upon the difference between the Planck and Rosseland mean opacities. The resulting grey equation is shown to be exact in the two limiting cases of optically thin and thick systems where it is well known that the standard Planck and Rosseland means, respectively, are the appropriate averages. Numerical results are presented for idealized absorption coefficients, such as the Elsasser band (an infinite array of equally spaced, equal strength Lorentz lines) and a $1/v^3$ behavior (characteristic of bound-free and free-free transitions). The generalized Planck and Rosseland means are calculated and their dependence upon the temperature gradient exhibited. Results from the grey equation of transfer are compared with an exact frequency-dependent result for a model problem and shown to be significantly more accurate than those predicted by the usual grey models employing the standard Planck and Rosseland means. All of the considerations apply to the formation of a multigroup equation of transfer as well as to a grey, or one group, equation. (auth) (UK)

58472 SOME ASPECTS OF THE NON-LTE PHYSICS OF THE HELIUM ATOM IN HOT STARS. Underhill, A. B.; Hearn, A. G. Sonneborgh Observatory, Utrecht. Observatoire de Nice). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 617-22(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

In the atmospheres of the hot stars (types O and B), the populations of the states of the helium atom are significantly different from the LTE populations. This not only gives a change in the line source function with a consequent change in the predicted line depths, but it also changes the scale of the optical depths in the lines, with a consequent change in the deduced abundance of helium. Some exploratory numerical results are given to illustrate these effects, which could explain the observed variations of the strengths of the He I and He II lines in O and B type stars. There is an important coupling between the intensities of the He I lines in the visible region of the spectrum and radiation densities at wavelengths less than 584 Å. (auth) (UK)

58473 LINE AND CONTINUUM PROBLEMS IN GASEOUS NEBULAE. Osterbrock, D. E. (Univ. of Wisconsin, Madison). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 623-39 (Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

Gaseous nebulae are effectively transparent to nearly all the strong emission lines in the ordinarily observed spectral region, and if the physical conditions are known the calculation of the expected spectrum simply becomes a calculation of emission coefficients, without any intervention of radiative-transfer theory. For this reason astronomers tend to think of stellar- or planetary-atmosphere problems when they think of applications of radiative transfer theory. There are many important nebular radiative-transfer problems, particularly those of the ultraviolet continuum and resonance lines, which in fact fix the physical conditions throughout the nebula. Some of these problems are reviewed. (auth) (UK)

58474 RADIATIVE-TRANSFER EFFECTS IN CEPHEID ATMOSPHERES. Davis, Cecil G. Jr. (Los Alamos Scientific Lab., N. Mex.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 647-53(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

The transfer equation, without retardation and considering scattering as absorption, is transformed by the moments expansion method for use in studying the dynamics of Cepheid atmospheres. The 0th and 1st moment equations are solved implicitly, using a variable Eddington factor (f) and 13 frequency groups. The f is calculated each time step by a characteristic ray plane transfer method. Results in a "bump" model (3.52 M_θ, $T_{eff} = 4585°K$) of R. Christy are presented and are compared to an observed 10.9 period Cepheid, V.X. Per. (auth) (UK)

58475 ECLIPSING VARIABLE IU AURIGAE. Mayer, P. (Charles Univ., Prague). Bull. Astron. Inst. Czech.; 22: No. 4, 168-87(1971).

UBV observations of IU Aur made in the years 1964 to 1971, numbering nearly 2500, are presented. Several new minima times are given and a periodic term in light elements is suspected. Color behavior can be explained by a third body light with an intensity about 0.20 (in V color); MK spectral type of the variable is B0:p:. The most interesting feature is perhaps the growth of minima depths: the depth of a primary minimum in V color in 1964 was about 0.470^m_u, in 1970 0.545^m_u. An orbital plane precession caused by the third body is probably responsible for it. (auth)

58476 EFFECTIVE TEMPERATURES AND GRAVITIES FOR A- AND F-TYPE STARS IN THE DELTA SCUTI REGION. Dickens, R. J; Penny, A. J. (Royal Greenwich Observatory, Sussex, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 287-302(1971).

Effective temperatures and surface gravities are derived from spectrophotometry between 3500 Å and 8000 Å for 31 A- and F-type stars in or near the Delta Scuti region of the HR diagram. The stars include four Delta Scuti variables and ten stars known to be nonvariable. Excellent agreement is obtained with temperatures derived from VRI photometry. A brief discussion of the properties of all known variable and nonvariable stars in this region for which temperature, gravity, and an independent measurement of the absolute magnitude are available is given. Masses for the stars are poorly determined but are reasonably consistent with those expected for hydrogen-burning stars evolving off the main sequence. (auth) (UK)

58477 WOLF-RAYET STARS IN H II REGIONS. Crampton, David (Dominion Astrophysical Observatory, Victoria, British Columbia). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 303-14 (1971).

A catalogue of WR stars coincident with H II regions is presented. Approximately 44% of the WR stars surveyed are found to be "possibly" associated with nebulosity while the association is considered to be "probable" for 25% of the cases. Although the absorption derived from the WR stars is comparable to that from the OB stars in H II regions, the WR distance moduli are about one magnitude larger than those derived from the OB stars. An average decrease of 0.8 mag in the absolute magnitudes of galactic WR is indicated in apparent disagreement with the luminosities derived from WR stars in the Large Magellanic Cloud. A list of WR stars in open clusters is also given. (auth)

58478 UBV AND Hβ PHOTOMETRY OF THE ECLIPSING BINARY S VELORUM. Sistero, R. F. (Univ. Nacional, Cordoba, Argentina). Bull. Astron. Inst. Czech.; 22: No. 4, 188-96 (1971).

Photoelectric observations of 750 U, B, and V magnitudes and 39 Hβ strengths of the binary system S Vel are presented. The period of the system (5.9336663d) and orbital elements were studied. In combining photoelectric and spectroscopic elements the absolute dimensions are discussed. The system is an Algol-type binary with a normal A5 main-sequence primary component and a K5 undermassive secondary subgiant. (auth)

58479 DISSOCIATION EQUILIBRIUM OF SOME DIATOMIC MOLECULES IN DELTA CEPHEI. Pande, M. C.; Tripathi, B. M.; Murthy, C. S.; Gaur, V. P. (Uttar Pradesh State Observatory, Naini Tal, India). Bull. Astron. Inst. Czech.; 22: No. 4, 196-9 (1971).

The dissociation equilibrium of CO, CN, C_2, CH, NH, and OH is considered for the maximum and minimum phases of the light curve of δ Cep. Concentration-optical depth curves show that with both the phases the abundances decrease in the order CO, OH, CH, NH, CN, and C_2. The amplitude of the abundance variation decreases in the order CO, CN, C_2, OH, NH, and CH. (auth)

58480 INVESTIGATION OF THE CONSISTENCY OF THE CALIBRATIONS OF THE uvbyβ AND gnkmf PHOTOMETRIC SYSTEMS. Olsen, E. H. (Lowell Observatory, Flagstaff, Ariz.). Astron. Astrophys.; 15: No. 1, 161-72(Nov 1971).

Wide physical binary stars with G or K giant stars as primary components and A or F main-sequence stars as secondary components were observed photoelectrically; the primary components in the narrow-band gnkmf photometric system and the secondary components in the uvbyβ photometric system. Data in the gnkmf system are given for 32 double star components and data in the uvbyβ system for 34 double star components. (W.D.M.)

58481 DETERMINATION OF ATMOSPHERIC PARAMETERS FOR G AND K GIANTS BY MEANS OF PHOTOELECTRIC INDICES. Hansen, L; Kjaergaard, P. (Copenhagen Univ. Observatory). Astron. Astrophys; 15: No. 1, 123-60(Nov 1971).

The narrow-band photometry published by Dickow et al. (1970) was used for calibration of atmospheric parameters for G and K giants. It is shown that the dwarfs can be distinguished from the giants, and that stars with indices affected by interstellar reddening or duplicity can be eliminated. R – I and [Fe/H] are assumed to represent effective temperature and chemical composition, while a residual Δn from a relation between the cyanogen index n, R – I, and [Fe/H] is assumed to measure surface gravity. Calibrations giving R – I and $M_v(K)$ as functions of the observed indices are derived for giants in the intervals $0.40 < R - I < 0.65$ (G8–K3) and $0.65 < R - I < 0.88$ (K4–K5). Three calibrations giving [Fe/H] of the same indices are obtained for the G8–K3 giants (estimated standard deviation of the mean: 0.08); one of these calibrations may be extrapolated to the K4–K5 giants. Furthermore, [Na/H] can be derived for the G8–K3 giants from the above mentioned indices and the Cambridge ratio Na D. (auth)

58482 ACTIVITY PHASE OF CH CYGNI DURING THE PERIOD 1967 TO 1970. Faraggiana, R.; Hack, M. (Astronomical Observatory, Trieste, Italy). Astron. Astrophys.; 15: No. 1, 55-76(Nov 1971).

The spectrum of CH Cygni during the period July 1967–December 1970, following the explosion of June 1967, was studied using high-dispersion spectrograms. The main characteristics are discussed. (W.D.M.)

58483 OBSERVATIONS OF O AND Of STARS. Heap, S. R. (Univ. of California, Los Angeles). Astron. Astrophys.; 15: No.1, 77-89(Nov 1971).

Spectrograms with a dispersion of 16.2 Å/mm covering the spectral range λ3300 to λ4900 were obtained for three early O stars and three early Of stars. Detailed line profiles of selected hydrogen and helium lines were obtained, and equivalent widths of nearly all visible lines were measured. Comparison of the spectroscopic properties between Of stars and O stars suggest that Of stars have lower surface gravities than do O stars. Comparison of their photometric properties confirms this suggestion. Hence, present temperatures scales for O5–O8 stars should not be applied to Of stars until the effect of gravity in determining

XUM

spectral type has been determined. In addition, the spectra suggest that atmospheric models of Of stars should take into account spherical and hydrodynamic effects. (auth)

58484 LINE BLANKETED MODEL ATMOSPHERE FOR ϵ VIRGINIS (HD 113226). Morgan, Thomas Edward. Bloomington, Ind.; Indiana Univ. (1971). 119p. University Microfilms Order No. 7117,451.

Thesis.

Using the line blanketing developed by Mutschlecner and Keller (Solar Physics, in press), LTE model bracketing of the previously derived parameters of ϵ Vir ($T_{eff} = 4940$ K, log g = 2.7) was completed. The effects of blanketing on predicted quantities were studied by means of the continuum energy distribution, broad- and intermediate-band multicolor magnitudes, and profiles of several strong absorption lines. In addition, the effect of line blanketing on the temperature–pressure structure of the models was investigated, and the present technique is compared with other blanketing methods suggested for cool stars. 58485 ATMOSPHERES OF PULSATING STARS. Stepien, Kazimierz (Astronomical Observatory, Warsaw). Postepy Astron.; 19: No. 3, 225-45(1971). (In Polish).

Observational data on pulsating stars are given. They are mainly spectrophotometric observations by Oke's group and photometric and spectroscopic observations by Preston's group. Evidence is presented that shock waves develop in the atmospheres of W Virginis stars and some RR Lyrae stars. A numerical kinematic model of W Virginis developed by Whitney is presented. This model is based on the assumption that the flux of strong shock waves is applied to the atmosphere of a W Virginis cepheid. Recent results on models of a δ Cephei-type star are discussed. Thick-zone models with the diffusion approximation of radiation transfer are compared with the thin-zone models in which the transfer equation is solved explicitly and with a set of static models computed with instantaneous values of effective gravity and of effective temperature. No large differences are found. (auth)

58486 PRESSURE INSIDE A ROTATING STAR. Abramowicz, M. A. (Zaklad Astronomii, Warsaw). Postepy Astron.; 19: No. 3, 247-53(1971). (In Polish).

The pressure decreases outward inside any rotating, relativistic star. (auth)

58487 SPACE DISTRIBUTION OF EVOLVING STARS IN M13. Blaghikh, Assia; Castellani, Vittorio (Univ., Rome). Astrophys. Space Sci.; 12: No. 1, 208 18(Jul 1971).

Information about space distribution was collected for selected classes of evolving stars in the globular cluster M13. After a rigorous elimination of field stars, three samples were examined, corresponding to the red giant stage (G), the blue (B), and the yellow (YG) parts of the horizontal branch. It is shown that results are easy to understand in terms of: (i) A substantial mass loss in the H-shell burning stage; (ii) Evolution along the horizontal branch from the blue side to the red one; and (iii) A mixing in the observed giant branch of two populations with sensible differences in masses. Theoretical interpretations are briefly discussed with reference to the reliability and usefulness of this type of investigation. (auth)

58488 STUDY OF THE WAVELENGTH DEPENDENCE OF INTERSTELLAR POLARIZATION USING A SCANNING SPECTROPOLARIMETER. Wolstencroft, R. D.; Nandy, K. (Royal Observatory, Edinburgh). Astrophys. Space Sci.; 12: No. 1, 158-64(Jul 1971).

A scanning spectropolarimeter was constructed and used in a preliminary search for conspicuous features of the interstellar polarization curve between $\lambda^{-1} = 1.58\ \mu^{-1}$ and $2.50\ \mu^{-1}$. The instrument was used at the f/4.5 prime focus of the 36" telescope of the Cambridge University Observatories. Scans were made on HD2905, HD21389, α And, and β Tau with slitwidths of 50 Å and 100 Å. The commonly adopted method of correcting for instrumental polarization by using observations of unpolarized stars was applied. The normalized polarization curves corrected for instrumental polarization for HD2905 and HD21389 reveal a feature near $\lambda^{-1} = 1.68\ \mu^{-1}$ which is most probably of interstellar rather than instrumental origin. (auth)

58489 INTRINSIC VARIATIONS OF INTERSTELLAR EXTINCTION LAWS. Nandy, K.; Napier, W. M.; Thompson, G. I. (Royal Observatory, Edinburgh). Astrophys. Space Sci.; 12: No. 1, 151-7(Jul 1971).

The intrinsic ultraviolet colors of early-type stars were derived from the rocket data of Campbell and Smith. There was a considerable spread in these colors. One possible source is the predicted rms variation due to the effect of rotation. It is necessary to recognize that rotation is an important source of uncertainty of the interstellar extinction curves derived from the comparison of pairs of stars. Predicted rms errors due to different sources (rotation, uncertainty of MK spectral type, photometric errors) were compared with the dispersion of the observed extinction data, and it was found that part of the large scatter could be due to intrinsic differences of the properties of interstellar grains. (auth)

58490 DETERMINATION OF NONLINEAR EFFECTS OF LIMB DARKENING IN ECLIPSING VARIABLES FROM OBSERVATIONS OF THEIR LIGHT MINIMA. Kopal, Zdenek (Univ. of Manchester, Eng.). Astrophys. Space Sci.; 12: No. 1, 147-50 (Jul 1971).

It is pointed out that observations of eclipsing variables within minima do not, in general, allow a separation of the quadratic terms of limb darkening from the first-order effects of the gravity darkening of distorted components undergoing eclipse. Only a difference of the two can be deduced from the observations, but—especially in close binaries—the net effect will be dominated by gravity darkening. (auth)

58491 EVOLUTION OF THE M31 DISK POPULATION. Tinsley, Beatrice M. (Univ. of Texas, Dallas); Spinrad, Hyron . Astrophys. Space Sci.; 12: No. 1, 118-36(Jul 1971).

An evolutionary model for the M31 inner disk population is described, which at age 12 billion years agrees closely with the narrow-band colors and line indices recently measured by Spinrad et al. (1971), and with the broad-band colors from 0.36 to 3.4 μ. Assuming that gE galaxies have the same stellar population as the M31 inner disk, this model is used to derive evolutionary effects in cosmology. Interpretation of the magnitude–redshift relation is substantially affected, since the evolutionary correction to V magnitudes at redshift 0.2 may be 0.09 mag. if $H_0 = 100$ km s^{-1} Mpc^{-1}, or ≥ 0.25 mag. if $H_0 = 50$. Changes in some line strengths may be observable at redshift 0.46, showing the younger stellar population at earlier times. The results differ from estimates by other authors, also based on the assumption that the gE and disk populations are identical, that the photometry of Spinrad et al. (1971) precludes a significant rate of evolution. One reason for the difference is that the model has an unexpectedly shallow luminosity function just below the main sequence turnoff; another reason is that authors in the past have used the change in absolute V magnitude as the evolutionary correction, whereas the appropriate quantity is the change in absolute magnitude at the emitted wavelengths, and evolution is more rapid at these shorter wavelengths. (auth)

58492 URCA PROCESS AT HIGH TEMPERATURES AND DENSITIES. McFee, R. W; Schlitt, D. W. (Univ. of Nebraska, Lincoln). Astrophys. Space Sci.; 12: No. 1, 4-9(Jul 1971).

The URCA neutrino loss rate from a hot stellar environment is investigated. The results indicate that the loss rates for URCA-type processes from even-mass-number nuclei are comparable to the rates from odd-mass-number nuclei at temperatures above about 10^9 K. Rates are calculated for some typical odd-mass isobar pairs and for the even-mass isobar fifty-six for temperatures between 5×10^8 K to 5×10^{10} K. (auth)

58493 NEUTRON STAR MODELS. Boerner, Gerhard (City Coll., New York); Sato, Katsuhiko. Astrophys. Space Sci.; 12: No. 1, 40-6(Jul 1971).

Neutron-star models are calculated using an equation of state discussed in an earlier paper. A maximum mass for a neutron star of 1.74 solar masses is found. The central density of the star is 3.3×10^{15} g/cm^3. The lightest stars have masses of 0.02 (resp. 0.03) solar masses with central densities 2.2×10^{14} g/cm^3 (resp. 1.9×10^{14}). (auth)

58494 STRUCTURE OF RAPIDLY ROTATING RELAXED GLOBULAR CLUSTERS. Kormendy, John; Anand, S.P.S. (Univ. of Toronto, Richmond Hill, Ont). Astrophys.Space Sci; 12: No.1, 47-57(Jul 1971).

A model of rapidly rotating globular clusters was constructed, assuming uniform angular velocity and a truncated Maxwellian distribution in the stellar velocities. Since the first-order theory developed by Woolley and Dickens becomes inaccurate for rapid rotation, a small-mass envelope was fitted to their models by the method of Monaghan and Roxburgh. A comparison was made of the critical values derived by the two methods. (auth)

58495 RAPIDLY ROTATING POLYTROPES IN POST-NEWTONIAN APPROXIMATION TO GENERAL RELATIVITY.

Fahlman, G. G.; Anand, S. P.S. (Univ. of Toronto). Astrophys. Space Sci.; 12: No. 1, 58-82(Jul 1971).

The study of uniformly rotating polytropes with axial symmetry was extended to include all rotational terms of order Ω^4, where Ω is the angular velocity, consistently within the first post-Newtonian approximation to general relativity. The equilibrium structure was determined by treating the effects of rotation and post-Newtonian gravitation as independent perturbations on the classical polytropic structure. The perturbation effects are characterized by a rotation parameter $v = \Omega^2/2\pi G\rho_c$ and a relativity parameter $\sigma = p_c/\rho_c C^2$, where p_c and ρ_c are the central pressure and density, respectively. The solution to the structural problem was obtained by following Chandrasekhar's series expansion technique and was complete to the post-Newtonian rotation terms of order σv^2. The critical rotation parameter v_c, which characterizes the configuration with maximum uniform rotation, was accurately evaluated as a function of σ. Numerical values for all the structural parameters needed to determine the equilibrium configurations are presented for polytropes with indices $n = 1$, 1.5, 2, 2.5, 3, and 3.5. (auth)

58496 RAPIDLY ROTATING SUPERMASSIVE STARS IN THE FIRST POST-NEWTONIAN APPROXIMATION TO GENERAL RELATIVITY. Fahlman, G. G; Ananad, S. P. S. (Univ. of Toronto). Astrophys. Space Sci.; 12: No. 1, 83-97(Jul 1971).

The structure and stability of rapidly uniformly rotating supermassive stars was investigated using the full post-Newtonian equations of hydrodynamics. The standard model of a supermassive star, a polytrope of index three, was adopted. All rotation terms up to and including those of order Ω^4, where Ω is the angular velocity, were retained. The effects of rotation and post-Newtonian gravitation on the classical configuration were explicitly evaluated and shown to be very small. The dynamical stability of the model was treated by using the binding energy approach. The most massive objects were found to be dynamically unstable when $\sigma = 1/c^2 \cdot p_c/\rho_c \gtrsim 2.2 \times 10^{-3}$, where p_c and ρ_c are the central pressure and density, respectively. Hence, the higher-order terms considered did not appreciably alter the previously known stability limits. The maximum mass that can be stabilized by uniform rotation in the hydrogen-burning phase was found to be 2.9×10^6 $M_\odot$, where $M_\odot$ is the solar mass. The corresponding nuclear-generated luminosity of $\sim 6 \times 10^{44}$ erg/sec^{-1} is too small for the model to be applicable to the quasi-stellar objects. The maximum kinetic energy of a uniformly rotating supermassive star was found to be 3×10^{-5} Mc^2, where M is the mass of the star. Masses in excess of 10^{10} $M_\odot$ are required if an adequate store of kinetic energy is to be made available to a pulsar like QSO. However such large masses have rotation periods in excess of 100 yr and thus could not account for any short term periodic variability. It was concluded that the uniformly rotating supermassive star does not provide a suitable base for a model of a QSO. (auth)

58497 POSSIBLE BLACK HOLE IN BETA LYRAE. Devinney, E. J. (Univ. of Florida, Tampa). Nature (London): 233: No. 5315, 110-12(10 Sep 1971).

It is stated that β-Lyrae is one of the most controversial and puzzling of binary systems. The central issue concerns the absolute masses of the two components. Although spectroscopy does not reveal the mass ratio of the components, the photometry of the system provides important information through the photometric effect of tidal and rotational distortion, and an attempt is made to use this effect to determine the mass ratio by fitting theoretical light curves to observations throughout the phase interval between eclipses. The calculations presented are adapted from a program for computing monochromatic complete light curves of close binaries in which all distortion and mutual irradiation effects are considered. Reasons are given as to why β-Lyrae is a most interesting exception in which the photometric technique can be applied to determination of the mass ratio. It is considered to be virtually certain that the secondary must be a very remarkable object, at least four magnitudes underluminous for its mass. The large value for its mass excludes the possibility of its being a white dwarf or neutron star, but it may be a "black hole", or perhaps some previously unknown stellar state. The importance of this system for understanding the nature of massive underluminous stars is considered to be great. (UK)

58498 BLACK HOLES AS AGENTS OF MAGNETIC FIELDS. Wald, R. M. (Princeton Univ., N. J.). Nature (London): 233: No. 5314, 52-3(3 Sep 1971).

It is contended that it is highly unlikely that the magnetic field of a "black hole" could ever be large enough to produce astrophysically observable effects. There is considerable evidence that the only electromagnetic field a "black hole" can have is the Kert Newman field, of which the magnetic dipole moment is a convenient strength indicator. Firm upper limits are obtained for such a field. (UK)

58499 ANALYTIC MODEL OF ECLIPSING BINARY STAR SYSTEMS. Wood, David B. (Bellcomm, Inc., Washington, D. C.). Astron. J.; 76: No. 8, 701-10(Oct 1971).

A new approach to the modeling of eclipsing binary star systems is described. The model takes advantage of a digital computer and thus allows a reduction in the number of simplifying assumptions and eliminates rectification altogether. The validity of this model is tested through analysis of numerical integration errors, comparison with the spherical model, parametric studies, and application to observational data. It is concluded that the model is a valid representation of eclipsing systems, and that it is a useful tool for the analysis of such systems. (auth)

58500 CATALOGUE OF CARBON STARS IN THE SOUTHERN MILKY WAY. Westerlund, B. E. (European Southern Observatory, Santiago de Chile). Astron. Astrophys., Suppl. Ser.; 4: No. 1, 51-74(Aug 1971).

An objective-prism survey in infrared light was carried out of the southern Milky Way from $l^{II} = 235°$ to $l^{II} = 7°$ and between $b^{II} = \pm 5°$. The present catalogue gives positions and estimated visual and infrared magnitudes for 1124 carbon stars identified in the survey. The positions of the stars will be given on overlays to an Atlas of the southern Milky Way, which is under preparation. (auth)

58501 WAVELENGTH SHIFTS OF INTENSITY MINIMA IN TYPE-I SUPERNOVA SPECTRA. Branch, D.; Patchett, B. (Royal Greenwich Observatory, Hailsham, Eng.). Nature (London) Phys. Sci.; 233: No. 37, 29-30(13 Sep 1971).

Attempts have been made to interpret Type-I supernova spectra as solid-state absorption bands superposed on continuous backgrounds, and bands of Fe ions in crystals such as garnet silicates or bands of metal atoms trapped in hydrocarbons have been implicated. It is pointed out, however, that such identifications, based on coincidences between laboratory wavelengths for the solid-state bands and measurements in published supernovae spectra, have not taken into account the fact that some features in Type-I spectra undergo substantial wavelength shifts (Minkowski, Astrophys. J., 89: 156(1939)). Such shifts were used to test the proposed identifications on the assumption that bands of common origin would show similar behavior. Wavelengths of intensity minima in spectra of IC 4182, NGC 4496, and NGC 1003 are shown graphically, and the spectra are discussed, particularly with reference to interstellar diffuse bands and identifications of the observed minima with the diffuse bands and with reference to wavelength shifts. An association between supernova features and diffuse bands was not entirely disproved, since the bands could originate in various kinds of grains, but such an hypothesis is made less attractive by the findings. (UK)

58502 Am STARS AS POSSIBLE MEMBERS OF TWO SUBGROUPS OF THE SCORPIUS–CENTAURUS ASSOCIATION. Glaspey, John W. (Univ. of Arizona, Tucson). Astrophys. J.; 169: No. 3, 525-7(1 Nov 1971).

Photometric evidence suggests that the Am star HD 148321 is not a member of the Upper Scorpius subgroup of the Scorpius–Centaurus association. An Am star in the Upper Centaurus subgroup, HD 119674, is a possible member. (auth)

58503 ENERGY DISTRIBUTIONS AND SPECTRA OF ORION B STARS. Schild, Rudolph E.; Chaffee, Frederic (Smithsonian Astrophysical Observatory, Cambridge, Mass.). Astrophys. J.; 169: No. 3, 529-36(1 Nov 1971).

New MK spectral types and energy distributions are presented for B stars in Orion for which far-ultraviolet flux excesses have recently been discovered. Significant differences between HD spectral types and the new MK types were found. Moreover, the energy distributions showed the Orion late B stars to have smaller Balmer discontinuities than do field stars of the same spectral types. For the late B stars, these effects cause the 1500 Å fluxes to be underestimated by approximately 0.5 mag. No comparable systematic effects were found for the early B stars. (auth)

58504 SPECTRUM OF LkHα-101 IN THE NEAR-INFRARED. Herbig, G. H. (Univ. of California, Santa Cruz). Astrophys. J.; 169: No. 3, 537-41(1 Nov 1971).

LkHα-101 is the $m_{pg} = 17$ star that appears to be the source of illumination of NGC 1579, and which has recently been found to be very bright in the infrared by Cohen and Woolf and by Kleinmann. In the near-infrared, the spectrum contains many narrow emission lines of H, O I, [O II], [Fe II], [Cr II], . . ., together with a

XUM

number of unidentified features that were found in η Car by Thackeray. The emission-line spectrum is quite unlike that of the T Tauri stars, or of VY CMa. The distance, inferred from UBV data for two B-type stars lying in the same dark cloud, is at least 800 pc. (auth)

58505 TWO YOUNG BRIGHT INFRARED OBJECTS. Cohen, Martin (Cambridge Univ., Eng. Univ. of Minnesota, Minneapolis); Woolf, N. J. Astrophys. J.; 169: No. 3, 543-7(1 Nov 1971).

Infrared photometric observations between 2μ and 22μ are reported for LkHα-101 and LkHα-190. LkHα-101 is currently the brightest infrared source known at the center of a cometary nebula. The spectral distribution is a broad peak resembling a blackbody of ~750°K but with excess emission to longer wavelengths, and depressed to shorter wavelengths. Lick Hα-190, a recently brightened object photometrically resembling the FU Ori phenomenon, is about 4 mag fainter than LkHα-101 at 3 to 5 μ, but is equally bright at 20 μ. The energy distribution from 2 to 5 μ is interpreted as a reddened continuum. A double-peaked structure at 10 and 20 μ is interpreted as a moderately thick silicate shell at ~110°K. (auth)

58506 SOME DOUBLE-LINED ECLIPSING BINARIES WITH METALLIC-LINE SPECTRA. Popper, Daniel M. (Univ. of California, Los Angeles). Astrophys. J.; 169: No. 3, 549-62 (1 Nov 1971).

Spectroscopic orbits were obtained for the metallic-line eclipsing binaries XY Cet, RR Lyn, and MY Cyg. Provisional orbits are also given for the A-type giant SZ Cen. In conjunction with available photometric results, these orbits lead to the properties of the components. These systems are shown in the (log m, log R)- and [(B − V), log g]-planes in two of the figures, along with systems previously discussed, β Aur, WW Aur, TX Her, CM Lac, V477 Cyg, and EI Cep. Sirius is included. The regions of metallicism in these planes are roughly delineated. The incidence of metallicism in some other eclipsing binaries of type A is discussed briefly. The membership of RR Lyn in the Ursa Major stream is shown to be unlikely, and that of β Aur questionable. (auth)

58507 OSCILLATIONS OF A MAGNETIC POLYTROPE. Trehan, S. K.; Billings, Dana F. (Univ. of Colorado, Boulder). Astrophys. J.; 169: No. 3, 567-84(1 Nov 1971).

The second-order-tensor virial formulation for gaseous configurations with a prevalent magnetic field is applied to determine the effect of a weak poloidal magnetic field on the fundamental modes of oscillations of a polytrope. The theory of polytropes with a poloidal magnetic field is reviewed and simplified. The various tensors, in terms of which the characteristic frequencies of oscillation are expressed, are evaluated correctly to first order in h (the ratio of the magnetic to the gravitational energies, apart from a numerical factor). It is found that of the nine modes of oscillation, three are neutral, four are nonradial, and two are the coupled radial and the nonradial modes. The results of the effect of a weak magnetic field ($h \ll 1$) on the various modes of oscillation are tabulated for polytropic indices n = 1, 1.5, 2, 3, 3.5, and 4. (auth)

58508 ELEMENT PRODUCTION IN SIMPLE HELIUM BURNING. Hansen, Carl J. (Univ. of Colorado, Boulder). Astrophys. J.; 169: No. 3, 585-8(1 Nov 1971).

The final abundances of the α-nuclei (^{12}C, ^{16}O, ^{20}Ne, etc.) resulting from helium burning at constant temperature and density were computed by using recently available reaction rates. For one density (10^5 g cm^{-3}) the calculation was extended up to a temperature high enough to demonstrate the emergence of the e-process. (auth)

58509 COLLISION BROADENING BY NEUTRAL HYDROGEN. Brueckner, Keith A. (Univ. of California, San Diego). Contract AT(11-1)-Gen-10. Astrophys. J.; 169: No. 3, 621-32(1 Nov 1971).

The theory of collision broadening by neutral hydrogen is summarized and given in simplified form. The error introduced by averaging over azimuthal quantum numbers is exhibited and shown to be small. The multipole expansion as usually used is shown to give very slow convergence. The exact expression is evaluated, avoiding the multipole expansion but using scaled hydrogenic functions, and is applied to the lines of Fe I. The predictions for the line width are considerably larger than the dipole−dipole estimate and are in reasonable agreement with the average broadening observed experimentally. (auth)

58510 RADIATIVE TRANSFER IN SPHERICALLY SYMMETRIC SYSTEMS. II. THE NON-CONSERVATIVE CASE AND LINEARLY POLARIZED RADIATION. Cassinelli, J. P.; Hummer, D. G. (National Bureau of Standards, Boulder, Colo. Univ. of Colorado, Boulder). Mon. Notic. Roy. Astron. Soc.; 154: No. 1, 9-21(1971).

The method for the solution of transfer problems in spherically symmetric systems developed recently by Hummer and Rybicki (Mon. Not. Roy. Astron. Soc., 152: 1(1971)) is generalized to the nonconservative case. This procedure, which depends on the iterative determination of the Eddington factor $f = K/J$, handles in a natural way the outward peaking of the radiation field which occurs in extended atmospheres. To illustrate the present extension of this method, solutions are obtained for the problem of scattering of linearly polarized radiation by an extended electron-scattering atmosphere. Although the transfer of radiation through such an atmosphere is conservative, each of the component equations is not. For opacity laws of the form $\kappa\rho = r^{-n}$, $o < r < R$, $n =$ 2 and 3, very large values of the polarization are found as a general feature arising from the strong peaking of the radiation field. It is found that the temperature distribution in such extended electron-scattering atmospheres differs negligibly from that computed on the assumption of isotropic scattering, with the neglect of polarization. The procedure used for the polarization problem can also be applied directly to problems with a nongrey opacity involving many frequencies simultaneously. (auth)

58511 EFFECTIVE TEMPERATURE, RADIUS, AND GRAVITATIONAL REDSHIFT OF SIRIUS B. Greenstein, J. L.; Oke, J. B.; Shipman, H. L. (California Inst. of Tech., Pasadena). Astrophys. J.; 169: No. 3, 563-6(1 Nov 1971).

Analysis of the Hα and Hγ line profiles in Sirius B, along with the apparent magnitude and parallax, yields $T_{eff} = 32000° \pm 1000°K$, $\log g = 8.65$, and $R/R_\odot = 0.0078 \pm 0.0002$. These values put Sirius B on the mass−radius relation for degenerate configuration of helium. The measured gravitational redshift is 89 ± 16 km s^{-1}, which is in excellent agreement with that predicted by the radius and gravity. (auth)

58512 SEARCH FOR INTERSTELLAR SILICATE ADSORPTION IN SPECTRUM OF VI CYG NO. 12. Stein, W. A.; Gillett, F. C. (Univ. of California, San Diego. Univ. of Minnesota, Minneapolis). Nature (London) Phys. Sci.; 233: No. 39, 72-3(27 Sep 1971).

The star VI Cyg No. 12 was examined up to 11 μm in an attempt to detect interstellar silicate absorption and to compare the results with those of others. A plot of the energy distribution is shown, from data obtained at the Kitt Peak National Observatory and from the UCSD-UM 60-inch telescope at Tucson, Arizona. No absorption at 11 μm that could be attributed to silicate-type material was observed and there was no evidence of excess at 11 μm that would be expected if silicate grains were close enough to the star to be heated by stellar radiation. Upper limits to the amount of absorbing materials in the line of sight to the star are estimated, including estimates for enstatite and olivine. It appears to be likely that a significant amount of the grain material in the line of sight consists of materials other than silicates, and uv observations have produced strong evidence in favor of interstellar graphite. (UK)

58513 EMISSION-LINE SPECTRUM OF THE ORION NEBULA IN THE WAVELENGTH RANGE 4959 TO 8665 A. Morgan, Lesley A. (California Inst. of Tech., Pasadena. Carnegie Institution of Washington, D. C.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 393-9(1971).

Among new lines identified were eight O I lines whose intensities cannot be accounted for by recombination. The [Cl IV] line λ7531 was seen for the first time; from its intensity it was found that the abundance of Cl^{3+} is small compared to that of Cl^{2+}. Using this result and the intensities of the [Cl III] lines given by Aller and Liller it was found that $N(Cl)/N(O^{2+}) \simeq 0.008$. (auth) (UK)

58514 CYGNUS LOOP AT 1420 MHz. Moffat, P. H. (Mullard Radio Astronomy Observatory, Cambridge, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 401-12(1971).

Part of the Cygnus Loop was mapped at 1420 MHz, using the Cambridge half-mile telescope with a resolution of $140'' \times 280''$. The source has a complex structure which is closely associated with that of the optical nebula. A high fractional polarization in the southern part of the source implies a magnetic field aligned parallel to a fairly well defined shell structure. The radio spectrum of the northeastern part of the source shows that the emission is nonthermal, but is not measurably polarized. The implications of the observations are discussed, with particular reference to van der Laan's theory of the radio emission and the possibility that the optical "filaments" are excited by the shock wave at the boundary of the supernova remnant. (auth) (UK)

58515 TIME VARIATIONS IN THE EMISSION LINES OF Of STARS. Brucato, Robert J. (Northwestern Univ., Evanston, Ill.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 435-52(1971).

Spectrograms covering the region between Hβ and Hγ at a reciprocal dispersion of 28 Å mm^{-1} were obtained for the Of stars HD 108, HD 188001 (9 Sge), HD 190429N, HD 192639, HD 210839 (λ Cep) and, at 42 Å mm^{-1}, for HD 66811 (ξ Pup). Equivalent widths were measured for several spectral features, particularly N III $\lambda\lambda$4634–40–41 and He II λ4686. The strengths of these lines are shown to vary in several of these stars with time scales of the order of 10 min, with the most striking changes occurring at λ4686 in the earliest spectral types. (auth) (UK)

58516 CALCULATIONS OF THE LEVEL POPULATIONS FOR THE LOW LEVELS OF HYDROGENIC IONS IN GASEOUS NEBULAE. Brocklehurst, M. (University Coll., London). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 471-90(1971).

The level populations, b_{nl}, of hydrogen and singly ionized helium are calculated making full allowance for collisional redistribution of angular momentum and energy. In many cases the l-states are not populated statistically. Intensities of the most important line series are presented for the principal quantum number $n \leq 40$ and for a wide range of electron temperatures and electron densities. Calculated relative intensities in the spectra of H I are compared with observed intensities in the planetary nebula NGC 7662. The agreement with the photoelectric observations is good, but there is poor agreement with the photographic observations. (auth) (UK)

58517 ENERGY DISTRIBUTIONS OF MAIN-SEQUENCE STARS. Stickland, David J. (Royal Greenwich Observatory, Hailsham, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 501-20(1971).

A wide range of MK standard main-sequence stars was observed with a spectrum scanner and spectral energy distributions derived. These were corrected, where necessary, for the effects of interstellar reddening and line blanketing. The flux curves so obtained were compared with the predictions of several recent sets of model stellar atmospheres through a scheme of parametrization in which the main characteristics of the curves are represented by a Balmer discontinuity parameter and three spectral gradients. While the general features are predicted, even the most sophisticated grids of models fail to reproduce the fine details of the energy curves for the whole range of spectral types. (auth) (UK)

58518 IMPORTANCE OF CIRCULATION IN RADIATIVE STELLAR ENVELOPES. Smith, R. Connon (Univ. of Sussex, Brighton, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 33P-5P(1971).

It is shown that a recently proposed rotation law (Marks and Clement, Astrophys. J., 166: L.27(1971)) cannot be relevant to many observed early-type stars. (auth) (UK)

58519 PHENOMENA OF FLUORESCENCE IN STARS. Swings, P. (Univ., Liege). Mem. Soc. Roy. Sci. Liege; 1: No. 2, 131-41(1971). (In French).

Some atomic rays and molecular bands appear in emission from various heavenly bodies; this emission is frequently due to a fluorescence mechanism. Several examples of experimental studies are described. The following astronomical phenomena are then discussed: (1) presence of lines from In, Ga, Sc, and Ti in long-period variable stars; (2) presence of unresolved multiplets of Fe I in variable cold stars; (3) emission lines of Mn I, excited by λ2794 and λ2801 of Mg II in variable cold stars; (4) atomic and molecular emissions produced by photodissociation, photochemical luminescence, and induced predissociation; (5) the Bowen mechanism; (6) the possibility of the transition n = 4 to n = 3 in He II with an emission of λ4686; (7) selectivity among the emission lines of He I, O I, C III, N IV, Si III, Si II, Fe II, N II, C II, H, etc., in hot stars; and (8) the possibility of fluorescence phenomena in the ultraviolet region of symbiotic stars, of variable to long-period stars, and of comets. (tr-auth)

58520 EXTREME REGIMES OF TEMPERATURE AND PRESSURE IN ASTROPHYSICS. Ruderman, Malvin A. (Columbia Univ., New York). Pure Appl. Chem.; 22: No. 3-4, 429-47(1970).

From International conference on thermodynamics; Cardiff, Wales (1 Apr 1970).

States of matter and phenomena in extreme régimes of temperature and density found in the Universe are surveyed: thermodynamics and stellar evolution, terminal states of stars, temperatures of stars, forms of superdense matter in stars, crystallization of superdense stellar matter, neutron star structure, and low temperature phenomena in neutron stars. (auth) (UK)

58521 THERMODYNAMICS OF HYPERON STARS. Koebke, K.; Hilf, E. (Univ., Wuerzburg, Ger.). Pure Appl. Chem.; 22: No. 3-4, 469-80(1970).

From International conference on thermodynamics; Cardiff, Wales (1 Apr 1970).

For a single-component perfect Fermi gas, the numerical program for the equation of state given by Bauer was used. For a star of hot nondegenerate neutron gas, the deviations of the internal structure with regard to a totally degenerate neutron star were calculated. For a multi-component perfect gas with an exponential-type elementary particle spectrum the equation of state is given. The highest possible temperature is $T_0 = 2 \times 10^{12}$°K, where the total mass density diverges. For the central region of hyperon stars, in contrast to previous work, it can be proved that the time component of the metric tensor has no singularity, and that the velocity of sound tends to zero (instead of rising above the velocity of light). (auth) (UK)

Quasi-Stellar, Radio, and X-Ray Sources

Refer also to abstract 58700.

58522 (CSIRO-Trans–10649) SLOW VARIATIONS OF PULSAR RADIO EMISSION. Erukhimov, L. M. Translated by G. Losonci (Commonwealth Scientific and Industrial Research Organization), from Astron. Tsirk.; No. 513, 3-5(1969). 3p. Dep. NTIS (U. S. Sales Only).

It is shown that the dependence of time scale on the total column of electrons and velocity of the source is made clear by taking into account the minute variations of large inhomogeneities ($l_0 \sim 10^{13}$ cm), which may be responsible for the observed variations in pulsar emission of $\tau \sim 10^5$ to 10^6 sec. (Australia)

58523 (CSIRO-Trans–10650) QUASARS: PRECLUSTERS OF GALAXIES. Vorontsov-Velyaminov, B. A. Translated by G. Losonci for Australian Atomic Energy Commission Research Establishment, Lucas Heights from Astron. Tsirk.; No. 513, 5-7 (1969). 5p. Dep. NTIS (U. S. Sales Only).

An hypothesis is suggested, according to which quasi-stellar galaxies (quasags) produce radio emission from time to time, turning into quasars and readily disintegrating at this stage. Further chain fragmentation of quasags (solar masses 10^9 to 10^{13}) leads to formation of galaxy groups or clusters retaining the ability of nonthermal recurrent radio emission. The radio emission of dwarfs is therefore an elimination process. Identical forms with and without radio emission corresponding to fragmentation stages of initial objects in the metagalaxy are listed. (Australia)

58524 RADIO INTENSITY VARIATIONS OF 3C 273 AT 2.3 AND 8.15 mm. Efanov, V. A.; Kislyakov, A. G.; Moiseev, I. G.; Naumov, A. I. (Crimean Astrophysical Observatory, Moscow. Gorky State Univ., USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 338-9(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 435-6(Mar-Apr 1971).

The radio flux density of 3C 273 was observed with the 22-m radio telescope of the Crimean Astrophysical Observatory. Comparisons with Jupiter yielded values (in late June, 1969) of $(51 \pm 3) \times 10^{-26}\ W \cdot m^{-2} \cdot Hz^{-1}$ at $\lambda = 8.15$ mm, and $(66 \pm 17) \times 10^{-26}\ W \cdot m^{-2} \cdot Hz^{-1}$ at $\lambda = 2.3$ mm. The spectral index of the source over the range 2 to 8 mm was therefore $\alpha = 0.15 \pm 0.25$. From May 1968 to June 1969 the flux density of the source decreased at both 8.15 mm and 2.3 mm, while the spectral index decreased from 0.4 ± 0.15 to 0.15 ± 0.25. The measurements of 3C 273 at $\lambda = 8.15$ mm are compared with other reports of the radio intensity of this source at nearby wavelengths. (auth)

58525 ABSOLUTE MEASUREMENTS OF THE RADIO INTENSITY OF VIRGO A IN THE 10 TO 30-cm RANGE. Dmitrenko, D. A.; Dmitrenko, L. V.; Ivanov, O. S.; Tseitlin, N. M. (Gorky State Univ., USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 340-1(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 437-8(Mar-Apr 1971).

Absolute measurements of the radio flux density of Virgo A at wavelengths of 10, 13, 15, 20, 23, 25, 27, and 30 cm were made to 5 to 7% accuracy by comparison with the radiation of a "black" disk located in a Fresnel zone of a 7-m radio-telescope antenna. The spectral index for this wavelength range is 0.76 ± 0.1. (auth)

58526 POSSIBLE ANTENNA MECHANISM FOR COSMIC RADIO EMISSION. Kaplan, S. A.; Eidman, V. Ya. (Gorky State Univ., USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 344-6(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 440-3(Mar-Apr 1971).

It is shown that intensive coherent generation of radio waves is

XUM

possible in neutral electric-field regions within powerful radio sources. (auth)

58527 INDUCED COMPTON SCATTERING BY THERMAL ELECTRONS AND THE LOW-FREQUENCY SPECTRUM OF RADIO SOURCES. Syunyaev, R. A. (Inst. of Applied Mathematics, Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 190-6(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 244-52(Mar-Apr 1971).

Induced Compton scattering by thermal electrons should produce characteristic distortions in the low-frequency radiation spectrum of radio sources if the radiation brightness temperature exceeds $kT_b = m_e c^2/\tau_T (1 + \tau_T)$. Even if the source has a small optical depth for Thomson scattering ($\tau_T \ll 1$), the conclusions remain valid. They are also independent of the electron temperature. If its spectrum is free from distortion, an upper limit can be set on the thermal-electron density in a compact radio source. (auth)

58528 IONIZED-HYDROGEN DISTRIBUTION IN THE GALAXY. Ariskin, V. I. (Lebedev Inst. of Physics, Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 197-202(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 253-9(Mar-Apr 1971).

An analysis of moderate-resolution ($\approx 40'$) galactic surveys in the H I line and in the continuum indicates that the Galaxy contains a number of large-scale H II regions, the main factor responsible for the thermal background radio emission. Some of these regions are spatially related to discrete sources of excited-hydrogen radio lines. The correlation increases if the individual compact H II zones are assumed to have peculiar radial velocities of ≈15 to 30 km/sec. (auth)

58529 LUNAR OCCULTATIONS OF RADIO SOURCES AS A TECHNIQUE FOR INVESTIGATING THEIR ANGULAR STRUCTURE. Abramyan, G. L. (Gorky State Univ., USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 210-13(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 269-74(Mar-Apr 1971).

A solution is given for the problem of determining the angular structure of a radio source from observations of its occultation by the Moon in a narrow frequency band with a large signal/noise ratio. The method developed is subjected to a numerical computer test simulating observational data. (auth)

58530 IDENTIFICATION OF COSMIC X-RAY SOURCES. Amnuel, P. R.; Guseinov, O. Kh. (Shemakha Astrophysical Observatory, Baku). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 218-24(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 280-7(Mar-Apr 1971).

The correlation is examined between discrete galactic x-ray sources and dark nebulae, H II regions, close binary stars, Wolf-Rayet stars, planetary nebulae, novae, and flare stars. An effort is made to obtain specific identifications. No correlation is found between these objects and the x-ray sources; in many cases no such object falls within the error box for the position of a given source. Evidently x-ray sources do not comprise a homogeneous group of objects; some of them might be relativistic stars undergoing accretion. (auth)

58531 GREEN BANK SKY SURVEY IN SEARCH OF RADIO SOURCES AT 1400 MHz. I. A SPECTRAL ANALYSIS OF THE 5C1 SOURCES. Maslowski, J. (National Radio Astronomy Observatory, Green Bank, W. Va.). Astron. Astrophys.; 14: No. 2, 215-22(Sep 1971).

The NRAO 300-foot telescope was used to make a survey of the sky at 1400 MHz in a 6° strip of declination between $+45.8$ and $+51.7°$ and between right ascension 7h17m and 16h23m. A map of the full survey and a brief description of the observations and the reduction procedure are given. The region of the survey that overlapped the 5C1 survey is also briefly discussed. A limiting flux density $S = 0.09 \times 10^{-26}$ W m^{-2} Hz^{-1} of the survey was reached. (auth)

58532 POLARIZATION AND THE MAGNETIC FIELD SCALE IN RADIO SOURCES. Perola, G. C. (Univ., Milan). Astron. Astrophys.; 14: No. 2, 337-9(Sep 1971).

A statistical analysis of the intensity of the polarized radiation may help to determine the scale of the magnetic field in the extragalactic extended radio sources. (auth)

58533 X- AND γ-RAY ASTRONOMY BETWEEN 1962 AND 1970. Koch, L. (CEN de Saclay, Gif-sur-Yvette, France). Rech. Spatial.; 10: No. 3, 10-13(May 1971). (In French).

The principal results obtained in x- and γ-ray astronomy between 1962 and 1970 are presented. The sky background, the various x-ray sources (blue stars, nebulas, extragalactic objects) and γ-ray sources (the Crab and the galactic center) are considered. (France)

58534 EVIDENCE FOR A HIGHLY COMPACT X-RAY SOURCE. Margon, Bruce; Bowyer, Stuart; Lampton, Michael; Cruddace, Ray (Univ. of California, Berkeley). Astrophys. J.; 169: No. 2, L45-8(15 Oct 1971).

A detailed spectrum of the x-ray source GX 340 + 0 is presented. The spectrum may be fitted from 1 to 10 keV by a blackbody model at $T = 1.5 \times 10^7$ °K, subject to heavy photoelectric absorption. Unlike x-ray sources previously reported, the spectrum is not also compatible with power-law or thermal-bremsstrahlung models. If the source is a blackbody at the distance indicated by its x-ray absorption, its radius is 8 km and luminosity 3×10^{37} ergs s^{-1}. This source may provide direct evidence for the existence of a neutron star. (auth)

58535 CORRELATED TRANSIENT SHORT-PERIOD OSCILLATION IN THE OPTICAL AND X-RAY FLUX FROM SCORPIUS X-1. Kestenbaum, H. (Columbia Univ., New York); Angel, J. R. P.; Novick, R.; Cocke, W. J. Astrophys. J.; 169: No. 2, L49-55(15 Oct 1971).

Correlated oscillations with a 20-s period were detected in a simultaneous observation of the x-ray and optical flux from Sco X-1. The oscillations persist for about 2 minutes and have amplitudes of (0.81 ± 0.17) and (0.56 ± 0.17) percent in the x-ray and optical bands, respectively. (auth)

58536 EVIDENCE OF HIGH-FREQUENCY OSCILLATIONS IN THE X-RAY FLUX FROM SCORPIUS X-1. Angel, J. R. P.; Kestenbaum, H.; Novick, R. (Columbia Univ., New York). Astrophys. J.; 169: No. 2, L57-61(15 Oct 1971).

An analysis of the x-ray flux from Sco X-1 taken over a 4-minute period shows evidence for oscillations in the frequency range 1 to 10 Hz which persist for typically 1 minute. (auth)

58537 POSITIONAL DETERMINATION OF NP 0532. McNamara, Bernard J. (Univ. of California, Santa Cruz). Publ. Astron. Soc. Pac.; 83: No. 494, 490-1(Aug 1971).

A newly determined position, based on recent observational data, is given for the pulsar NP 0532 (Crab nebula). (auth)

58538 LUNAR OCCULTATION OBSERVATIONS OF 25 RADIO SOURCES MADE WITH THE OOTY RADIO TELESCOPE: LIST I. Swarup, G.; Kapahi, V. K.; Sarma, N. V. G.; (and others) (Tata Inst. of Fundamental Research, Bombay). Astrophys. Lett.; 9: No. 2, 53-9(Sep 1971).

A survey of radio sources by the method of lunar occultation is being carried out at Ootacamund in India with a large steerable telescope whose collecting area is 8700 m^2. Results for 25 weak radio sources with flux densities lying in the range 0.4 to 4 fu at 327 MHz are presented. Seven sources have clear double components with separations ranging from 2.5 to 20 arc sec. Optical identifications are suggested for 8 of the 25 sources, 5 of which are possibly QSOs. The unidentified radio sources seem to be galaxies with high redshifts. (auth)

58539 VERY BLUE STELLAR OBJECTS APPEARING NEAR GALAXIES. Weedman, Daniel W. (Vanderbilt Univ., Nashville). Astrophys. Lett.; 9: No. 2, 49-51(Sep 1971).

Because of Arp's discovery that the quasar Markarian 205 is connected to the spiral galaxy NGC 4319, the entire Palomar Observatory Sky Survey was searched for very blue stellar objects appearing in or near galaxies. Nine such objects were found, and finding charts are given for these. (auth)

58540 INTERSTELLAR SCATTERING AND THE LOW-FREQUENCY SPECTRUM OF PSR 0833-45. Higgins, C. S.; Komesaroff, M. M.; Slee, O. B. (CSIRO, Sydney). Astrophys. Lett.; 9: No. 2, 75-6(Sep 1971).

A small diameter radio source was detected at 80 MHz in the direction of PSR 0833−45. The measured flux of 12 ± 2 fu was consistent with the source being the "smeared out" low frequency radiation from the pulsar. This supports the view of Ables et al. (1970) that the spectral turnover in the pulsed component of the emission at higher frequencies is the result of radiation scattering. (auth)

58541 MEASUREMENT OF THE 10-μm FLUX FROM THE CRAB NEBULA. Aitken, D. K.; Polden, P. G. (Univ. Coll., London). Nature (London) Phys. Sci.; 233: No. 38, 45-6(20 Sep 1971).

Observations of the Crab Nebula during Jan. and Feb. 1971 are reported at an effective wavelength of 10μm using a 4 arcmin beam on the 24 inch reflecting telescope at the University of London Observatory, and employing a Ga-doped Ge bolometer cooled to 1.8K as detector, together with a CaF$_2$ filter to reduce sky noise and a three beam photometer to reduce the effect of sky emission fluctuations and gradients. Results are shown in tabular and graphical form. The average flux was found to be 170 ± 50 FU at 10μm, significantly in excess of the value 30FU expected for a synchrotron model. Possible reasons for such an excess are discussed. (UK)

58542 SEARCH FOR PULSED GAMMA RAY EMISSION ABOVE 50 MeV FROM NP 0532. Vasseur, J. (CEN, Saclay, France). Nature (London) Phys. Sci.; 233: No. 38, 46-8(20 Sep 1971).

Observations are reported from a series of balloon flights, carrying a telescope sensitive to γ rays > 50 MeV, carried out during 1969 in southern France, and employing a 13-plate optical spark chamber, triggered by a Cherenkov detector scintillator coincidental system. The technique and analytical methods used are described in detail, and results are shown in tabular and graphical form. No definite conclusions regarding pulsed γ emission were obtained, except for an upper limit for such emission. (UK)

58543 LINE FORMATION IN PULSATING VARIABLE STARS. Kalkofen, W.; Whitney, C. A. (Smithsonian Astrophysical Observatory, Cambridge, Mass. Harvard Coll. Observatory, Cambridge, Mass.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 531-43(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

An integral equation method is described that solves the equation of radiative transfer in a spectral line for an opacity that depends on depth, frequency, and angle, and an expression is derived for the line source function of a two-level atom in a gas that is traversed by a plane, steady shock wave. The simultaneous equations for the transfer of radiation in a line and for the gas flow through a shock front are solved and cases that are indicative of the line formation in variable stars such as W Virginis, are discussed. (auth) (UK)

58544 SURVEY OF MICROWAVE RADIATION FROM PLANETARY NEBULAE. Higgs, L. A. (National Research Council, Ottawa). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 315-36(1971).

Radio observations of 121 planetary nebulae were made at wavelengths of 9.3, 4.5, and 2.8 cm, using the 46-metre telescope at the Algonquin Radio Observatory. Detectable radio emission was found for approximately one half of these nebulae. Flux densities (or upper limits to flux densities) were determined with an accuracy of the order of 0.04 flux units. It is hoped that this body of data will be of use for the study of radio spectra of planetary nebulae. (auth) (UK)

58545 CHARACTERISTICS OF THE RADIO PULSES FROM THE PULSARS. Lyne, A. G.; Smith, F. G.; Graham, D. A. (Univ. of Manchester, Jodrell Bank, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 337-82(1971).

The shape and structure of radio pulses from the majority of the pulsars were studied at frequencies of 151, 240, 408, and 610 MHz, using polarimeter receivers. Individual pulses from the stronger pulsars were recorded photographically. The integrated pulse profiles were obtained from on-line integration of the four Stokes parameters. Many of the results are presented graphically; the main characteristics are collected in a table. A discussion of the pulse widths and the change of polarization angle within the pulses supports the view that the integrated pulse profile represents a longitude distribution of emission, while the individual pulses represent individual beams of radiation. The changes of position angle within the profile suggest that the magnetic field has a simple configuration in the emitting region, and that it may resemble the equatorial part of a dipole field. New measurements of the rotation measures of five pulsars are presented together with a compilation of nine previous results. Some new measurements of period and position are also presented. (auth) (UK)

58546 OBSERVATIONAL EVIDENCE FOR STARK BROADENING IN RADIO RECOMBINATION LINES. Churchwell, E. (Max-Planck Institut fuer Radioastronomie, Bonn). Astron. Astrophys.; 15: No. 1, 90-4(Nov 1971).

Observations of the H109α and adjacent higher-order lines (H137β, H157γ, and H172δ) from Orion A and M17 indicate successively increasing line widths with increasing order. Since the telescope beamwidth, optical depth, and Doppler width are essentially the same for each line the excess broadening with increasing order is interpreted in terms of Stark broadening. It is concluded that Stark broadening does occur in the radio recombination lines emitted from Orion A and M17. The functional dependence of this broadening on the principal quantum number appears to follow an n^4 law as predicted by Griem (1967), however, evidence is given which indicates that the magnitude of Stark broadening has been over-estimated by Griem. (auth)

58547 DEGREE OF CIRCULAR POLARIZATION OF SYNCHROTRON RADIATION. Melrose, D. B. (Australian National Univ., Canberra). Astrophys. Space Sci.; 12: No. 1, 172-92 (Jul 1971).

Formulas describing synchrotron radiation were extended to include the effect of the presence of an ambient medium and the effect of reabsorption and Faraday rotation on the degree of circular polarization. Results were: (1) onset of Razin–Tsytovich suppression has no significant effect on the degree of circular polarization; (2) onset of self-absorption in a source subject to weak Faraday rotation (negligible Faraday rotation in an absorption length) causes the degree of circular polarization to reverse its sign and to decrease (by between one half and one quarter for typical parameters) in magnitude, and (3) as in (2) but for strong Faraday rotation (many rotations of the plane of polarization in an absorption length) the degree of circular polarization also reverses its sign and becomes slightly smaller in magnitude than for weak Faraday rotation. The transfer equation including the effects of the polarization is discussed in detail. (auth)

58548 OBSERVATION OF COSMIC SOFT X RAYS. Hayakawa, S. (Nagoya Univ., Japan); Kato, T.; Makino, F.; (and others). Astrophys. Space Sci.; 12: No. 1, 104-17(Jul 1971).

Cosmic soft x rays in the energy range between 0.14 and 7 keV were observed with thin polypropylene window proportional counters on board a sounding rocket. The field of view crossed the galactic plane in the Cygnus–Cassiopeia region at a large angle and reached the galactic latitudes of –55° and +30°. Referring also to the result with Be window counters, the energy spectrum of Cyg XR-2, the flux from the Cas A region, and the distribution of the intensity of diffuse x rays over the scanned region were obtained. The turnover of the Cyg XR-2 spectrum at about 1 keV indicated that the distance of the Cyg XR-2 source lies between 600 and 800 pc, if the turn-over is due entirely to interstellar absorption. The flux from the Cas A region was obtained as 0.23 ± 0.05 photons cm^{-2} sec^{-1} in the energy range between 1.1 and 4.1 keV. The intensity of diffuse soft x rays depends on the galactic latitude more weakly than expected from the interstellar absorption of extragalactic x rays and shows asymmetry with respect to the galactic equator, thus suggesting a contribution of galactic x rays. The spectrum of extragalactic x rays is approximately represented by a power law $E^{-1.8}$. (auth)

58549 PULSAR RADIO EMISSION FROM EXPANDING CHARGE SHEETS. Tademaru, E. (National Radio Astronomy Observatory, Green Bank, W. Va.). Astrophys. Space Sci; 12: No.1, 193-203(Jul 1971).

The distribution of energy in frequency and angle emitted from a sheet of charges that are moving out relativistically along dipolar magnetic field lines originating near the magnetic polar caps of a rotating neutron star was calculated. The angular distribution is conical with the angle of maximum intensity varying with frequency ω as $\omega^{-1/3}$ for $\omega \lesssim \omega_c \approx 2c/(R\theta_M{}^2)$, where $R\theta_M$ is the initial angular radius of the charge sheet at the surface of the star of radius R. At higher frequencies the width of the angular cone remains constant. The radiation is linearly polarized with the polarization vector in the plane of the line of sight and the magnetic axis. A sheet of uniform charge density and finite thickness has a frequency spectrum that varies from $\omega^{-2/3}$ to ω^{-4} for $\omega \lesssim \omega_c$ and $\omega \lesssim \omega_c$, respectively. These features are in good general agreement with the observed characteristics of the intensity, pulse shape, and frequency spectrum of the radio pulses from pulsars. (auth)

58550 TRANSIENT GAMMA-RAY SOURCES. Apparao, Krishna M. V.; Rengarajan, T. N. (Tata Inst. of Fundamental Research, Bombay). Proc. Indian Acad. Sci., Sect. A; 73: No. 5, 257-60(May 1971).

Gamma-ray production by particles escaping from a pulsar into the surrounding nebula is considered. The gamma-ray emission decreases with time and such pulsar–nebula complexes will be observed as transient sources. (auth)

58551 OBSERVATIONS OF PULSAR POLARIZATION AT 410 AND 1665 MHz. Manchester, R. N. (National Radio Astronomy Observatory, Green Bank, W. Va. Astrophys. J., S Suppl. Ser.; 23: No. 199, 283-319(Sep 1971).

Linear-polarization parameters and mean pulse profiles with good time resolution were determined for twenty-one pulsars, with comparable data at two frequencies, 410 and 1665 MHz, for most of these. In addition, circular polarization was measured at 410 MHz for about two-thirds of the pulsars discussed. The observations show that the fractional linear polarization varies over a wide range and that the amount of polarization is generally less at 1665 MHz than at 410 MHz. Circular polarization is generally weak. However, when it does occur, it frequently reaches a peak at the center of the pulse. In those pulsars where the linear polarization is not very weak, the variation in position angle is continuous through the pulse and the same at the two frequencies. Comparison of the total-intensity profiles for a given pulsar shows that pulse components can almost always be identified at the two frequencies, but they generally have different spectral indices. The observations give strong support to the pulsar model in which the radiation originates close to the surface of the star. Depolarization effects occurring in the pulsar magnetosphere are proposed to account for the variation in fractional polarization. (auth)

58552 MODEL FOR CENTAURUS X-3. Gribbin, J. (Cambridge Univ., Eng.). Nature (London) Phys. Sci.; 233: No. 36, 18-19(6 Sep 1971).

It is stated that the discovery of periodic variations in the x-ray flux from Cen X-3 prompted reconsideration of the model of white-dwarf pulsations, which was found inadequate to explain the clock mechanism in pulsars (see Astrophys. J. Lett., 167: L.87(1971)). From the discussion it is concluded that the basic mechanism operating in Cen X-3 and the presence of periodic variations with periods of a few seconds are compatible, at least qualitatively, with the excitation of radial vibrations in an underlying white-dwarf star by the return of matter ejected in some earlier violent event. Such a model also provides a ready explanation for fluctuations in the periods found by other workers, which could be related to changes in the properties of the star caused by the impingement of gas streams and, in particular, changes in the angular momentum of the star would have a direct effort on the pulsation periods. (UK)

58553 ECLIPSING BINARY MODEL OF CYGNUS XR-1. Dolan, J. F. (Case Western Reserve Univ., Cleveland). Nature (London); 233: No. 5315, 109-10(10 Sep 1971).

Reference is made to Agrawal (Nature, 232: 38(1971)), who described interesting observations of the variable x-ray source Cyg XR-1 at energies >20 keV, and it is pointed out that these observations may be consistently interpreted in terms of the eclipsing binary model for the source originally outlined by Dolan (Space Sci. Rev., 10: 830(1970)). It is possible to interpret the observations as being caused by immersion of the blackbody source behind its non-x-radiating companion. The observations were consistent with the random arrival of photons from a nonvarying source, which in the eclipsing binary model would be identified with the x-radiating plasma surrounding the system. The relevance of some other observations made subsequent to those of Agrawal is also discussed, and it is considered that the eclipsing binary model for the variability of Cyg XR-1 seems consistent with all observations to date. (UK)

58554 OPTICAL IDENTIFICATION OF CYGNUS X-1. Murdin, P.; Webster, B. L. (Royal Greenwich Observatory, Hailsham, Eng.). Nature (London); 233: No. 5315, 110(10 Sep 1971).

It is stated that the star HD 226868 is coincident, within a 3" error, with a faint and possibly variable radio source that itself is coincident, though with a large uncertainty, with the pulsating x-ray star Cyg X-1. Information about HD 226868 obtained from the literature is summarized, together with that obtained from spectrograms taken at the Royal Greenwich Observatory with the 98-inch telescope in July to August 1971, covering the range 3600 to 5200 Å. The star appears to be a normal B0 Ib supergiant, and its distance 2.0 kpc. If the coincidence of position between the Cyg X-1 source, the radio star, and the supergiant is too strong to be by chance, the x-ray source may be a companion to the supergiant, rather than identical with it. (UK)

58555 COMPACT RADIO SOURCES IN THE GALACTIC NUCLEUS. Downes, D.; Martin, A. H. M. (Cavendish Lab., Cambridge, Eng.). Nature (London); 233: No. 5315, 112-14 (10 Sep 1971).

New observations of Sgr A, the source identified with the galactic center, are described. These observations were made in January to March 1971, with the Cambridge 1-mile telescope at 2.7 and 5 GHz, and they suggest a three-component model; they also confirmed the existence of radio structure on a scale of 10 arcsec. The relation of these compact radio sources to the infrared emission is also discussed. The maximum baseline of the observations was 25,000 λ at 5 GHz. Curves are shown for fringe amplitude and phase and for brightness distributions. Interpretations are made of the radio spectra of the components. It is suggested that Sgr A be monitored for interplanetary scintillation, which might reveal even smaller radio components. (UK)

58556 EVOLUTION AT 8 GHz OF THE LINEAR POLARIZATION OF 3C 279. Aller, Hugh D.; Olsen, Edward T. (Univ. of Michigan, Ann Arbor). Astron. J.; 76: No. 8, 671-6(Oct 1971).

The linear polarization of 3C 279 has been monitored at 8 GHz since 1965. During the single extended outburst in flux density since that time, the plane of polarization of the variable components rotated by about 100° and is now nearly parallel to the direction of the line through the centers of the two source components found by recent very long-baseline-interferometer measurements. The apparent evolution in the magnetic field structure of the emitting regions indicates that the outward moving variable components are colliding with an ambient medium. The irregular effects of this medium may account for the short-term fluctuations in the flux density since 1968. (auth)

58557 APERTURE-SYNTHESIS OBSERVATIONS OF M17 AND W49A AT 2.695 GHz. Webster, William J. Jr.; Altenhoff, Wilhelm J.; Wink, Joern E. (National Radio Astronomy Observatory, Green Bank, W. Va.). Astron. J.; 76: No. 8, 677-82(Oct 1971).

The Omega Nebula (M17) and the thermal component of W49 (3C 398) were mapped with high resolution at 2.695 GHz. W49A was resolved into a clustering of components near the radio peak position, a component 2 arc min southeast of the peak position and a pair of components 1 arc min southwest of the peak position, while M17 consists of a broad component with a pair of small components superimposed. It is shown that the components in W49A are of high apparent excitation and contain a large mass of ionized hydrogen while the components of M17 are comparable with components of more normal H II regions like W3. It may be that W49A surrounds a young OB association. (auth)

58558 IDENTIFICATION OF RADIO SOURCES FROM THE OHIO SURVEY. Radivich, Mirjana M.; Kraus, John D. (Ohio State Univ., Columbus). Astron. J.; 76: No. 8, 683-5(Oct 1971).

Tentative identifications were made for 50 Ohio survey sources, many of which have flat or unusual radio spectra. About 40% of the identifications were with galaxies, 50% with stellar objects, and the remaining 10% were blank fields. (auth)

58559 CRAB NEBULA PULSAR RADIO PULSE ARRIVAL TIMES AT ARECIBO OBSERVATORY. Rankin, J. M. (Univ. of Iowa, Iowa City); Counselman III, C. C.; Richards, D. W. Astron. J.; 76: No. 8, 686-90(Oct 1971).

U.T.C. times of reception at Arecibo Observatory of 430-MHz radio pulses from the Crab Nebula pulsar are tabulated at approximately 3-day intervals from May 10, 1969 to April 6, 1971. Some arrival times recorded at various frequencies prior to May 1969 are also given. (auth)

58560 EXCITATION TEMPERATURES OF THE 18-CENTIMETER OH TRANSITIONS IN AN ABSORBING CLOUD. Manchester, R. N.; Gordon, M. A. (National Radio Astronomy Observatory, Green Bank, W. Va.). Astrophys. J.; 169: No. 3, 507-14(1 Nov 1971).

Observations at the 18-cm OH transition frequencies were made on, and adjacent to, the strong absorption source W12. The on-source observations show that the line ratios do not vary significantly across the main 9.5 km s^{-1} feature, and they thus imply that the excitation temperatures are approximately constant. This result also shows that the OH is clumped and that the velocity dispersion observed arises from bulk motion of the clumps. In the weaker absorption between 10 and 13 km s^{-1} the excitation temperatures depart greatly from thermodynamic equilibrium and are a strong function of radial velocity. Weak, apparently normal, emission was observed both north and south of the continuum source. Part of this emission appears to originate in the same OH cloud which produces the main absorption feature. With the assumption that the properties of the OH cloud are the same at the on-source and off-source positions, this observation enables the excitation temperatures for each of the transitions to be calculated. The results show that for the OH in the strong absorption feature, all four excitation temperatures are close to the background-radiation temperature. The implications of this result are discussed, and it is concluded that the OH is most probably imbedded in a dense H I region having a kinetic temperature of 5°K or less. Optical depths, projected density, and filling factor of the OH cloud are also calculated. (auth)

58561 X RAYS FROM PUPPIS A AND THE VICINITY OF VELA X. Seward, F. D.; Burginyon, G. A.; Grader, R. J.; (and others) (Univ. of California, Livermore). Astrophys. J.; 169: No. 3, 515-24(1 Nov 1971).

A new rocket observation of the Vela region confirmed that Vel X and Pup A are strong sources of soft x rays. X rays from

Vel X come from a broad region of sky with a diameter of ≈5°. This region is centered neither on the Vel X radio source nor on the pulsar. Optical filaments lie along one edge of the x ray-emitting region. X-ray spectra were derived for Vel X and Pup A. Neither source was detectable above ~2 keV. (auth)

58562 MICROSECOND INTENSITY VARIATIONS IN THE RADIO EMISSIONS FROM CP 0950. Hankins, T. H. (Univ. of California, San Diego). Astrophys. J.; 169: No. 3, 487-94 (1 Nov 1971).

A technique for the removal of the effect of dispersion by the interstellar medium from the radio emission from pulsars was developed. Observations of the pulsar CP 0950 over a bandwidth of 125 kHz at 111.5 MHz revealed time structure as short as the reciprocal bandwidth limit of 8 microseconds. Occasional isolated subpulses of 40,000 flux units were observed. (auth)

58563 RADIOFREQUENCY DETECTION OF AN ANOMALOUS INTERSTELLAR RECOMBINATION LINE. Chaisson, Eric J.; Ball, John A. (Harvard Coll. Observatory, Cambridge, Mass.). Astrophys. J.; 169: No. 3, 495-501(1 Nov 1971).

An anomalous microwave emission line discovered in the 94α spectrum toward W49 A and independently observed at 85α is shown to be the result of electronic recombination. This paper describes the observed physical characteristics of the spectral line and considers several possible origins. (auth)

58564 LIMITING MASS OF A NEUTRON STAR. Leung, Y. C. (Southeastern Massachusetts Univ., North Dartmouth); Wang, C. G. Nature (London) Phys. Sci.; 233: No. 40, 99-100 (4 Oct 1971).

In this discussion the interior of a pulsar is divided into three distinct density regions. Region 1 has a density $<5 \times 10^{11}$ g/cm^3, region 2 a density of 5×10^{11} to 10^{15} g/cm^3, and region 3 a density $>10^{15}$ g/cm^3. In region 1 the pressure is generated by an electron gas obeying the laws of atomic physics, and the semi-empirical nuclear mass formula plays an important part in the equation of state. The material in region 2 is compressed to nuclear densities and the pressure is generated by the Fermi energy of the neutron gas. Implications of this treatment are discussed. At higher densities the production of hyperons has a dramatic effect on the equation of state, and it is not clear whether these hyperons can be treated as free nucleons. There is also a limiting pressure for any density beyond which the velocity of sound would be greater than the velocity of light, and a further condition is that the equation of state should merge with the "limit of causality" line. The problem of the limiting mass of a neutron star is therefore a question of how "stiff" the equation of state should be before it is merged with the limit of causality. It is concluded that it seems unlikely that neutron stars can be more massive than, say, 0.5 $M_\odot$. (UK)

58565 COSMIC X-RAY ASTRONOMY. Adams, D. J. (Univ. of Leicester, Eng.). Contemp. Phys.; 12: No. 5, 471-93(Sep 1971).

The results obtained from observations of the celestial x radiation over the past nine years are reviewed. Emphasis is placed on the study of the discrete sources, particularly those that have been identified with astronomical objects known from optical and radio studies. The isotropic background x radiation is dealt with briefly, and the theories that account for x ray production on the atronomical scale are mentioned where applicable. Finally, the observations needed to further advance this subject are discussed. (auth) (UK)

58566 ACCURATE RADIO AND OPTICAL POSITIONS OF 3C 273B. Hazard, C. (Cambridge Univ., Eng.); Sutton, J.; Argue, A. N.; (and others). Nature (London) Phys. Sci.; 233: No. 40, 89-91(4 Oct 1971).

New measurements confirmed that 3C 273B and the associated quasi-stellar object are coincident. (auth) (UK)

58567 POSSIBLE SELECTION EFFECT IN MEASUREMENT OF QUASAR REDSHIFTS. Roeder, R. C. (Univ. of Toronto). Nature (London) Phys. Sci.; 233: No. 39, 74-5(27 Sep 1971).

The distribution of the emission line redshifts of quasars has been the subject of a number of investigations in which the power spectrum of the distribution has been computed, and attention has been drawn to the existence of sharp peaks in the distribution, at redshifts Z = 1.95 and ~0.06, with possibly others at multiples of 0.06. In any studies of the power spectrum, or comparisons of the heights of peaks in different ranges of redshift, any effects of observational selection should first be removed from the distribution, and observational data are presented that indicate that at least one selection effect can be detected in observed distributions; this affects only intervals of redshift >0.1. The implication is that the observed quasar redshift distribution does not represent the true distribution. A more accurate approximation to the true distribution should allow for an "ease of measurement effect", which is a function of redshift. The existence of such an effect also means that the heights of peaks in the redshift distribution separated by intervals greater than ~0.1 in redshift cannot be directly compared for statistical purposes. (UK)

58568 OPTICAL MONITORING OF RADIO SOURCES. III. FURTHER OBSERVATIONS OF QUASARS. Tritton, K. P.; Selmes, Rosemary A. (Royal Greenwich Observatory, Hailsham, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 453-69(1971).

Results for 20 quasars are reported from the Herstmonceux program of optical monitoring of radio sources. New variables are 3C 175 and 3C 232, and variations suspected in earlier work were confirmed for 3C 249.1, 3C 263 and 3C 380. All quasars in the sample have now been found variable. Light curves are shown that demonstrate the difference between the "optically violently variable" sources and the other quasars. A new major outburst was recorded for 3C 454.3. No well-defined periodicities were apparent for any quasar in the sample. (auth) (UK)

58569 MODE CHANGING IN PULSAR RADIATION. Lyne, A. G. (Univ. of Manchester, Jodrell Bank, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 27P-32P(1971).

The integrated profiles of the radio pulses from PSR 1237 + 25 and PSR 0329 + 54 were found to change abruptly at intervals of some thousands of pulses. The changes were observed mainly in the intensity profiles; the polarization characteristics were only slightly affected. (auth) (UK)

Solar Phenomena

Refer also to abstracts 58682, 58886, and 58888.

58570 (N-71-14166) LONGITUDE DISTRIBUTION OF SOLAR FLARES. Fung, P. C. W.; Sturrock, P. A.; Switzer, P.; Van Hoven, G. (Stanford Univ., Calif. Inst. for Plasma Research). Nov 1970. Contract F44620-69-C-0008. 23p. (NASA-CR-111735; SU-IPR-393). NTIS.

Statistical tests, based on the maximum likelihood method, were performed on flare series extending over several years. If all flares in each plage region are taken into account, a rich spectrum is obtained. If one carries out a similar analysis of a reduced flare series, which includes at most one flare from each plage region, the spectrum is almost devoid of structure, and what structure does remain is not statistically significant. The inference is that solar activity does not display genuine rigid rotation modulation, but that repeated events from individual centers of activity yield modulation that may be mistaken for rigid-rotation modulation. A test for correlation between reduced flare series for the northern and southern hemispheres gives no significant correlation. This test therefore yields no support to the hypothesis that solar activity is modulated by planetary effects. (auth) (STAR)

58571 FORMATION OF PROMINENCES. Pikel'ner, S. B. (Shternberg State Astronomical Inst., Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 276-8(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 357-9(Mar-Apr 1971).

The formation of prominences is usually linked to the thermal instability of the radiatively cooled corona. Energy losses through heat conduction to the chromosphere and production of solar wind also play a significant role in the thermal balance of the corona, however. The magnetic field supporting the prominence must be shaped as an arc with a pit at the top, it appears, as required by hydrodynamic stability conditions. Heating would be minor in such a pit, since Alfvén waves and slow waves do not propagate across the lines of force, and fast waves become attenuated through refraction. The temperature difference is responsible for the stream along the lines of force, while the gas flows into the pit to condense there. Calculations yield the change in parameters along the tube of force, and the magnitude of the gas stream. It takes one to two days for the prominence to form, with the excess of gas trickling down into the chromosphere. (auth)

58572 PROFILES OF THE CORONAL LINES $\lambda\lambda$ 5303 Å, 6374 Å BASED ON LARGE (53 CM) CORONOGRAPH OBSERVATIONS. Makarova, V. V.; Makarov, V. I.; Nilol'skii, G. M. (State Astronomical Observatory, Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 279-83(Sep-Oct 1971).
Translated from Astron. Zh.; 48: No. 2, 360-4(Mar-Apr 1971).

XUM

Profiles of lines were constructed for different distances from the solar limb from out-of-eclipse plates taken of the coronal lines λλ 5303 and 6374 Å on the 53-cm coronograph in 1967–1969. The profiles exhibited a Doppler shape, within the limits of error of the observations. Nonthermal velocities are ≈20 km/sec. (auth)

58573 DYNAMICAL PROCESSES RESPONSIBLE FOR ORIGIN OF CORONAL FORMATIONS. Guseinov, R. E. (Shemakha Astrophysical Observatory, Baku). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 284-9(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 365-72(Mar-Apr 1971).

Arguments are adduced in support of the view that a coronal flare—an active or quiescent prominence—can originate as a result of compression of the coronal plasma with a longitudinal magnetic field in response to pressure exerted by the "magnetic wall," depending on the initial physical conditions (temperature, density, magnetic-field strength) in the medium undergoing compression and the compression rate. The differential equation for the energy balance is derived (without assuming adiabatic compression). The final density in the tube of force, the initial internal longitudinal field, the maximum internal longitudinal field, and time variations of the field are estimated. These estimates are found to be in excellent agreement with data on coronal flares, and active and quiescent prominences. Arguments on some aspects of emission connected with coronal flares are also advanced. (auth)

58574 E-22 FRENCH EXPERIMENT ABOARD THE OGO-5 AMERICAN SATELLITE. Bertaud, J. L. (Centre National de la Recherche Scientifique, Verrieres-le-Buisson, France). Rech. Spatial.; 10: No. 3, 5-8(May 1971). (In French).

Results obtained from geocoronal observations made during the E-22 French experiment on extraterrestrial Lyman–alpha emission and investigations of the hydrogen envelope surrounding comets are presented. (France)

58575 ORIGIN OF ORGANIC MATTER IN EARLY SOLAR SYSTEM. III. AMINO ACIDS: CATALYTIC SYNTHESIS. Yoshino, Daisuke; Hayatsu, Ryoichi; Anders, Edward (Univ. of Chicago). Geochim. Cosmochim. Acta; 35: No. 9, 927-38(Sep 1971).

When OC, H_2 and NH_3 are allowed to react at 200 to 700°C in the presence of nickel, alumina, or clay catalysts, amino acids are found among the products in yields of 0.01 to 0.1%. Purines, pyrimidines, and hydrocarbons are also formed. Identifications were made by use of an amino-acid analyzer. Although some contamination had occurred, the following amino acids appear to have been definitely synthesized: glycine, α-alanine, β-alanine, sarcosine, aspartic acid, glutamic acid, arginine, histidine, lysine, and ornithine. Evidence is less conclusive for leucine, isoleucine, valine and proline. (auth)

58576 ORIGIN OF ORGANIC MATTER IN EARLY SOLAR SYSTEM. IV. AMINO ACIDS: CONFIRMATION OF CATALYTIC SYNTHESIS BY MASS SPECTROMETRY. Hayatsu, Ryoichi (Univ. of Chicago); Studier, Martin H.; Anders, Edward. Geochim. Cosmochim. Acta; 35: No. 9, 939-51(Sep 1971).

Catalytic synthesis of the following amino acids from CO, ND_3, and D_2 was confirmed mass spectrometrically: glycine, alanine, aspartic and glutamic acids, histidine, lysine, ornithine, and tyrosine. Contamination was ruled out by use of deuterated reactants. It appears that this reaction (a variant of the Fischer–Tropsch synthesis) can produce most of the amino acids seen in meteorites, along with hydrocarbons, purines and pyrimidines. It may have been an important process for the production of prebiotic organic matter in meteorites and planets. (auth)

58577 MOLECULAR SPECTRUM OF SUNSPOT UMBRAE. Sotirovskii, P. (Meudon Observatory, France). Astron. Astrophys.; 14: No. 2, 319-36(Sep 1971).

By means of spectrographic analysis the molecular spectra in three sunspot umbrae were studied. The first step was to try to identify all the molecular lines in the spectral range 4900 to 6450 Å using the method of coincidences. Because of the very high number of spectral lines per Ångström, this method may lead to spurious results; thus it was necessary to make various checks based on line or band intensities. Fourteen molecules were studied; three of them (CN, MgH, and TiO) were extensively analyzed and provided reliable information about the rotational temperatures (3000°K in the largest umbra). In the same way an empirical curve of growth was obtained from the MgH lines that allowed the Mg isotopic ratios to be estimated. The last step was to compute the equivalent widths of molecular lines using Hénoux's sunspot model and to compare the calculations with the observations; thus it was possible to confirm the model and also to evaluate several molecular parameters which were previously unknown (TiO oscillator strengths in the α system) or doubtful (MgH $^2\Pi - {}^2\Sigma$ system oscillator strengths). It is pointed out that all the results are consistent with a microturbulence velocity ξ = 1 km/s in the largest sunspot. (auth)

58578 INTERPLANETARY HYDROGEN CONE AND ITS SOLAR-CYCLE VARIATIONS. Fahr, H. J. (Institut fuer Astrophysik und Extraterrestrische Forschung, Bonn). Astron. Astrophys.; 14: No. 2, 263-74(Sep 1971).

The motion of interstellar hydrogen particles within the solar system was investigated taking into account the thermal motions of the particles. It is shown that the particle density generally decreases with decreasing distances from the Sun due to particle losses by euv ionizations and charge-transfer reactions. Solely in the direction opposite to the approach of interstellar matter a cone of enhanced hydrogen densities is produced. Within this cone the focusing effect of the solar gravitational field gives rise to a density increase of interstellar hydrogen by up to a factor of 6 with respect to the density n_0 outside of the solar system. The densities resulting within the cone and the angular profile width of the cone strongly depend on the temperature of the interstellar gas. Measurements of the intensities of the Lyman-alpha backscatter radiation from the region of this hydrogen cone should not only reveal the actual geometry of the cone, but should directly permit a deduction of this temperature which is unknown so far. Furthermore, it is shown that the geometry of the hydrogen cone is influenced by the radiation pressure of the solar Lyman-alpha radiation which varies within the solar cycle. Consequently, it is to be expected that the cone changes its profile during the 11-year solar activity cycle. The hydrogen cone leads to a density-dependent and temperature-dependent embayment of the magnetic shockfront in a direct which coincides with the location of the sidereal intensity maximum of galactic cosmic rays. (auth)

58579 PROPAGATION OF A SPECTRUM OF ACOUSTIC WAVES IN THE SOLAR ATMOSPHERE. Ulmschneider, Peter (Univ., Wuerzburg, Ger.). Astron. Astrophys.; 14: No. 2, 275-82(Sep 1971).

The propagation of acoustic waves, their transformation into shock waves and their dissipation was computed on basis of the Harvard Smithsonian Reference Atmosphere (HRA) for the Sun. Acoustic frequency spectra of Stein (1968) were used and the effect of radiative damping included. Good agreement was found between the heating produced by these waves and the computed radiative losses in the chromosphere. Coronal heating proved more difficult to explain. (auth)

58580 SOLAR TRANSITION LAYER AND SOLAR ACTIVE REGIONS. Reimers, D. (Univ., Kiel). Astron. Astrophys.; 14: No. 2, 198-202(Sep 1971).

An empirical minimum equator model of the solar transition layer and inner corona was constructed using observations of the solar radio and ultraviolet spectra and of the white and the monochromatic corona. The sudden temperature rise in the transition layer determined from ultraviolet spectra e.g., by Dupree and Goldberg (1967) was confirmed by observations of the solar radio spectrum. A coronal temperature of $(1.4 \pm 0.1) \times 10^6$°K, an electron density in agreement with the absolute scale of v. d. Hulst (1950), and a coronal abundance log N_{Si} = 7.56 ± 0.1 were derived for transforming Pottasch's (1967) relative scale of abundances into an absolute one. The one-parameter model of solar-active regions (Reimers, 1971), which establishes relations between the temperature and density of the corona and the temperature gradient in the solar-transition layer, was confirmed by the extreme-ultraviolet spectroheliograms from OSO IV and by radio spectra of active regions as well as by observations of coronal rays and condensations. Thus, a very simple empirical method is obtained for determining the transport of mechanical energy into the corona. In very strong active regions the mechanical energy flux is enhanced by factors up to ≈20, which corresponds to $\approx 10^7$ erg/cm^2 s. (auth)

58581 ANGULAR MOMENTUM AND SHORT-TERM DIRECTIONAL FLUCTUATIONS OF THE SOLAR WIND FROM VELA 3 DATA. Hardorp, Johannes (State Univ. of New York, Stony Brook). Astron. Astrophys.; 14: No. 2, 210-14(Sep 1971).

From recently published lists of detailed solar-wind observations by the Vela 3 satellites, it is shown that the Sun's loss of angular momentum can be derived from time averages of solar-wind density, velocity, and direction without danger of statistical bias. Brandt's result of an e-folding time for solar spin-down of the order of the age of the Sun is therefore confirmed. Directional fluctuations of the solar wind on a time scale of 3 hours or shorter show a dispersion of 1° only, in contrast to the 3° dispersion of slow variations. Since tail rays of comet Morehouse 1908 III display wiggles with a directional dispersion of 0.7°, it is concluded that the solar wind acts on the inner parts of ionic comet tails in a direct way. (auth)

58582 LARGE-SCALE PROPERTIES OF THE INTERPLANETARY MAGNETIC FIELD. **Schatten, Kenneth H. (Goddard Space Flight Center, Greenbelt, Md.). Rev. Geophys. Space Phys.; 9: No. 3, 773-812(Aug 1971).**

Knowledge of the large-scale properties of the interplanetary magnetic field is reviewed. The early theoretical work of Parker is presented, along with the observational evidence supporting his Archimedes spiral model. The variations present in the interplanetary magnetic field from the spiral angle are related to structures in the solar wind. The causes of these structures are found to be either nonuniform radial solar-wind flow or the time evolution of the photospheric field. The coronal magnetic models are related to the connection between the solar magnetic field and the interplanetary magnetic field. The direct extension of solar field–magnetic nozzle controversy is discussed, along with the coronal magnetic models. The effect of active regions on the interplanetary magnetic field is discussed with particular reference to the evolution of interplanetary sectors. The variation of the interplanetary magnetic-field magnitude is shown throughout the solar cycle. The percentage of time the field magnitude is greater than 10 γ is shown to closely parallel sunspot number. The suggested influence of the Sun's polar field on the interplanetary field and alternative views of the magnetic-field structure out of the ecliptic plane are presented. In addition, a variety of significantly different interplanetary-field structures is discussed. 44 references. (auth)

58583 NEW OBSERVATIONS OF SATELLITE LINES IN THE SOLAR X-RAY SPECTRUM. **Parkinson, J. H. (Univ. of Leicester, Eng.). Nature (London) Phys. Sci.; 233: No. 38, 44-5(20 Sep 1971).**

Several weak satellite lines were observed for the first time in solar x-ray spectra obtained from four Bragg crystal spectrometers launched on a Skylark rocket on Dec. 6, 1970 from Sardinia. The proximity of these lines to the H3-like $1S^2-1S\ 2p$ lines indicated that they were all transitions of type $1S^2\ nl-1S\ 2p\ nl$. The He-like line systems of 0 VII, Ne IX, Mg XI, and Si XIII were observed, and the Ne and Mg spectra are reproduced, indicating the resonance, intercombination, and forbidden lines. The intensities of the respective resonance lines are discussed; the results strongly support the assumption of dielectronic recombination as the principal mechanism for the formation of the n = 2 satellite lines. (UK)

58584 PHYSICS OF SUNSPOTS. PART IV. **Jakimiec, Jerzy (Astronomical Observatory, Wroclaw). Postepy Astron.; 19: No. 3, 199-213(1971). (In Polish).**

The problem of constructing complete, hydromagnetic models of the photospheric layers of a spot is considered, taking all relevant observational data into account. Much attention is devoted to the question of determining the distribution of the magnetic forces in the spot. (auth)

58585 OBSERVATIONAL DATA ON THE SOLAR WIND. **Sroczynska, Magdalena (Astronomical Observatory, Warsaw). Postepy Astron.; 19: No. 3, 215-23(1971). (In Polish).**

A short review of the observational data on solar wind (near the orbit of the Earth) is given. (auth)

58586 FLOCCULE THEORY AND PLANETARY FORMATION. **Aust, C.; Woolfson, M. M. (Univ. of York, Eng.). Mon Notic. Roy. Astron. Soc.; 153: No. 3, 21P-25P(1971).**

A three-dimensional model of the formation of planets by the floccule theory was examined with the aid of a computer. It was found to lead to a nonplanar system with many proto-planets in retrograde orbits. (auth) (UK)

58587 EFFECT OF SCATTERED LIGHT ON THE FACULA-TO-PHOTOSPHERE CONTRAST. **Pande, M. C.; Tripathi, B. M.; Guar, V. P. (Uttar Pradesh State Observatory, Naini Tal, India). Bull. Astron. Inst. Czech.; 22: No. 4, 161-2(1971).**

The measured facula-to-photosphere contrast in the continuum radiation corrected for the scattered light should yield a hotter average facula model than the models derived without such a correction. (auth)

58588 RELATION BETWEEN ELECTRIC CONDUCTIVITY IN FACULAE AND IN THE BILDERBERG MODEL OF THE PHOTOSPHERE. **Kopecky, M.; Soyturk, E. (Astronomical Inst., Ondrejov, Czech.). Bull. Astron. Inst. Czech.; 22: No. 4, 154-6(1971).**

The value of the electric conductivity at different optical and geometrical depths in the Bilderberg model of the photosphere and low chromosphere and in the model of faculae is given. In the case of inhomogeneous electric conductivity in the active regions of the Sun, relatively complicated systems of electric currents must exist in the active regions. (auth)

58589 DEPENDENCE OF MOLECULAR DISSOCIATION EQUILIBRIUM ON MAGNETIC FIELD STRENGTH IN SUNSPOTS. **Gaur, V. P.; Pande, M. C.; Tripathi, B. M.; Joshi, G. C. (Uttar Pradesh State Observatory, Naini Tal, India). Bull. Astron. Inst. Czech.; 22: No. 4, 157-60(1971).**

It is shown that the total number of CO, CN, C_2, OH, NH, and CH molecules varies significantly with magnetic field strength in sunspots. The equivalent widths of first two overtone lines of CO belonging to the 0–2 vibration–rotation band as a function of magnetic field strength are also given. It appears that up to 2500 gauss the equivalent widths change linearly with magnetic field strength. (auth)

58590 DIRECT OBSERVATION OF COSMIC-RAY ENERGY LOSSES. **Gleeson, L. J. (Monash Univ., Clayton, Australia); Palmer, I. D. Astrophys. Space Sci.; 12: No. 1, 137-46(Jul 1971).**

During the decay of solar cosmic-ray events, cosmic rays with kinetic energies of about 1 MeV are convected outward with the solar wind. It is shown that, with currently available observations, it should be possible to demonstrate directly the energy losses that are occurring. Observations from two spacecraft on the same heliocentric radial line are required. Observations from Venera-4 and Imp-F were used. A simple and direct demonstration would be provided by the observation of nearly mono-energetic pulses convected between the two spacecraft, but no such pulses were found to be present. A second method depends upon observing the ratio of the integral fluxes at the two spacecraft and comparing this with the value predicted by theory. The relevant theoretical analysis is given. It is shown that, in order to discriminate between energy-loss processes, the spacecraft must be well separated. For spacecraft at Earth's orbit and the orbit of Venus the integral-flux ratio predicted with energy loss due to adiabatic deceleration is a factor of three higher than that predicted with no energy loss. Comparisons of integral-flux ratios for two events observed on spacecraft separated by approximately 0.1 AU gave inconclusive results. In view of the importance of energy-loss processes in the propagation of cosmic rays it is suggested that others with access to relevant data might continue this investigation. (auth)

58591 PLANETARY FORMATION FROM CHARGED BODIES. **Williams, I. P. (Queen Mary Coll., London). Astro phys. Space Sci.; 12: No. 1, 165-71(Jul 1971).**

The suggestion of Sarvajna that a charged body that has been ejected from the Sun can be captured in orbit because of electromagnetic effects was reinvestigated. It was concluded that the charge assumed by Sarvajna is too high by many orders of magnitude. An alternative scheme is proposed in which the charge requirement is much more realistic, and it is shown that this scheme is feasible. (auth)

58592 SOLAR FLARE PREDICTION. **Brailovskii, V. L.; Brailovskaya, I. Yu. (Moscow State Univ. Inst. of Electrically Controlled Machines, Moscow). Dokl. Akad. Nauk SSSR; 198: No. 2, 319-22(11 May 1971). (In Russian).**

A number of compilations of data on solar activity in 1966 were used in a study of solar-flare prediction by statistical methods on a computer. The data included total sunspot area of a given group, the area of the maximum spot within it, and the number of spots in a group. For each flare, the moment of its beginning and ending, heliographic coordinates, area, and brightness were entered. Various functions were designed from these data for handling by computer: previous history of flare activity, spot groups as characterized by the logarithm of the number of spots, breaking-up of groups, inequality of area distribution, and the effect of neighboring groups of spots. The authors evaluate this work as the first step of their development of solar-flare prediction. (K.S.W.)

58593 ABUNDANCE OF CHLORINE IN THE SUN. **Lambert, D. L. (Univ. of Texas, Austin); Mallia, E. A.; Brault, J. Solar Phys.; 19: No. 2, 289-96(Sep 1971).**

A low-noise photoelectric scan which includes the predicted position of the Cl I transition $4s\ ^4P_{5/2}2-4p\ ^4D^0_{5/2}$ provides inconclusive evidence for the presence of the line in the solar photospheric spectrum. An upper limit log N(Cl) $\leq$ 5.5 is derived. It is pointed out that the fundamental vibration rotation band of HCl at 3.3 μ should be detectable in the sunspot spectrum unless log N(Cl) < 4.6. Sunspot spectra may also provide the isotopic abundance ratio $N(^{35}Cl)/N(^{37}Cl)$. A new derivation of the chlorine abundance for the Orion nebula is presented: log N(Cl) $\approx$ 5.8. It is suggested that a cosmic abundance log N(Cl) = 5.5 to 5.8 be adopted. (auth)

58594 POWER SPECTRUM ANALYSIS OF GRANULAR INTENSITY FLUCTUATIONS AND VELOCITIES. Reiling, H. (Univ., Goettingen, Ger.). Solar Phys.; 19: No. 2, 297-313 (Sep 1971).

An exceptionally highly resolved spectrogram (obtained by Livingston at Kitt Peak) was used to derive rms values for both the intensity fluctuations in the continuum and the granular velocities in the Ba II line λ5853.69 by means of the power spectrum analysis. The main results were: (1) a corrected rms value for the intensity fluctuations of 3.8%; (2) a nearly constant power level in the one-dimensional power spectrum per unit wave number within the range 0.00018 to 0.01 km^{-1} ($\triangleq$34000 to 600 km); (3) a corrected rms value for the granular velocities of ~1 km/s. The behavior of the asymmetry of the Ba II line in individual "bright" and "dark" continuous streaks can be explained by a superposition of two shifted symmetric line profiles originating from pure granular and intergranular regions, respectively. The impurity of "dark" and "bright" streaks amounted to less than ~10%, the mean relative velocity of granular and intergranular regions being again ~1 km/s. The microturbulence in the intergranular regions is indicated to be larger than in the granular ones. (auth)

58595 INTERFEROMETRIC MEASUREMENTS OF 142 SOLAR WAVELENGTHS. O'Brien, James E. (Georgetown Coll. Observatory, Washington, D. C.). Solar Phys.; 19: No. 2, 314-22(Sep 1971).

The wavelengths of 142 solar absorption lines, in light taken from the center of the solar disk, and in the wavelength region 4675 to 6275 Å, were determined by interferometric comparison with the standard wavelengths of ^{198}Hg. A Fabry–Pérot interferometer was crossed with a high-dispersion, Wadsworth-type spectrograph by a method similar to that used at Allegheny and Mount Wilson Observatories in the original determinations of the IAU solar wavelength standards of 1928. The wavelengths of 68 solar iron lines were compared with hollow-cathode wavelengths, and differences between the resulting wavelength shift and that predicted by relativity theory calculated. (auth)

58596 ABSOLUTE INTENSITY CALIBRATIONS OF SOLAR K-LINE PROFILES. Pasachoff, Jay M. (California Inst. of Tech., Pasadena). Solar Phys.; 19: No. 2, 323-9(Sep 1971).

Individual K-line profiles from elements of fine structure on the surface of the Sun were calibrated absolutely. The continuum calibrations of Labs and Neckel and of Houtgast and Namba were considered, and the average K-profile was scaled to that of White and Suemoto. The ranges of intensities across a high-resolution spectrogram were tabulated for various parts of the line profile. Although the spatially-averaged value for K_3 of 4.2% of the continuum corresponded to a brightness temperature of 4155 K, minimum and maximum values were 3980 and 4360 K, respectively. Similarly, K_{2v} ranged from 4200 to 4560 K, and K_{2r} from 4180 to 4460 K in small elements about 1 arc sec across. (auth)

58597 ISOTOPES OF MAGNESIUM IN THE SOLAR ATMOSPHERE. Boyer, R.; Henoux, J. C.; Sotirovski, P. (Observatoire de Paris, Meudon, France). Solar Phys.; 19: No. 2, 330-7(Sep 1971).

MgH $A^2\Pi - X^2\Sigma$(0.0), (1.1), (2.2), (0.1), and (1.2) absorption bands in a sunspot spectrum were analyzed. By two different methods, which are almost independent of the estimated value of the correction for stray light, the solar isotopic ratios of magnesium were determined. These ratios were equal to the terrestrial ones — ^{24}Mg : ^{25}Mg : ^{26}Mg = 80 : 10 : 10. (auth)

58598 TWO-DIMENSIONAL OBSERVATIONS OF THE VELOCITY FIELD IN AND AROUND SUNSPOTS. Sheeley, N. R. Jr. (Kitt Peak National Observatory, Tucson, Ariz.); Bhatnagar, A. Solar Phys.; 19: No. 2, 338-46(Sep 1971).

Doppler spectroheliograms of sunspots and their surroundings were obtained with a spatial resolution approaching one second of arc and a time resolution of 20 s per frame. Observations of 5 sunspots, located 18°, 45°, 56°, 60°, and 72° from the disk center, respectively, showed considerable long-lived fine structure and, in particular, indicated the following: (1) The Evershed outflow terminated in spoke-like structures that constitute the ragged outer boundary of the penumbra. Some of these spokes extended more than 8000 km beyond the average outer boundary. (2) Although there was considerable long-lived fine structure of both Doppler polarities in the extra-penumbral photosphere, the spatially-averaged horizontal flow was outward for roughly 10,000 km beyond the outer boundary of the penumbra. This extra-penumbral velocity field was distinct from the Evershed flow, and, in particular, did not represent its extension beyond the end of the penumbral spokes. Although these results are based on observations of relatively few sunspots, they do suggest that if magnetic fields are carried outward from sunspots by material motions, then these motions are more like the supergranulation than an extension of the Evershed velocity. (auth)

58599 ELECTRON DENSITIES DERIVED FROM LINE INTENSITY RATIOS: BERYLLIUM ISOELECTRONIC SEQUENCE. Munro, Richard H.; Dupree, A. K.; Withbroe, George L. (Harvard Coll. Observatory, Cambridge, Mass.). Solar Phys.; 19: No. 2, 347-55(Sep 1971).

A direct method for determining electron densities from emission-line intensities of ions in the beryllium isoelectronic sequence is described and then applied to the analysis of extreme ultraviolet C III and O V spectra from both quiet and active areas in the solar transition region. The results are consistent with a value of $N_eT_e = 6 \times 10^{14}$ cm^{-3} K for the quiet Sun at temperatures of 5×10^4 to 3×10^5 K. Electron densities are approximately five times greater in active regions than in the quiet Sun. (auth)

58600 SOFT SOLAR X RAYS AND SOLAR ACTIVITY. V. RELATION OF THE COURSE OF SOFT X-RAY FLUCTUATIONS TO THE COURSE OF SOLAR ACTIVITY, 9 MARCH, 1967–18 MAY, 1968. Teske, Richard G. (Univ. of Michigan, Ann Arbor). Solar Phys.; 19: No. 2, 356-78(Sep 1971).

Soft solar x rays in the wavelength interval 8 to 12 Å were observed from OSO III. The totality of the observations that were made between March 9, 1967 and May 18, 1968 is summarized graphically and compared to the course of solar activity as observed at other wavelengths, with particular emphasis upon visible activity. (auth)

58601 SOLAR ROTATION: DIRECT EVIDENCE FROM PROMINENCES FOR A WESTWARD WIND. Livingston, W. (Kitt Peak National Observatory, Tucson, Ariz.). Solar Phys.; 19: No. 2, 379-83(Sep 1971).

Hα and K-line spectra of quiescent prominences, taken with the slit placed normal to the limb, commonly reveal a gas streaming (5 to 50 km/s) that is peculiar to the upper edge of these objects. On the average this streaming is unidirectional and consistent with a hypothetical east–west wind. (auth)

58602 ABUNDANCE OF HELIUM IN PROMINENCES AND IN THE CHROMOSPHERE. Hirayama, Tadashi (Tokyo Astronomical Observatory). Solar Phys.; 19: No. 2, 384-400(Sep 1971).

The abundance of helium relative to hydrogen was spectroscopically determined in prominences and in the chromosphere by using 1952, 1958, 1962, and 1966 eclipse data. Care was taken in the intensity calibration of emission lines, the self-absorption, and the departure from local thermodynamic equilibrium. It was found from the line profiles and intensities of prominences and the chromosphere that the neutral helium lines were emitted in the metal–hydrogen emitting region where the kinetic temperature is low enough, 6000 ~ 8000 K, so that only the ionization due to uv radiation from the corona can explain the intensity of neutral helium emission. It was also found that the intensity ratio of He I 3888.65 to Hα 3889.05 increased towards the upper boundaries of prominences and of the chromosphere and that it approached a universal limiting value, both in various prominences or in the chromosphere, where it was considered that the ionization of neutral helium and hydrogen is nearly complete. From these facts the helium to hydrogen number ratio was found to be 6.5 ± 1.5%. A new schematic model of the chromosphere is presented where spicules have no hot region of emitting neutral helium lines. Here it is suggested that the kinetic temperature of spicules, 6000 ~ 8000 K, would be primarily determined by the radiation temperature of the corona and the transition region beyond the Lyman continuum of hydrogen which happens to be around those temperatures. (auth)

58603 ENERGY BALANCE IN COOL QUIESCENT PROMINENCES. Poland, A.; Anzer, U. (National Center for Atmospheric Research, Boulder, Colo.). Solar Phys.; 19: No. 2, 401-13(Sep 1971).

The energy balance for cool quiescent prominences was examined using a 6000-km, 6000 K isothermal slab model prominence with a density gradient dictated by a modified Kippenhahn–Schlüter model. The model was irradiated from both sides by the coronal, chromospheric, and photospheric radiation fields. The radiative transfer problem was solved in detail for the Lyman continuum and Hα to determine the net radiative energy loss for hydrogen. An estimate of the energy loss for Ca II H and K indicated that this source of energy loss is unimportant when compared with the hydrogen radiation. The radiative energy loss is easily balanced by the conductive energy gain from the corona. The only difficulty with the model was that the total hydrogen density must be of the order of $3 \times 10^{12}/cm^3$ to match the $n = 2$ population density of $5 \times 10^4/cm^3$ obtained from observation. To support a prominence of this density and a thickness of 6000 km against gravity requires magnetic fields of the order of 20 G which is much higher than the average magnetic field in quiescent prominences deduced from limb observations. Two possible explanations for this discrepancy are given. (auth)

58604 HELIUM RADIATION IN PROMINENCES. Yakovkin, N. A.; Zeldina, M. Yu. (University Observatory, Kiev). Solar Phys.; 19: No. 2, 414-30(Sep 1971).

It is shown that the emission of quiescent and loop prominences in the helium D_3 line and in the 4686 Å line of He^+, respectively, occurs at low temperatures —of the order of 7000 K. The ionization of neutral helium is produced by short-wave solar radiation, which is absorbed in the outer layers of filaments composing a prominence. The population of helium triplet levels in prominences is determined by recombinations and subsequent resonance scattering of photospheric radiation. Transitions from triplet to singlet levels caused by electron collisions considerably reduce the line brightness. Emission of ionized helium in the 4686 Å line arises in prominence surface layers as well. In quiescent prominences the emission is very faint and is due to recombination; the second ionization is caused by the far ultraviolet radiation. In flare-like events ionized helium emits due to charge-exchange collisions. The symmetrical resonance charge-exchange of α particles is caused by helium ions in corpuscular streams probably generated in photospheric layers. Due to increased radiation losses the temperature of the prominence under the action of the stream is negligibly increased. With a stream density equal to 5×10^8 cm^{-3} and velocity 300 km/s the theoretical intensity of the 4686 He^+ line is some hundreds of microångströms and agrees with observations of Goldberg–Rogozinskaya (1962, 1965) and others. (auth)

58605 ABUNDANCE OF CALCIUM IN THE SOLAR CORONA. Fisher, Richard R. (Univ. of Hawaii, Honolulu). Solar Phys.; 19: No. 2, 431-5(Sep 1971).

Measured values for the total intensity of the continuum and the ratio of integrated intensities $I(\lambda 5694)/I(\lambda 5446)$ were used to estimate the fraction of electrons along the line of sight contributing to the excitation of Ca XV. This estimate of electron density along with an estimate of the dimension of the emitting region was used to find a value of the abundance of Ca in the solar corona. The estimated abundance was $\log N_{Ca}/N_H = -4.35$. (auth)

58606 MONOCHROMATIC OBSERVATIONS OF A CORONAL LOOP. Fisher, Richard R. (Univ. of Hawaii, Honolulu). Solar Phys.; 19: No. 2, 436-9(Sep 1971).

An isophotal map of a small coronal loop, obtained from a coronagraph observation through a solid Fabry–Perot interferometer, was used to estimate the variation of emission per unit volume and the pressure gradient at the top and sides of the loop. The magnitude of the magnetic field necessary to maintain the estimated pressure gradients was found to be $|\bar{H}^2| = 30$ G^2. (auth)

58607 DISTRIBUTION OF MATERIAL AS A FUNCTION OF TEMPERATURE IN THE POST-FLARE LOOP SYSTEM OF AUGUST 12, 1970. Fisher, Richard R. (Univ. of Hawaii, Honolulu). Solar Phys.; 19: No. 2, 440-50(Sep 1971).

Observations of the post-flare loop system formed after the east limb proton flare of August 12, 1970 include (a) sets of filtergrams from which photographic subtractions were constructed and (b) spectra from which a distribution of electron density as a function of temperature for three coronal regions is derived. The filtergrams show no indications of radial velocities in excess of 80 km/s. The spectra indicate an increase in density at the tops of the loops with most of the material at a relatively cool temperature: $N_e \simeq 6.0 \times 10^{10}$, $N = 3 \times 10^5$ K. The distribution functions obtained for areas just above and just below loops indicate a lower electron density and the presence of material at high temperatures, $N_e \simeq 2.0 \times 10^{10}$ and $T \simeq 2.6 \times 10^6$ K (above the loops) and $T_e > 4.4 \times 10^6$ K for material below the loops. (auth)

58608 MASS MOTIONS IN A FLARE SPRAY. McCabe, Marie K. (Univ. of Hawaii, Honolulu). Solar Phys.; 19: No. 2, 451-62(Sep 1971).

High-velocity Hα ejections were observed in association with an important solar flare on March 12, 1969, and simultaneously with Type II followed by Type IV radio emission detectable to 3 to 4° solar radii ($R_\odot$) from the center of the Sun. From a sequence of Hα coronagraph photographs, trajectories and velocity determinations were made for fragments of the flare spray which was visible to a distance of 2 $R_\odot$. The temporal and spatial relationship between the optical and radio events is discussed. The mass motions appear to be controlled by the gravitational field while the fragments move in the direction of the open magnetic field lines. (auth)

58609 MAGNETIC FIELDS, BREMSSTRAHLUNG, AND SYNCHROTRON EMISSION IN THE FLARE OF OCTOBER 24, 1969. Zirin, H. (California Inst. of Tech., Pasadena. Carnegie Institution of Washington, D. C.); Pruss, Gail; Vorpahl, Joan. Solar Phys.; 19: No. 2, 463-71(Sep 1971).

An impulsive flare October 24, 1969 produced two bursts with virtually identical time profiles of 8800-MHz emission and x rays above 48 keV. The two spikes of hard x rays corresponded in time to the times of sharp brightening and expansion in the Hα flare. The first burst was not observed at frequencies below 3000 MHz. This cutoff was ascribed to plasma cutoff above the low-lying flare. A model of the flare based on Hα observations at Big Bear showed that the density of electrons with energy above 10 keV was 5×10^7 if the field density was 10^{11}. The observed radio flux would be produced by this electron distribution with the observed field of 200 G. The Hα emission accompanying the hard electron acceleration was presumed due to excitation of the field atoms by the hard electrons. (auth)

58610 FARADAY ROTATION DISPERSION AND THE DISTRIBUTION OF POLARIZATION CHARACTERISTICS OF TYPE III BURSTS. Fokker, A. D. (Univ., Utrecht). Solar Phys.; 19: No. 2, 472-9(Sep 1971).

Some results on the distribution of polarization characteristics of Type III bursts obtained by Chin, Lusignan, and Fung (1971) are analyzed in terms of the effects of Faraday-rotation dispersion on fully polarized signals with small axial ratios of the polarization ellipse. (auth)

58611 PLANETARY INFLUENCES ON THE LARGE-SCALE DISTRIBUTION OF SOLAR ACTIVITY. Ambroz, P. (Observatory, Ondrejov, Czech.). Solar Phys.; 19: No. 2, 480-2(Sep 1971).

Recently a conspicuous correlation between the degree of solar activity and the value of tidal force due to planets was published by Bigg and Mulhall (1967). These results may be accepted as a good reason for a working hypothesis about the possible contribution of extrasolar influence on the solar activity formation. The aim of the present short note was to check the reality of existence of a spatial relationship between the solar surface area being influenced by the planetary tidal force and the distribution of calcium flocculi. (auth)

58612 SOLAR LONGITUDE DEPENDENCE OF PROTON-EVENT DELAY TIME. Barouch, E.; Gros, M.; Masse, P. (CEN de Saclay, Gif-sur-Yvette, France). Solar Phys.; 19: No. 2, 483-93(Sep 1971).

The relationship between heliographic longitude and the delay between flare occurrence and solar proton observation was studied using results obtained aboard HEOS A1 during 1969. The result obtained differed from previous findings. This was ascribed to the formation of a long-lived magnetic field configuration close to the Sun associated with a particular group of active regions. (auth)

58613 VELOCITY AND TEMPERATURE OF THE SOLAR WIND FROM DATA OBTAINED USING THE MODULATION TRAP ON INTERPLANETARY STATION VENERA-3. Gringauz, K. I.; Zastenker, G. N.; Khokhlov, M. Z. Cosmic Res. (USSR) (Engl. Transl.); 8: No. 6, 868-71(Nov-Dec 1970).

Translated from Kosm. Issled.; 8: No. 6, 948-51(Nov-Dec 1970).

The modulation charged-particle trap carried by Venera-3 was used to carry out numerous measurements of the energy spectra of the ionic component of the solar wind in the period from Nov. 1965 through Jan. 1966. These energy spectra were used to determine the temperature of the ions and the velocity of the solar wind by comparing them with trap readings calculated in advance on the basis of a stipulated model of the wind. (W.D.M.)

XUM

58614 SPECTRAL STUDY OF SUNSPOT NUMBER AND SOLAR RADIO FLUX BETWEEN 600 AND 9400 MHz. Rao, D. R. K. (Colaba and Alibag Observatories, Bombay). Proc. Indian Acad. Sci., Sect. A; 73: No. 5, 223-31(May 1971).

The relationship between the solar activity, as represented by sunspot number and the slowly varying component of solar radio emission at frequencies from 600 to 9400 MHz, was studied for high solar activity (1857–58), declining phase of moderate solar activity (1961–62), and ascending phase of moderate solar activity (1965–66). Regression and auto-spectrum analyses show that the association of the slowly varying radio emissions with sunspot activity is best around 3750 MHz for the high-solar-activity period, around 2800 MHz for moderate activity during the declining phase, and in between 2800 and 3750 MHz for the ascending phase of activity. The coherence between radio flux at frequencies from 600 to 9400 MHz was high and free from large fluctuations up to wavelengths as short as 7 days in the years 1961–62. At 9400 MHz, however, it was high and steady for wavelengths in excess of about 15 days. At the solar synodic rotation period, the phase difference between the sunspot number and the slowly varying component shows little change with the wavelength of the radio emission. (auth)

58615 SHOCK-FREE DECELERATION OF THE SOLAR WIND? Wallis, Max (Royal Inst. of Tech., Stockholm). Nature (London); Phys. Sci.; 233: No. 37, 23-5(3 Sep 1971).

It is stated that ionizing interactions can cause shock-free transonic deceleration both according to the hydrodynamic description of the solar-wind interaction with interstellar hydrogen and because of the presence of suprathermal ions ahead of comets and nonmagnetic planets. (auth) (UK)

58616 CURRENT SHEET MAGNETIC MODEL FOR THE SOLAR CORONA. Schatten, Kenneth H. (Goddard Space Flight Center, Greenbelt, Md.). Cosmic Electrodyn.; 2: No. 2, 232-45(Jul 1971).

A new magnetic model is developed and compared with previous models and the observed solar corona. An attempt is made to more accurately compute the three-dimensional currents flowing in the solar corona. Physical reasons are given that require most of the large-scale currents flowing in the solar corona to lie near thin sheets. The current sheets are not constrained into any particular geometry or symmetry as in the previous models of Altschuler and Newkirk (1969) and Schatten et al. (1969). A comparison with the axisymmetric, isothermal MHD solution of Pneuman and Kopp (1970) suggests that the model is able to simulate to high accuracy an isothermal corona. A comparison of the model with the May 30, 1965, solar eclipse and the November 12, 1966, solar eclipse shows the model is capable of computing many features, including the polar plume orientations as well as radial and nonradial streamers in the solar corona. (auth)

58617 ROCKET OBSERVATIONS OF THE ULTRAVIOLET SOLAR SPECTRUM DURING THE TOTAL ECLIPSE OF MARCH 7, 1970. Gabriel, A. H. (Culham Lab., Abingdon, Eng.); Garton, W. R. S.; Goldberg, L.; (and others). Astrophys. J.; 169: No. 3, 595-614(1 Nov 1971).

A sequence of thirty-five ultraviolet photographic spectra of the Sun was obtained in the wavelength region 850 to 2190 Å, as a function of time during the eclipse. These covered the range from before second contact until midtotality, with a spatial resolution of the order 2 arc sec. A general description of the experiment and data is given. Twenty-five new coronal lines were seen, the majority of which were identified as new forbidden transitions. The $L\alpha$ corona is observed out to over 1.5 $R_{\odot}$, and a quantitative interpretation is presented. Analyses of other features—e.g., prominences, quiet-atmosphere structure, and coronal condensations—are continuing. (auth)

58618 DETERMINATION OF CORONAL POLARIZATION. Menzel, Donald H. (Harvard Coll. Observatory, Cambridge, Mass. Smithsonian Astrophysical Observatory, Cambridge, Mass.). pp 245-50 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

The problem, both theoretical and observational, of determining the distribution of brightness and polarization within the solar corona is considered. It is shown that theoretical considerations dictate that the measures of polarization must be taken in a very special manner to achieve results of highest accuracy. The basic theory is applicable generally to any problem involving studies of polarization. The observations consist of measures of apparent surface brightness of the corona as viewed through a Polaroid filter or other polarizer, with its axis set at different angles of orientation. The axis of the Polaroid is the direction of the electric vector of incident plane polarized light, for minimum transmission. (W.D.M.)

58619 SOLAR SPICULES AND CHROMOSPHERIC HEATING. Thomas, Richard N. (Joint Inst. for Laboratory Astrophysics, Boulder, Colo.). pp 331-9 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

A problem is described that involves both spectroscopic diagnostics and astrophysical aerodynamics from an atomic viewpoint. Chromospheric heating due to velocity fields associated with spicules is considered. (W.D.M.)

58620 MAPPING OF SOLAR POLARIZATION AT 7.8 GHz. Richards, D. W.; Straka, R. M. (Air Force Cambridge Research Labs., Bedford, Mass.). Nature (London) Phys. Sci.; 233: No. 40, 92-4(4 Oct 1971).

Two-dimensional maps of circularly polarized emission from the Sun at 7.8 GHz, with a resolution of 4.4 arc minutes, show polarization of local sources of up to 15% and variations as small as 2% in flux density and 0.2% in polarization, as functions of time. Both flux density and polarization in McMath plage 11002 showed substantial increases thirty minutes or more before a flare on October 24, 1970. It is suggested that flares may be triggered when both of these quantities surpass critical values. (auth) (UK)

58621 HELIUM-LIKE LINE-EMISSION CORONAL FEATURES. Acton, L. W. (Ireheed Pato Alto Research Lab., Calif.); Catura, R. C.; Meyerott, A. J.; Culhane, J. L. Nature (London) Phys. Sci.; 233: No. 39, 75-7(27 Sep 1971).

It is stated that since Gabriel and Jordan (Mon. Not. Roy. Astron. Soc., 145: 241(1969)) proposed a theory relating the relative intensity of the inter-system ($^3P-{}^1S_0$) and forbidden ($^3S_1-{}^1S_0$) lines of He-like ions to the electron density of the emitting volume, there has been increasing interest in using this type of information to determine electron densities in the solar corona. The present communication gives results of a rocket experiment designed to study the O VII and Ne IX helium-like ion line emission from discrete coronal features. These results indicate that electron densities in normal, nonflare, coronal features are below the low-density limits given by other workers for these ions. The instrumentation employed utilized two collimated Bragg crystal spectrometers covering the He-like "triplets" of O VII and Ne IX at 22 and 13.5 Å, respectively. It is concluded that the electron density in all observed coronal regions was less than $6 \times 10^9/cm^3$. Temperature estimates, obtained from the O VII/Ne IX resonance line ratios, indicate a variation between approximately 1.8×10^6 K and 2.9×10^6 K for the quiet corona and for the most intense x-ray features observed, respectively. (UK)

58622 EDDY VISCOSITY AND THE SOLAR ROTATION. Starr, V. P. (Massachusetts Inst. of Tech., Cambridge). Nature (London); 233: No. 5316, 186-7(17 Sep 1971).

It has been suggested that the deep interior of the Sun rotates faster than the visible exterior. One result would be that the departure of the mass distribution from spherical symmetry could, through its quadrupole moment, cause a contribution to the advance of the perihelion of Mercury, on the basis of Newtonian mechanics. Unless the fast interior rotation and the corresponding interior mass distribution are known, and correct allowances made, no precise check of the general relativity theory can be made on the basis of the astronomically observed perihelion advance. The question is considered as to whether some such situation concerning interior rotation can be established, or at least plausible. It has been stated that, apart from plausible magnetic complications, an equatorial acceleration in planetary and other atmospheres cannot be maintained by axisymmetric systems of motion, but requires what amounts to a negative eddy viscosity due to nonzonal disturbances in the motion and pressure. In this connection an analogy is drawn with the Earth's atmosphere. The phenomenon is sometimes called pseudo-viscosity. The whole process requires energy sources within the structure of the eddies. It is also thought possible that many stellar interiors may have a fast rotation sustained by a vertical inward angular momentum transport due to eddies. It is suggested that theoretical and numerical mathematical models be constructed that would allow for these possibilities. (UK)

Galaxies

58623 SOME COOLING PROCESSES FOR THE INTERSTELLAR MEDIUM. Voronin, A. I.; Gordeev, E; P.; Umanskii, S. Ya. (Inst. of Chemical Physics, Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 214-17(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 275-9(Mar-Apr 1971).

A calculation was made for the cross sections of transitions between the fine-structure components of C and O atoms colliding with H atoms. These transitions may play a major role in the process of cooling the interstellar medium. Exchange, dispersion, and spin-orbital interactions were taken into account in the calculation. The computed cross sections were $\approx 10^{-15}$ cm^2 for C atoms and 10^{-16} cm^2 for 0 atoms in the 100 to 1000°K temperature range. (auth)

58624 STRUCTURE OF THE RADIO SOURCE SAGITTARIUS A. Lipovka, N. M. (Central Astronomical Observatory, Pulkovo, USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 203-9(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 260-8(Mar-Apr 1971).

Observations are reported of the Sgr A region with the large Pulkovo radio telescope at $\lambda = 4$ cm (resolution $\varphi_A = 1.5 \times 90'$). Measurements in the centimeter range agree well with a thermal model for the nucleus measuring 4.5 × 10 pc. The infrared measurements at $\lambda = 1.65$ to 3.4 μ from a region 110″ across tend to support rather than disprove this model. At decimeter wavelengths (λ= 21 to 350 cm) nonthermal radiation from a region measuring 8 × 16 pc predominates. Observations in the excited-hydrogen lines, observations of OH and CH_2O in absorption, the presence of a large amount of dust, and the possibility that compact H II regions (such as feature No. 1) may occur in the nucleus all represent evidence that conditions suitable for star formation may prevail in the galactic nucleus. (auth)

58625 HOW TO FIND YOUNG GALAXIES. Sargent, W. L. W.; Searle, L. (California Inst. of Tech., Pasadena). Comments Astrophys. Space Phys.; 3: No. 4, 111-14(Jul-Aug 1971).

The criteria that might be used to identify young galaxies, supposing they exist, are discussed. By young galaxies is meant objects in our neighborhood of the Universe (within a few hundred Mpc) that have ages appreciably less than the Hubble time ($\sim 10^{10}$ years). (W.D.M.)

58626 ARE QUASI-STELLAR OBJECTS THE NUCLEI OF EMBRYONIC GALAXIES? Komberg, B. V.; Syunyaev, R. A. (Inst. of Applied Mathematics, Moscow Academy of Sciences of the USSR). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 183-6(Sep–Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 235-9(Mar–Apr 1971).

If quasi-stellar objects represent an early active evolutionary phase in the nuclei of certain types of galaxy, they might be surrounded by massive ($M \approx 10^{11}$ $M_\odot$), extended ($r \approx 30$ to 100 kpc) regions of gas, or protogalaxies, which are subsequently to disintegrate into stars. These gaseous regions, ionized by the intense ultraviolet radiation of the central source (the quasi-stellar object), might be detected from their strong radiation in narrow hydrogen recombination lines. Detailed spectroscopic or colorimetric investigations of the nebula around the quasar 3C 48 might provide an observational test of the proposed model. (auth)

58627 INSTABILITY OF WEAK IONIZATION WAVES OF D TYPE. Krasnobaev, K. V. (Inst. of Cosmic Research, Moscow). Dokl. Akad. Nauk SSSR; 196: No. 6, 1291-3(21 Feb 1971). (In Russian).

Under cosmic conditions a movement of interstellar gas often occurs that is characterized by a sharp transition from almost completely ionized hydrogen to a neutral atomic state. One may regard this transition region as the surface of a discontinuity with gas-dynamic parameters (velocity, density, temperature, degree of ionization, etc.). Mathematical relationships were developed involving the ionized front, the velocity, and other parameters, and limits were found within which must lie the ionized discontinuity of instability for a wide range of Mach numbers. (K.S.W.)

58628 ARE THE GALACTIC LOOPS SUPERNOVA REMNANTS? Berkhuijsen, Elly M.; Haslam, C. G. T.; Salter, C. J. (Leiden Observatory, NRAL, Jodrell Bank, Eng.). Astron. Astrophys.; 14: No. 2, 252-62(Sep 1971).

Observational evidence is presented on the nature of the Galactic continuum loops. Their small circle geometry is discussed. A relationship between neutral hydrogen features at intermediate and high latitudes and the continuum loops was found. A link between Loop I and the runaway star ζ Ophiucus is suggested. The available evidence would seem to favor the supernova-remnant hypothesis for the origin of the Galactic loops. (auth)

58629 OPTICAL LINE SPECTRUM OF A GAS HEATED BY HARD UV RADIATION OR ENERGETIC PARTICLES. Bergeron, J. (Cornell Univ., New York); Souffrin, S. Astron. Astrophys.; 14: No. 2, 167-88(Sep 1971).

The line emission spectrum of moderately ionized regions was calculated for cases of homogeneous heating. The heating sources considered were either hard-uv radiation (energy of order of 10^2 eV) or energetic particles (MeV protons). The physical conditions in the diffuse gas were calculated for various primary ionization rates per total hydrogen number. The ionization equilibria of hydrogen, helium, nitrogen, oxygen, and neon were determined and forbidden line as well as hydrogen and helium line emissivities were computed. The general characteristics of both heating mechanisms are given and the range of application of homogeneous heating is discussed. Observations of line intensities of nuclei of galaxies were compared with the models, and fair agreement was found for radiation heating. Furthermore, the theoretical total power radiated in the nucleus of Seyfert galaxies, mainly in the form of 200-eV photons, was computed. Good agreement with recent soft x-ray observations was found. (auth)

58630 He^+/H^+ CONCENTRATION RATIOS IN H I REGIONS. Jura, M.; Dalgarno, A. (Harvard Coll. Observatory, Cambridge, Mass. Smithsonian Astrophysical Observatory, Cambridge, Mass.). Astron. Astrophys.; 14: No. 2, 243-5(Sep 1971).

The observation of helium recombination lines in the hot intercloud medium may allow a choice between the cosmic-ray and soft-x-ray steady-state models of the interstellar medium. For an abundance ratio of helium to hydrogen of 0.1, the cosmic-ray model leads to an He^+/H^+ concentration ratio not more than 0.09 and the soft x-ray model to concentration ratios ranging from 0.15 to 0.34 for regions with fractional ionizations greater than 10^{-3}. For regions with fractional ionizations less than 10^{-3}, a radiative charge-transfer process causes very low equilibrium abundances of He^+ ions and helium recombination lines will be weak in interstellar clouds. (auth)

58631 INTERSTELLAR MATTER AND THE LOCATION OF THE SHOCK FRONT. Fahr, H. J. (Univ., Bonn). Planet. Space Sci.; 19: No. 9, 1121-9(Sep 1971).

The initially supersonic flow of the solar wind passes through a magnetic shock front where its velocity is supposed to be reduced to subsonic values. The location of this shock front is primarily determined by the energy density of the external interstellar magnetic field and the momentum density of the solar-wind plasma. Interstellar hydrogen penetrating into the heliosphere undergoes charge exchange processes with the solar-wind protons and ionization processes by the solar euv radiation. This results in an extraction of momentum from the solar-wind plasma. Changes of the geometry and the location of the shock front due to this interaction are studied in detail and it is shown that the distance of the magnetic shock front from the Sun decreases from 200 to 80 AU for an increase of the interstellar hydrogen density from 0.1 to 1.0-cm^{-3}. The geometry of the shock front is essentially spherical with a pronounced embayment in the direction opposite to the approach of interstellar matter which depends very much on the temperature of the interstellar gas. Due to the energy loss by the interaction with neutral matter the solar-wind plasma reduces its velocity with increasing distance from the Sun. This modifies Parker's solution of a constant solar-wind velocity. (auth)

58632 HYDROGEN LINE AND CONTINUUM STUDY OF MAFFEI 2 BY RADIO INTERFEROMETRY. Shostak, G. S.; Weliachew, L. (California Inst. of Tech., Pasadena). Astrophys. J.; 169: No. 2, L71-6(15 Oct 1971).

The suspected spiral galaxy Maffei 2 was interferometrically observed in the 21-cm line and adjacent continuum using a north–south baseline having a 6.5′ fringe spacing. Velocity resolution was 21 km s^{-1}. Positions of the emission centroids at each velocity allowed determination of the orientation and dynamic parameters of the object and a lower limit to the total mass. The fractional hydrogen content of Maffei 2 is less than 0.005 D, where D is the distance in Mpc. The continuum source associated with it is shown to be extended. (auth)

58633 SPECTROPHOTOMETRIC STUDY OF THE NGC 3627 GALAXY NUCLEUS FROM 3,300 TO 7,000A. Alloin, D. (Centre National de la Recherche Scientifique, Paris). Compt. Rend., Ser. B; 273: No. 1, 53-6(5 Jul 1971). (In French).

New photometric and spectroscopic results relating to the NGC 3627 galaxy nucleus are given. (France)

58634 THEORY OF THE SPIRAL STRUCTURE OF THE GALAXY. Petit, J. P. (Marseille Univ.). Compt. Rend., Ser. B; 272: No. 24, 1389-92(14 Jun 1971). (In French).

The method of perturbation is used to analyze the gravitational stability of a conglomeration of interstellar gas whose differential rotation arises from coupling with the gas of stars. Collective and local uncoupled effects are assumed, the collisions ensuring

XUM

the Maxwellian nature and isothermal conditions, the collective processes being responsible for the perturbation. The medium appears to be sensitive to a Jeans' type instability. A wave equation leading to spiral structures coherent with observation is derived. (France)

58635 MEAN RATIO OF MASS TO THE THREE-HALVES POWER OF LUMINOSITY FOR ELLIPTICAL AND LENTICULAR GALAXIES. Noonan, Thomas W. (Brockport State Coll., N. Y.). Publ. Astron. Soc. Pac.; 83: No. 494, 479-84(Aug 1971).

The available data on masses of ellipticals and lenticulars are summarized with emphasis on the uncertainties in the ratio R of mass to $10^{-0.6M}$, where M is the absolute magnitude. With correction for galactic absorption, the result is $R = 0.30^{+0.27}_{-0.14}\ \mathfrak{M}_\odot$ (and, as a by-product, a mean mass–luminosity ratio of 38^{+27}_{-16}) based on the magnitude scale in the de Vaucouleurs' catalog. The mass–luminosity relations by Poveda, Rood, and Vorontsov-Velyaminov give values of R in the same range. Implications for the mean cosmic density are discussed. (auth)

58636 STELLAR POPULATIONS IN GALAXIES. King, Ivan R. (Univ. of California, Berkeley). Publ. Astron. Soc. Pac.; 83: No. 494, 377-400(Aug 1971).

Present-day knowledge of stellar populations and the relation of populations to the forms of galaxies is reviewed. A historical outline of the concept of populations is followed by a summary of the present picture. After a discussion of the distribution of populations in the various types of galaxies, it is shown that the whole picture can be understood in terms of a simple scheme of the development of galaxies. Problems of heavy-element enrichment through nucleosynthesis are briefly discussed. The article aims at being provocative rather than definitive but retains a basically conservative point of view. (auth)

58637 MODEL OF INTERSTELLAR GRAINS WITH SURFACE ROUGHNESS. Shah, G. A.; Vardya, M. S. (Tata Inst. of Fundamental Research, Bombay). Astrophys. Space Sci.; 12: No. 1, 250-5(Jul 1971).

A simple model of surface roughness on the interstellar spherical grains was considered. A test case with dirty ice spherical grains revealed that the effect of surface roughness is to significantly enhance the extinction in the far ultraviolet compared to the equivalent smooth spheres. (auth)

58638 DIFFUSE RADIATION OF THE GALAXY IN FAR UV ACCORDING TO THE INVESTIGATIONS BY S. HAYAKAWA, K. YAMASHITA, AND S. YOSHIOKA. Rozkovskii, D. A.; Makyagin, V. S. (Astrophysical Inst., Alma-Ata, USSR). Astrophys. Space Sci.; 12: No. 1, 204-7(Jul 1971).

It has been found that certain optical properties of interstellar grains obtained by Hayakawa et al. (1969) from their study of the diffuse radiation of the Galaxy in far-uv are not in reality consistent with the more-accurate theoretical calculations of diffuse radiation for the model of the Galaxy used by Hayakawa et al. in their work. A more complex model of the Galaxy may be required for interpretation of observations in far-uv. (auth)

58639 MAP OF THE GALACTIC NUCLEUS AT 10 μm. Rieke, G. H.; Low, F. J. (Univ. of Arizona, Tucson). Nature (London); 233: No. 5314, 53-4(3 Sep 1971).

The centre of the Galaxy was scanned on Feb 15, 1971 at 10 μm using the NASA 61-inch telescope at the Catalina Observatory, with a beam of diameter 5.5 arc sec, and the scans were combined to form the map shown. Four sources could be distinguished, together with an additional broad emission zone. Some observations were also made at 2.2, 5, and 22 μm. The total flux from the galactic centre was estimated as $480 \pm 50 \times 10^{-26}$ W/m^2 Hz at 10 μM, and that at 22 μm as $2{,}300 \pm 250 \times 10^{-26}$. Some ambiguities are discussed. (UK)

58640 SIMILARITY MODELS OF INTERSTELLAR LOOP STRUCTURES. Zuzak, W. W. (Univ. of Manchester, Eng.). Astron. Astrophys.; 15: No. 1, 95-109(Nov 1971).

It is hypothesized that the interstellar loop structures are continuously driven by means of cosmic rays emitted by some source near the center. Spherical similarity solutions, in which the shock position varies with time according to $R = At^\alpha$, are obtained in the approximation that all fluid motion is radial, $u = (u_r, 0, 0)$, the magnetic field is tangential, $B = (0, 0, B_\varphi)$, and the diffusion coefficient η is zero. Any desired shell thicknesses may be obtained by considering the radiation losses to occur at the shock and thereafter treating the shocked gas adiabatically. The total energy of the shell and the rate of energy input are given by $\epsilon \sim t^{5\alpha-3}$ and $\partial\epsilon/\partial t \sim t^{5\alpha-3}$, respectively. The solutions show that the magnetic field near the contact surface at the inside of the shell is sharply peaked to a maximum value which is approximately independent of the value of the initial magnetic field. Sharp steps in the radio synchrotron emission are to be expected in scanning across such regions. Information available on Loops I and II (North Polar Spur and Cetus Arc) indicate that these have undergone relatively large cooling and are driven by a relatively small energy input. (auth)

58641 DENSITY COMPUTATION FOR THE GALACTIC MODEL OF L. PEREK. Rodionov, V. I. (Leningrad State Univ). Bull. Astron. Inst. Czech.; 22: No. 4, 162-8(1971).

The phase-space model of the Galaxy proposed by L. Perek (1966) was examined. The behavior of the density function outside the plane of symmetry of the model was studied. (auth)

58642 OBSERVATIONS OF CORE SOURCES IN SEYFERT AND NORMAL GALAXIES WITH THE WESTERBORK SYNTHESIS RADIO TELESCOPE AT 1415 MHz. van der Kruit, P. C. (Sterrewacht, Leiden). Astron. Astrophys.; 15: No. 1, 110-22(Nov 1971).

Eight Seyfert and ten normal galaxies were observed with the Westerbork Synthesis Radio Telescope at a frequency of 1415 MHz. Unresolved sources (<7″) were detected in the nuclei of all galaxies previously classified as Seyferts. Of these NGC 3077 was much weaker than the others, which is compatible with the absence of broad emission lines and NGC 4670, for which the Seyfert classification was tentative, has a nuclear source comparable to the well-established Seyferts. For two Seyfert galaxies upper limits of 5% were put on the degree of linear polarization. No radiation was detected from Markarian 205 (Weedman, 1970). In only three of the ten "normal" galaxies radio emission was detected: NGC 3310 (point-source in the nucleus), NGC 3726 (two sources symmetrically placed with respect to the nucleus), and NGC 4736 (triple source, with the middle one in the nucleus). The structure showed no evidence for relativistic effects (Ryle and Longair, 1967). The observations showed that complex structures observed in radio galaxies exist also within normal galaxies. The 1415-MHz power of the other 11th to 12th magnitude galaxies was shown to be less than about 10^{19} W Hz^{-1} sterad^{-1}. The analysis showed that there is a relation between the 1415-MHz and 10-μ power for the nuclei of Seyfert galaxies. Similar relations may exist between the powers at 1415 MHz and those in the optical continuum and H_β. This is briefly discussed in terms of the recent model given by Cavaliere et al. (1970), where the electrons radiating at radio wavelengths originate from the small core, where the infrared radiation is emitted. (auth)

58643 SMALL CLUSTERS OF GALAXIES AND THE MASS TO-LIGHT RATIO. Taff, L. G.; DeAngelis, Umberto (Univ. of Rochester, N. Y.). Astron. Astrophys.; 15: No. 1, 1-10 (Nov 1971).

The stability of 19 clusters of galaxies was investigated in an attempt to combine the virial theorem with the current mass-to-light ratios to obtain the mass distribution function for galaxies. There were 11 triplets, 4 quartets, and 4 quintets in the sample. A gross classification into Hubble classes of elliptical, spiral, and irregular showed the sample did not differ markedly from the general field. A detailed numerical analysis of possible masses for the galaxies lead to three conclusions: (1) most of these systems are probably not stable, (2) in those considered to be gravitationally bound the usual problem of high mass-to-light ratios is not encountered, and (3) current mass-to-light ratios are not statistically significant. Due to the first and third conclusions the mass distribution function could not be defined. (auth)

58644 DETERMINATION OF THE LUMINOSITY FUNCTION OF RADIO GALAXIES AT 400 AND 2700 MHz. Merkelijn, Jeannette K. (Sterrewacht, Leiden). Astron. Astrophys.; 15: No. 1, 11-29(Nov 1971).

The results of a statistical treatment of the radio galaxy identifications from the Parkes catalogue are presented. Identification statistics are also given for quasi-stellar objects. A special effort was made to minimize the errors in apparent optical magnitude and flux density. The effects of galactic absorption, limiting apparent optical magnitude, and limiting flux densities on the completeness of the samples were investigated. The resulting complete samples were used in the construction of luminosity distributions and a luminosity function at frequencies of 400 and 2700 MHz. Over the range $\log P_{400} = 23$ to 26 covered by the present investigation the luminosity function can be represented by the equation: $\log(N(\log P_{400})) = -1.06 \log P_{400} + 19.96$ where N is the number of radio galaxies per cubic megaparsec per unit interval of 0.4 in $\log P_{400}$ and P_{400} is the monochromatic power at an emission frequency of 400 MHz in WHz^{-1} sterad^{-1}. Luminosity functions were also constructed for the nearer and farther half of the observable volume. From this it was found that for $\log P_{400} > 24.4$ the density in the farther half, at $\langle z \rangle = 0.17$ was a factor two higher than in the nearer half, at $\langle z \rangle = 0.10$. This is ascribed to evolution. It is concluded that to explain the result it is necessary that at least the radio galaxy population with $\log P_{400} > 24.4$ evolves with epoch. That the low-luminosity population evolves too is unlikely in view of the 2700 MHz results. The luminosity function was found to be frequency independent for the frequencies investigated. The agreement with the results of previous investigations was satisfactory. (auth)

58645 RADIO CONTINUUM OF GALAXIES. I. OBSERVATIONS. Lequeux, J. (California Inst. of Tech., Pasadena. Observatory, Meudon, France). Astron. Astrophys.; 15: No. 1, 30-41(Nov 1971).

Positions, flux densities in the continuum near 1420 MHz, and east–west brightness distributions were measured for 54 spiral and irregular galaxies and 20 radio-weak elliptical galaxies. Upper limits for the flux density are given for 16 spiral and irregular galaxies and 7 elliptical galaxies. The observations were made with the two-element interferometer at the Owens Valley Radio Observatory. It was confirmed that the radio emission of spiral and irregular galaxies comes from a flat radio disk and/or a radio nucleus, the properties of which are discussed. NGC 5253 is an exceptional object with purely thermal radio emission. Elliptical galaxies fall into two distinct categories from their radio properties: in a given volume of space, about half of the galaxies the most powerful at high frequencies are extended and have a steep radio spectrum; the other half have a small radio diameter and a flat or complex spectrum. The latter show emission lines in their optical spectrum. (auth)

58646 RADIO CONTINUUM OF GALAXIES. II. ORIGIN OF CONTINUUM EMISSION IN SPIRAL GALAXIES. Lequeux, J. (California Inst. of Tech., Pasadena. Observatory, Meudon, France). Astron. Astrophys.; 15: No. 1, 42-9(Nov 1971).

The distribution of young population I and the distribution and rate of appearance of supernovae in the Galaxy and external spiral galaxies are compared with the diameter and distribution of the disk continuum radio in these galaxies. Marked correlations are found, and it is suggested that the relativistic electrons which produce the disk radio emission are accelerated in supernovae and propagate by diffusion in the galaxy, leaving it at about 500 pc from their source, in agreement with the model of Jokipii and Parker (1969). Radio emission in the nuclei of spiral galaxies may also be due to electrons ejected by supernovae, at least for a fraction of them. (auth)

58647 INTERSTELLAR GRAIN ALIGNMENT BY A MAGNETIC FIELD. Martin, P. G. (Inst. of Theoretical Astronomy, Cambridge, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 279-85(1971).

The role of the galactic magnetic field in the alignment of interstellar grains believed to cause optical polarization is discussed. The angular momentum of a charged grain is shown to precess about the magnetic field on a timescale less than the relaxation time of most alignment mechanisms, thus introducing the magnetic field as an important factor in many processes other than the Davis–Greenstein mechanism. The different predictions of Davis–Greenstein alignment and alignment combined with precession are presented. Recent direct observational evidence concerning magnetic alignment raises both positive support and contradictions. (auth)

58648 COMPACT GALAXIES. Fairall, A. P. (Univ. of Texas, Austin). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 383-92(1971).

An observational investigation was carried out on compact galaxies identified on the Palomar Sky Survey. Their colors and spatial distributions are discussed. Results of image tube spectroscopy, made at McDonald Observatory, of 44 compact galaxies are reported. They indicate that the majority, those redder in color, have conventional stellar spectra, while the bluer objects are of a more diverse nature. Spectra of three red compacts (obtained by Zwicky with the Palomar 200-inch telescope) are compared with spectra of conventional galaxies, and it is suggested that the high surface brightness of these compact galaxies may be accounted for by a greater proportion of high-luminosity stars. (auth) (UK)

58649 OUTWARD DRIFT OF THE INTERSTELLAR MEDIUM IN THE DISK OF THE GALAXY. Harrison, Edward R. (Univ. of Massachusetts, Amherst). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 12P-16P(1971).

It is proposed that the gaseous component in the disk of the Galaxy has an outward radial drift velocity relative to the stellar component. The drift is the result of nongravitational forces (in particular, the radial pressure gradient) acting on the gas, and the dynamic coupling (mainly due to mass exchange) between gas and stars. The gas flow has trailing spiral streamlines relative to the stars. It is estimated that at the Sun's distance from the galactic center the radial velocity is 0.5 km s^{-1}, and the tilt of the spiral streamlines is 10°. Some comments are made on the possible importance of the motion concerning the origin of spiral structure. (auth) (UK)

58650 SPECTRUM AND GALACTIC ISOTROPY OF DIFFUSE COSMIC X RAYS. Davison, P. J. N.; Thomas, R. M. (Univ. of Adelaide). Nature (London) Phys. Sci.; 233: No. 37, 27-9(13 Sep 1971).

Measurements are reported of the spectrum of the diffuse cosmic x-ray background, together with estimates of the isotropy of the background with respect to galactic latitude, and an upper limit for a line source of x rays along the galactic equator, using a balloon-borne detector launched from Mildura, Australia on Feb. 29, 1968. Background x rays as measured by balloon-borne x-ray telescopes are a mixture of those of atmospheric origin, of spurious counts due to imperfect shielding of the detector, and of genuine cosmic x rays, and the method of obtaining the latter is described and the spectrum obtained is shown. A galactic latitude survey was carried out and the data analyzed for the energy range 26 to 67 keV, excluding regions of the sky containing resolved discrete sources. The anisotropy factor obtained was $\alpha = 17.5 \pm 9.5\%$. The observations were interpreted in terms of an upper limit for α and are not regarded as the result of a diffuse flux. The results may be presented in terms of a derived line flux in the galactic plane rather than in terms of α, and values for this are shown graphically. (UK)

58651 ABSORPTION-LINE STUDY OF THE GALACTIC NEUTRAL HYDROGEN AT 21 CENTIMETERS WAVELENGTH. Hughes, M. P.; Thompson, A. R.; Colvin, R. S. (Stanford Univ., Calif.). Astrophys. J., Suppl. Ser.; 23: No. 200, 323-67(Oct 1971).

The interferometer at the Owens Valley Radio Observatory, together with a multichannel receiving system with filters of bandwidth 4 or 6 kHz, was used to observe ninety-seven sources for absorption at 21-cm wavelength. All but four of the sources were believed to be extragalactic. Measurable absorption was detected in sixty-four cases, and for these the profiles are presented. Optical depths greater than 0.5 were found only within 20° of the galactic plane, except in the region of the Cetus Arc where values up to 1.4 occur near $b = -40°$. The highest galactic latitude at which absorption was detected was 75° for Vir A. Upper limits for the optical depths of two intermediate-velocity clouds near $b = 40°$ were 0.02 and 0.06. The mean temperature of the cool absorbing gas was found to be 71 ± 9°K, and this figure was corrected for the effects of the surrounding hot gas. The highest lower limit for the temperature of the hotter gas was ~600°K. There was also some evidence of temperatures of a few hundred degrees Kelvin. On the assumption that the interstellar gas has a two-temperature structure, an analysis was made to determine the fraction of the neutral atomic hydrogen in the cool state. For a line of sight close to the galactic plane, a figure of about 75% was obtained. For the general vicinity of the Sun, the result was 36 to 45%, depending upon the temperature ratio of the two states of the gas, and this was probably also a good estimate for the whole galaxy. A comparison of 21-cm absorption with published measurements of the free–free absorption for three of the sources resulted in a mean value for the ionization rate of 2.0×10^{-15} s^{-1}. This figure referred to gas in the cool state and within 2 kpc of the Sun. The distance of the excess absorbing gas in the direction of Cetus Arc was found to be ≤120 pc from a comparison of velocities of 21-cm absorption features with those of absorption lines in nearby stars. For the galactic source 3C 58, a lower limit of 8.5 kpc was obtained for the distance. (auth)

58652 NEUTRAL HYDROGEN IN AN INTERIOR REGION OF THE GALAXY. THE LONGITUDE INTERVAL 22^0 TO 42^0. I. OBSERVATIONS. Shane, W. W. (Leiden Observatory). Astron. Astrophys., Suppl. Ser.; 4: No. 1, 1-42(Aug 1971).

Measurements of the 21-cm hydrogen emission near the galactic plane were made using the 25-m telescope in Dwingeloo. The region $l = 22.3$ to 42.3° was surveyed at 1° intervals in longitude, with an extent to between 6 and 9° on either side of the galactic equator. The observing and reduction procedures are described briefly. The observations consist in line profiles and

XUM

latitude scans. The reduced measurements are reproduced graphically. (auth)

58653 NEAR-ULTRAVIOLET SURFACE PHOTOMETRY OF THE SOUTHERN MILKY WAY. Pfleiderer, J. (Univ., Bonn); Mayer, Ursula. Astron. J.; 76: No. 8, 691-700(Oct 1971).

Isophote maps are presented of the Milky Way (except the northern region from Per to Cep/Cyg): color — U of the UBV system; field of view — ~1 deg^2; resolution — 1 to 2°. The mean intensity of the inner Milky Way is about 100 S_{10}(U) [intensity at poles 15 to 20 S_{10}(U)]. The brightest areas, with intensities up to several hundreds S_{10}(U), are in Sgr/Sco, Car, Vel/Pup, and Cyg. Most bright areas coincide with OB associations and extended Hα regions, and many other such objects are clearly visible, probably due to Balmer continuum emission. The reduction procedure is described in detail. (auth)

58654 PHOTOMETRIC MEASUREMENTS AT $\lambda = 11$ μm OF NGC 4151. Stein, W. A.; Gillett, F. C. (Univ. of California, San Diego). Nature (London) Phys. Sci.; 233: No. 36, 16-18(6 Sep 1971).

The results presented arise from data accumulated over the period June 1969 to June 1971 with a view to investigating the possible variability of NGC 4151 in regard to infrared radiation. It appeared that variations on short time scales ($\leq$1 month) occurred at various times during the course of the observations, although it is recognised that such observations could be misleading on a short time scale. It is concluded that, in spite of the fact that sometimes it has appeared that changes of flux level have occurred on short time scales, if all measurements are included no flux changes can be conclusively shown to be outside of a normal statistical dispersion of results. (UK)

58655 INTERPRETATION OF THE Hα PROFILE OF THE SEYFERT GALAXY NGC 5548. Anderson, Kurt S. (Harvard Coll. Observatory, Cambridge, Mass.). Astrophys. J.; 169: No. 3, 449-53(1 Nov 1971).

Spectroscopic observations of the Hα profile in the Seyfert galaxy NGC 5548 suggest that electron scattering is not the dominant factor in producing the extensive emission wings. The profile shows indications of discrete cloud structures. The predictions of a simple model based upon radial expansion about an optically thick central region are compared with the observations. (auth)

58656 COLLECTIVE INSTABILITIES AND WAVES FOR INHOMOGENEOUS STELLAR SYSTEMS. II. THE NORMAL MODES PROBLEM OF THE SELF-CONSISTENT PLANE-PARALLEL SLAB. Mark, James W.-K. (Massachusetts Inst. of Tech., Cambridge). Astrophys. J.; 169: No. 3, 435-75(1 Nov 1971).

Studies were made of the normal modes of instabilities and waves for models of inhomogeneous, nonrotating stellar systems whose basic equilibrium has one-dimensional planar symmetry (slabs) while the perturbations are not restricted to this symmetry. Comparisons were also made with gaseous slabs, the energy principle, and the Hartree–Fock operator principle. The perturbations separate into modes even and odd in the spatial coordinate parallel to the density gradient. For even modes, the gravitational instability was isolated under more general conditions than in a previous derivation that used the energy principle. A two-stream instability was identified at long wavelengths as an even mode. Bending-type odd modes were also found. For nearly isotropic velocity distributions, this bending mode is a propagating, neutral (or slightly damped) wave, while for large velocity anisotropies, the Kelvin–Helmholtz (fire-hose) instability is recovered. For initial-valued problems involving this inhomogeneous equilibrium, each of these modes gives a pole singularity in the Laplace transform of the time behavior. (auth)

58657 DYNAMIC EQUATION FOR STOCHASTIC MAGNETIC FIELD LINES IN THE GALAXY. Jones, Frank C. (Goddard Space Flight Center, Greenbelt, Md.). Astrophys. J.; 169: No. 3, 477-85(1 Nov 1971).

It has been pointed out by previous authors that the turbulent motion of the ionized interstellar gas will cause a given line of force of the galactic magnetic field to wander in a random manner even though the average field may be quite regular. An equation is derived that describes the development of the probability density of a given field line as a function of distance along the average field. It is explained why a Fokker–Planck type of equation is quite unsuitable in this case and it is shown that the answer must be sought in the theory of stationary Gaussian processes. The distribution function for the "endpoints" of a field line that starts on the galactic central plane is also derived. Endpoint in this context means the point where the field line first wanders so near the surface of the galactic disk that it can no longer confine cosmic rays. (auth)

58658 SPECTRUM OF AP LIB (PKS 1514-24). Rodgers, A. W. (Australian National Univ., Canberra). Nature (London) Phys. Sci.; 233: No. 39, 75(27 Sep 1971).

The rapid and erratically variable AP Lib was identified with the radio source PKS 1514-24. It appears to have no emission lines between 6500 and 4300 Å, and has been classified as an N galaxy. The similarity between AP Lib and BL Lac is discussed, and spectra of AP Lib are described, obtained in August 1971 with the 74-inch telescope at Mount Stromlo Observatory. The image of AP Lib was observed to be stellar when the seeing image was less than 1.5 arc s in diameter, supporting the classification of AP Lib as an N-type galaxy. It was apparent from the energy distribution in the continuous spectra that AP Lib, at the time observed, possessed a marked uv excess relative to stars of similar blue-visual gradient, in agreement with the photometry of PKS 1514-24, and indicating a marked spectrophotometric similarity between AP Lib and BL Lac. (UK)

Cosmology

58659 COUNTS OF SOURCES AND THEORIES. Brecher, K.; Burbidge, G.; Strittmatter, P. A. Comments Astrophys. Space Phys.; 3: No. 4, 99-110(Jul-Aug 1971).

If any class of extragalactic object is distributed uniformly in space, counts to successively increasing metric distance, and hence to fainter apparent brightness will give numbers proportional to the volumes. The method has been applied extensively to extragalactic radio sources. Topics considered in some detail include interpretations of the log N–log S curve for bright sources, possible interpretations of the counts of fainter sources, and isotropy of the source counts and the background radiation. (W.D.M.)

58660 LOCALIZABILITY OF PARTICLES IN DE SITTER SPACE. Hannabuss, K. C. (Mathematical Inst., Oxford). Proc. Cambridge Phil. Soc.; 70: 283-302(1971).

Motivated by the Iwasawa decomposition and its geometrical interpretation, two new decompositions of the de Sitter group are obtained. The first is applied to construct the representations of the de Sitter group in a form immediately comparable with those of the Poincaré group. In particular, they act on functions over an hyperboloid like the momentum hyperboloid of the Poincaré group, although they require both positive and negative mass shells of that hyperboloid. Using the second decomposition it is shown that the representations of the de Sitter group are localizable in the sense of Mackey and Wightman. Position operators are exhibited. (auth)

58661 COSMICAL CONSTANT. McCrea, W. H. (Univ. of Sussex, Brighton, Eng.). Quart. J. Roy. Astron. Soc.; 12: No. 2, 140-53(Jun 1971).

Ever since the beginning of relativistic cosmology the cosmical constant has in one way or another played a prominent but ill-understood part. It makes its appearance in general relativity as allegedly a universal constant, awaiting both a meaning and a value, in a theory that seemingly ought by its nature to involve no universal constants. This situation is reviewed. The tentative conclusion is reached that, if general relativity is to be treated as a self-contained theory, then the "cosmical terms" that contain the cosmical constant should be omitted. But if general relativity is treated as only a part of what is needed to construct a theoretical model of physical reality, then the cosmical terms ought to be retained as affording additional freedom in linking up with other parts of physical theory. In that case, it seems reasonable to expect that the cosmical constant may have to be assigned different values in different applications of the theory. So far as relativistic cosmology is concerned, the pragmatic treatment of the cosmical constant implicitly employed at the present time by most cosmologists seems to be entirely reasonable, although there is still no accepted cosmological value of the constant. (auth)

58662 MEASUREMENT OF THE GRAVITATIONAL DEFLECTION OF RADIO WAVES BY THE SUN. Hill, J. M. (Mullard Radio Astronomy Observatory, Cambridge, Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 7P-11P(1971).

The deflection of radio waves in the Sun's gravitational field was measured by using the Cambridge One-Mile telescope to observe the radio source 3C 279 before and after its occultation by the Sun on October 8, 1970. The observed deflection was 1.07 ± 0.17 times that predicted by general relativity. (auth) (UK)

58663 TIME SCALE OF EXPANSION FOR COSMOLOGICAL MODELS WITH RADIATION. Edwards, D. (Univ. of Liverpool). Mon. Notic. Roy. Astron. Soc.; 153: No. 3, 17P-20P(1971).

Exact expressions are derived in terms of the basic parameters for Friedmann models containing noninteracting matter and radiation. (auth) (UK)

58664 DECISIVE TEST FOR GENERAL RELATIVITY. Blokland, A. Astrophys. Space Sci.; 12: No. 1, 219-42(Jul 1971).

A very accurate evaluation of the Schwarzschild constants is now possible from continuous observation of the spin axes of coupled gyroscopes because the angular velocities of these axes can be more than 100,000 times greater than the better-known precession velocity of a single gyro in orbit around the Earth. This enormous increase in velocity is a consequence of a gravomagnetic effect in gravitational interaction that resembles the electromagnetic effect in electrical interaction. (auth)

58665 SPIN STATE OF ATOMS AND MOLECULES IN A COSMIC MEDIUM. Varshalovich, D. A. (Ioffe Inst. of Physics and Tech., Leningrad). Usp. Fiz. Nauk; 101: 369-83(Jul 1970). (In Russian).

Nonequilibrium dynamic (in contrast to equilibrium static) orientation of particle spins must be a very widespread phenomenon in the Universe. The spins of particles align mainly as a result of oriented streams of nonpolarized radiation that proceeds from stars and nebula. The alignment of spins leads to change of transparency of the medium for resonance radiation. This phenomenon essentially has to be considered, for information purposes, for all resonance radiation passing through the cosmic medium. The calculation of alignment not only can give corrections to partial densities of particles, but permits qualitative determination of the direction of the magnetic field and anisotropy of streams of radiation in the medium. 41 references. (tr-auth)

58666 WAS THERE REALLY A BIG BANG? Burbidge, G. (Univ. of California, San Diego). Nature (London); 233: No. 5314, 36-40(3 Sep 1971).

It is stated that evidence in favor of a "big-bang" cosmology is much less definite than often realized, and it is not impossible that we are living in a steady-state Universe. After a general introduction to the subject the following are discussed: determination of the deceleration parameter, redshifts of faint sources, corrections for evolution, the Stebbins–Whitford effect, counts of radio sources, volume effect or luminosity evolution, QSOs, microwave background radiation, and nucleosynthesis and the origin of galaxies. 79 references. (UK)

58667 ON THE NATURE OF MASS. Hoyle, F.; Narlikar, J. V. (Cambridge Univ., Eng.). Nature (London); 233: No. 5314, 41-4(3 Sep 1971).

It is stated that the increasing number of observations of discrepant redshifts means that no longer can these be passed off as chance juxtapositions. A possible explanation of the data is given in terms of a theory that incorporates a gravitational "constant" that is decreasing with time. (auth) (UK)

58668 FRAGMENTATION OF SUPERMASSIVE DISKS. Salpeter, E. E. (Cornell Univ., Ithaca, N. Y.). Nature (London) Phys. Sci.; 233: No. 36, 5-7(6 Sep 1971).

Supermassive rotating disks, invoked by some models for quasars and active nuclei of galaxies, are unstable against fragmentation. A hierarchy of successive fragmentation into smaller and smaller pieces is described. Questions are raised about pulsar-like and gravitational radiation, which become important at the later stages of fragmentation. (auth) (UK)

58669 QUALITATIVE COSMOLOGY. Collins, C. B.; Stewart, J. M. (Cambridge Univ., Eng.). Mon. Notic. Roy. Astron. Soc.; 153: No. 4, 419-34(1971).

The role of dissipative processes in the early Universe, in accordance with the "chaotic cosmology programme" outlined by Misner is discussed. The conclusions drawn are that (i) for arbitrary initial conditions the shear anisotropy could be arbitrarily large now; (ii) the Universe need not have been in thermal equilibrium during the early stages; and (iii) matter effects are unimportant in most, but not all, of the cosmological models considered. These results are valid for a moderately large class of nonrotating spatially homogeneous cosmologies, and so considerably extend the earlier work of Stewart. (auth) (UK)

58670 PROCEEDINGS OF THE INTERNATIONAL CONFERENCE ON THERMODYNAMICS, CARDIFF, WALES, 1–4 APRIL 1970. Pure Appl. Chem.; 22: No. 3-4, 429-500(1970). (CONF-700446).

The conference papers were divided into six sections, of which one, statistical thermodynamics in Astrophysics and Relativity, was within the scope of NSA. This section comprised seven papers for which separate abstracts were prepared. (UK)

For abstracts of individual papers see: 58520, 58521, 58671–58674, and 59238.

58671 TIME ASYMMETRY IN ELECTRODYNAMICS AND COSMOLOGY. Narlikar, J. V. (Cambridge Univ., Eng.). Pure Appl. Chem.; 22: No. 3-4, 449-56(1970).

From International conference on thermodynamics; Cardiff, Wales (1 Apr 1970).

The concept of the "arrow of time" is discussed in relation to thermodynamics, electrodynamics, and cosmology. Time symmetric electrodynamics, the absorber theory of radiation, and quantum transitions are discussed and a working theory developed applicable to a Universe with a perfect future absorber and an imperfect past absorber, such as the steady state cosmological model. It is stated that the approach adopted establishes a strong connection between the electrodynamic and cosmological arrows of time, and points a way toward linking these arrows with the thermodynamic one. (auth) (UK)

58672 COSMIC EVOLUTION AND THERMODYNAMIC IRREVERSIBILITY. Layzer, David (Harvard Univ., Cambridge, Mass.). Pure Appl. Chem.; 22: No. 3-4, 457-68(1970).

From International conference on thermodynamics; Cardiff, Wales (1 Apr 1970).

Three macroscopic arrows of time are discussed: the thermodynamic arrow, defined by entropy-generating processes in closed systems, the historical arrow, defined by information-generating processes in certain open systems, and the cosmological arrow, defined by the cosmic expansion. (auth) (UK)

58673 CARNOT CYCLES FOR GENERAL-RELATIVISTIC SYSTEMS. Ebert, R. (Univ., Wuerzburg, Ger.). Pure Appl. Chem.; 22: No. 3-4, 481-6(1970).

From International conference on thermodynamics; Cardiff, Wales (1 Apr 1970).

A generalization of ordinary Carnot cycles is given for thermodynamic systems with stationary gravitational fields. The two heat reservoirs are assumed to be located at different points in space. In addition to the standard change of thermodynamic quantities the Carnot engine is allowed to change its position during the cycle. A "generalized Carnot cycle" is then defined by the following process: (1) Connection of the Carnot engine with the first heat reservoir (exchanging heat), (2) Change of position of the Carnot engine from the first to the second heat reservoir, (3) Connection of the Carnot engine with the second heat reservoir (exchanging heat), (4) Change of position of the Carnot engine from the second to the first heat reservoir, after which the cycle repeats. In all changes of position the presence of the gravitational field has to be considered. The special case of an ordinary Carnot cycle is obtained when there is no gravitational field or when the heat reservoirs are located at the same point. Under the assumption that gravitation can be described by general relativity the efficiency of these generalized Carnot cycles is calculated for stationary fields. Thermodynamic equilibrium exists when the efficiency of a generalized Carnot cycle operating between any two parts of the system is zero. For this case it is found that $T \cdot \|\xi\|$ is a constant independent of position. As used here T is the ordinary thermodynamic temperature and $\|\xi\|$ denotes the norm field of the Killing vector field ξ, representing the stationarity of the gravitational field. The proof is independent of the field equations of general relativity. Consequently equilibrium consists of a temperature field which depends on the gravitational field. For static fields with spherical symmetry Tolman has proved this relation by using the field equation of general relativity. The results show that this relation holds quite generally for arbitrary stationary fields. (auth) (UK)

58674 VARIATIONAL FORMULATION OF RELATIVISTIC FLUID THERMODYNAMICS. Schmid, L. A. (Goddard Space Flight Center, Greenbelt, Md.). Pure Appl. Chem.; 22: No. 3-4, 493-500(1970).

From International conference on thermodynamics; Cardiff, Wales (1 Apr 1970).

As a first step toward generalizing reversible thermodynamics from the case of a homogeneous system to that of a system whose local velocity may be a function of its position in space–time, a variational principle is derived for relativistic reversible adiabatic flow of a compressible fluid. This variational principle yields the correct form of the stress–energy tensor for reversible adiabatic flow of a compressible fluid (together with the necessary statements of particle and entropy conservation), and automatically gives the expression for the solution of Euler's equation of motion for the fluid in terms of the four-gradients of the generalized coordinates. 58675 PHASE DIAGRAMS OF HYDROGEN AND HELIUM. Trubitsyn, V. P. (Inst. of Geophysics, Moscow). Sov. Astron. AJ (Engl. Transl.); 15: No. 2, 303-9(Sep-Oct 1971).

Translated from Astron. Zh.; 48: No. 2, 390-8(Mar-Apr 1971).

The thermodynamic properties and phase diagrams of hydrogen and helium are discussed for pressures found in the interiors of Jupiter and Saturn. (auth)

58676 IONOSPHERE OF MARS BELOW 80 km ALTITUDE. II. SOLAR COSMIC-RAY EVENT. Whitten, R. C. (Ames Research Center, Moffett Field, Calif.); Poppoff, I. G.; Sims, J. S.; (and others). Planet. Space Sci.; 19: No. 8, 971-9(Aug 1971).

Models of the lower ionosphere of Mars during a solar proton event are developed using ion chemistry previously proposed (1970). The computed electron number densities for two representative proton spectra appear to be large enough to easily allow the determination of the entire profiles of electron concentration by means of a bistatic radar occultation experiment. (auth) (UK)

58677 NEW MOON: A VIEW. Hinners, N. W. (Bellcomm, Inc., Washington, D. C.). Rev. Geophys. Space Phys.; 9: No. 3, 447-522(Aug 1971).

New Moon data from Apollo 11, 12, and 14 and Luna 16 allows detailed analyses to be made of lunar data. It appears that the Moon originated about 4.6 b.y. ago, as did the Earth and meteorites, thus at the beginning of the solar system. The igneous processes that resulted in flooding of the mare basins with basaltic lavas are now understood, as are the effects of meteoroids in generating the shallow surficial soil or regolith. Other lunar materials studied include breccias, anorthosites, Kreep, mesotasis, granitic materials, lunar carbon, organic matter, tektites, meteorites, "life", and Rock 12013. Discussions on lunar chronology, lunar-surface processes, and global aspects of the moon are given featuring the latest data. Noble gases in lunar soil are known to be of solar-wind origin. 212 references. (J.C.W.)

58678 LUNAR ROCKS. Mason, Brian. Sci. Amer.; 225: No. 4, 49-58(Oct 1971).

Results from studies of Apollo 11, 12, and 14, and Luna 16 samples are reviewed. Topics considered include classification, mineralogy, texture, significance of the findings, and volcanism on the Moon. (W.D.M.)

58679 LUNAR ATMOSPHERE. Johnson, Francis S. (Univ. of Texas, Dallas). Rev. Geophys. Space Phys.; 9: No. 3, 813-23 (Aug 1971).

A rarefied atmosphere should be present on the moon because of contributions from the solar wind, meteoric volatilization, and internal degassing. Transient contributions to the atmosphere must be produced by rocket gases during lunar missions. These gases may obscure the ambient atmosphere in the vicinity of the landing site for a period of several months after a lunar landing. Of the three natural sources, definite predictions can be made only on the basis of solar-wind input. The lunar atmosphere of solar origin is expected to consist mainly of neon; lighter gases are less prevalent because of their more rapid thermal escape and are less prevalent because of their lesser concentrations in the solar wind. Daytime neon concentrations are expected to be near 6×10^4 cm^{-3}, and nighttime concentrations are expected to be near 1.5×10^6 cm^{-3}. 26 references. (auth)

58680 DISTRIBUTION OF ^{222}Rn ON THE SURFACE OF THE MOON. Heymann, D.; Yaniv, A. (Rice Univ., Houston, Tex. Tel Aviv Univ, Israel). Nature (London) Phys. Sci.; 233: No. 37, 37-9(13 Sep 1971).

It is believed that the considerations discussed may have interesting implications for the α-spectrometry experiments planned for the command module of the later Apollo flights. The most important of these considerations is the sticking time, τ, of ^{222}Rn atoms on regolith materials. If τ is much greater than about 10^2 s, then ^{222}Rn cannot migrate far from its point of release, since it will be strongly adsorbed on the surface. If, however, τ is much smaller than 10^2 s, no adsorption occurs and ^{222}Rn will become more or less uniformly distributed across the entire Moon. The value of τ for ^{222}Rn on regolith material has not been measured and it is difficult to estimate it accurately. The conditions required to produce either a uniform ^{222}Rn distribution or a ^{222}Rn pile-up are considered. Strong adsorption of ^{222}Rn on the sunlit side is considered very unlikely, but pile-ups may be expected to occur at the terminator. A simple model is suggested. It is considered that detailed analysis of the experimental data from the Apollo flights may provide a reasonably accurate value for the heat of adsorption of Rn on regolith material, which is needed for calculating Rn diffusion and escape from the regolith itself, which in turn has implications for U, Th–Pb dating of lunar samples. Atomic and Molecular Physics

58681 EMISSION OF SLOW POSITRONS FROM DIELECTRIC ABSORBERS, STATISTICAL VARIATIONS IN THE ELECTROSTATIC POTENTIAL MEASURED OUTSIDE OF A REAL CONDUCTING SURFACE AND STIMULATED EMISSION OF MAGNETIC BREMSSTRAHLUNG. Madey, John Michael Julius. Stanford, Calif.; Stanford Univ. (1971). 206p. University Microfilms Order No. 71-19,724.

Thesis.

Part I summarizes the background and analyzes the results of a survey designed to detect the emission of low-energy positrons from mica and polyethylene absorbers irradiated by the energetic positrons from a millicurie level ^{58}Co source. A measurable flux of slow positrons was found to be emitted from a polyethylene absorber whose crystallite structure had been preferentially oriented relative to the surface. In Part II, an analysis is presented of the statistical properties of the electrostatic potential and the electric field outside of a real conducting surface due to the random exposure at the surface of crystal planes with differing work functions. Two cases are considered, corresponding to the potential measured outside of a conducting cylindrical tube. Taking the boundary conditions explicitly into account, expressions are developed for the first and second moments of the potential and the field. In Part III, the Weizsäcker–Williams method is used to calculate the gain due to the induced emission of radiation into a single electromagnetic mode parallel to the motion of a relativistic electron beam through a periodic transverse dc magnetic field. Finite gain is available from the far-infrared through the visible region, raising the possibility of continuously tunable amplifiers and oscillators at these frequencies with the further possibility of partially coherent radiation sources in the ultraviolet and x-ray regions to beyond 10 keV. Several numerical examples are considered. (TSS) (Diss. Abstr. Int., B)

58682 TOPICS IN MODERN PHYSICS: A TRIBUTE TO EDWARD U. CONDON. Brittin, Wesley E.; Odabasi, Halis (eds.). Boulder, Colo.; Colorado Associated University Press (1971). 391p. $17.50.

The twenty-two papers of this volume were prepared as a tribute to Prof. E. U. Condon by his associates on the occasion of his becoming professor emeritus in the Department of Physics, Univ. of Colorado, in the summer of 1970. The collection covers a wide range of topics, reflecting the many different areas of physics actively studied by Condon. An individual abstract was prepared for the twelve papers in scope for NSA. (L.M.T.)

For abstracts of individual papers see: 58618, 58619, 58715–58718, 58815, 58816, 59234, 59235, 59447, and 59793.

Atomic, Electron, Ion, and Molecular Beams and Their Reactions

58683 (FRNC-TH-49) SECONDARY ELECTRON EMISSION FROM GERMANIUM UNDER ELECTRON BOMBARDMENT. Touzillier, Lucien (Toulouse Univ. (France). Faculte des Sciences). 1970. 110p. (In French). Dep. NTIS (U. S. Sales Only).

Thesis.

Secondary emission from platinum was briefly studied. A more detailed investigation of secondary emission from germanium was then made using the target temperature as a parameter. The influence of the target temperature on secondary emission from metals and semiconductors was studied, and an attempt was made to obtain information on the secondary-emission mechanism. An attempt was also made to relate this secondary emission to the structure of the solid by means of electronic transitions. A comparison was made between the results obtained and those associated with photoemission, the analogy between discrete energy losses from a beam of electrons and optical spectra being well established. (France)

58684 DETERMINATION OF PHOTOIONIZATION CROSS SECTIONS IN VARIOUS ATOMIC MODELS. Combet-Farnoux, F. (Univ., Paris). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.203-9(Nov-Dec 1970). (In French).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

It is shown that a single-electron model with a central potential is sufficient to account for the existence of a resonance maximum, near the ionization threshold, in the cross sections of certain subshells. The amplitude and position of this maxima vary with Z. A comparison is made between σ_{4d} values obtained using two different central potentials (Herman and Skillman potential and McKlapischs parametric potential). It is also shown how a simple model with a central potential can be used to introduce core relaxation in the atom after ionization, exchange effects between the ejected electron and the core, and certain correlation effects (interchannel interactions). (auth) (France)

58685 DEPTH DISTRIBUTION OF CHARACTERISTIC X-RAY PRODUCTION IN COPPER BY 12- TO 30-keV ELECTRONS. Duerr, G.; Hofer, W. O.; Schulz, F.; Wittmaack, K. (Institut fuer Strahlenschutz, Munich). Z. Phys.; 246: No. 4, 312-22 (1971). (In German).

The depth distribution of characteristic x-ray production in copper by 12- to 30-keV electrons was measured with a zinc tracer. The results are examined in terms of characteristic distribution parameters, which show a potential-law energy dependence. Reduction of the depth data and the electron energies by means of electron range and excitation energy, respectively, allows comparison with experimental and theoretical results of other authors on various target—tracer combinations. Although a general energy dependence is found for the majority of the reduced characteristic parameters, the accuracy of the data is not satisfying. Some of the measured distributions obviously contain large systematic errors. (auth)

58686 TRANSITION RADIATION AND OPTICAL PROPERTIES OF EVAPORATED CARBON FOIL. DiNardo, R. P.; Goland, A. N. (Brookhaven National Lab., Upton, N. Y.). J. Opt. Soc. Amer.: 61: No. 10, 1321-4(Oct 1971).

The light emitted from an electron-irradiated self-supported foil (334 ± 30 Å) of evaporated carbon was investigated experimentally. Normally incident 1-μA electron beams having monochromatic energies of 297, 423, 632 keV, and 1.10 MeV were used. These correspond to β^2 values of 0.6, 0.7, 0.8, and 0.9, respectively, where $\beta = v/c$, and v is the velocity of the incident electrons. The absolute photon intensity emitted in the 2200 to 5800-Å spectral region was measured with a calibrated optical system. The results were analyzed with respect to wavelength of emitted radiation, forward angle of emission, θ (15° and 30°), and degree of polarization (parallel and perpendicular to the plane of the incident electrons and observed light). The transition-radiation contribution determined from the parallel-polarized component was compared with the generalized theory of Ritchie and Eldridge, using the optical constants of graphite and glassy carbon. From this comparison and a best-fit calculation, the optical constants for the carbon film throughout the 2200 to 5800-Å spectral region were derived. The derived constants indicate that the carbon film has optical properties between those of graphite and glassy (amorphous) carbon. The results obtained stress the importance of measuring the optical constants of a given carbon film for any experiment in which they are needed. (auth)

58687 SCATTERING OF POLARIZED ELECTRONS FROM MAGNETIC MATERIALS. Vriens, L. (Philips Research Labs., Eindhoven, Netherlands). Phys. Rev., B; 4: No. 9, 3088-93 (1 Nov 1971).

Cross-section formulas for large-angle (e,e) and for coincidence (e,2e) scattering of fast electrons from gaseous and solid targets are derived. It is shown that the momentum- and spin-density distribution of the bound electrons can be obtained from single (e,e) scattering of polarized electrons. It is also shown that the electronic spin- and energy-dependent momentum-density distribution can be obtained from (e,2e) scattering of polarized electrons. An (e,2e) experiment with unpolarized electrons gives the energy-dependent momentum distribution. A comparison is made with related methods, like Compton scattering, and the feasibility of the suggested experiments is discussed. (auth)

58688 APPROXIMATE SOLUTION OF A BOUNDARY-VALUE PROBLEM FOR AN ELECTRON CURRENT IN CROSSED FIELDS. Mikulin, A. I. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 538-41(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 687-91(Apr 1971).

Neutralization of ion space charge by an electron beam in crossed magnetic and electric fields is considered. The problem is put into a form suitable for approximate solution by substitution of variables and functions for the case in which the potential variation in the space between the electrodes is monotonic. (auth)

58689 LOW-ANGLE SCATTERING OF ENERGETIC IONS FROM AN AMORPHOUS SURFACE. Marwick, A. D.; Thompson, M. W.; Farmery, B. W.; Harbinson, G. S. (Univ. of Sussex, Brighton, Eng.). Radiat. Eff.; 10: No. 1-2, 49-54(Jul 1971).

Ions of hydrogen and helium at 275 keV were scattered from a flat surface composed of amorphous tungsten oxide prepared by anodization. Measurements of the angular distribution and the energy spectrum were conducted for various angles of incidence and angles of scattering up to 5°. The observations are compared with the predictions of a plural scattering theory and good agreement is found. In particular, the most probable energy loss of the scattered ions is proportional to the scattering angle, the angular distribution of ions scattered with any particular energy loss is roughly a gaussian function truncated by the surface plane while the energy spectrum has nearly the predicted form of a skewed peak. (auth)

58690 INTERACTION OF GAS ATOM WITH A HOT SOLID SURFACE: HARMONIC-MODEL ANALYSIS. Forman, R. E. (Brown Univ., Providence). J. Chem. Phys.; 55: No. 6, 2839-48(15 Sep 1971).

The interaction of a monoenergetic gas beam with a hot surface is viewed as a collection of discrete two-body collisions. By use of a soft-cube model with a truncated harmonic interaction potential, the interaction is reduced to a linear problem. The solution to this simplified view indicates that an important role of thermal motion of the solid atoms is reflected in the distribution of their initial conditions at the time interaction begins. Specifically, the initial-condition distribution is biased toward interactions beginning with greater than average relative velocity between gas and solid atoms. The average exit velocity of the gas is expressed as an integral over the initial-condition distributions. This integral cannot be evaluated exactly in closed form and an approximate analytical evaluation is obtained. A computer simulation of the problem was devised and shows satisfactory agreement with the theoretical value for the average relative velocity at the start of interaction and the analytical approximation for the average gas exit velocity. (auth)

58691 FORMATION AND LORENTZ IONIZATION OF HIGHLY EXCITED ATOMS. Il'in, R. N. (Ioffe Inst. of Physics and Tech., Leningrad). pp 113-32 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Properties of highly excited atoms and mechanisms of ionization in electric fields are reviewed. Methods of production of highly excited atoms are surveyed. Emphasis is on charge-transfer processes; results for various gaseous and metal-vapor targets are compared. 27 references. (A.G.W.)

58692 NONRADIATIVE PROCESSES AT SOLID SURFACES. Hagstrum, H. D. (Bell Telephone Labs., Murray Hill, N. J.). pp 190-210 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Electronic transition processes that occur in a system of a solid and an atomic particle when the particle is slowly approaching the solid surface are reviewed. The two-electron Auger processes and the resonance processes that can act as precursors to them are discussed in terms of electron-energy and potential-energy diagrams. The current state of knowledge of the Auger ejection process is summarized by a series of questions and answers. An experimental method for study of ion neutralization at solid surfaces is described briefly, and a few typical results are included. The use of Auger neutralization as a tool in studying solid surfaces is considered. (A.G.W.)

58693 SPUTTERING. Thompson, M. W. (Univ. of Sussex, Brighton, Eng.). pp 211-22 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Effects of factors such as ion energy, temperature, and angle of incidence on sputtering yields are reviewed. Methods of measurement of angular and energy distributions of sputtered particles are illustrated briefly, and some typical results are shown. (A.G.W.)

58694 SCATTERING OF HELIUM ATOMS BY PHONONS IN THE (001) SURFACE OF LiF AT 150°K. Williams, Brian R. (National Research Council of Canada, Ottawa). J. Chem. Phys.; 55: No. 7, 3220-35(1 Oct 1971).

Results are presented for the scattering of a beam of helium atoms (obtained from a nozzle source) from a cleaved lithium fluoride surface maintained at 150°K. The scattering patterns reveal two types of scattering events: (1) coherent scattering, showing a large number of diffraction peaks not reported to date,

XUM

and (2) inelastic scattering resulting from the vibrations of surface atoms. This component of scattering is observed in the neighborhood of the elastic peaks, in the form of streaks extending in particular directions outward from the Bragg angle. The shapes of the scattering patterns obtained follow the general predictions made for bounds imposed on the scattering surface by the incident velocity of the helium atom. (auth)

58695 ELECTRON LOSS AND CAPTURE CROSS SECTIONS FOR MULTIPLY CHARGED IONS IN SOLID MATTER. Teplova, Ya. A.; Dmitriev, I. S.; Nikolaev, V. S. (Moscow State Univ.). J. Phys., B (London): 4: No. 9, L70-2(Sep 1971).

The dependence of the equilibrium charge distribution of light ions with atomic numbers Z from 4 to 8 on the film thickness was investigated for ions moving at velocities $v \simeq (8 \text{ to } 11) \times 10^8$ cm sec^{-1} in thin celluloid films. It was found that, at $U < V_0 Z$, equilibrium thickness is a function of the initial ionic charge and the electron-capture cross section for charged ions in solids is less than that in gases. (auth) (UK)

58696 THEORY OF THE QUADRATIC ZEEMAN EFFECT. Edmonds, A. R. (Imperial Coll. of Science and Tech., London). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.71-4(Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The existence of previously unobserved structures in the spectra of atoms in magnetic fields was established from high-resolution work carried out at Argonne. These structures may be attributed to a second degree term of the Hamiltonian in the magnetic field, which gives rise to a formally nonseparable problem. The relevant parameters are such as to render conventional approximations invalid. An attempt is made to overcome these difficulties. Preliminary results show promising agreement with the data. (auth) (France)

58697 4f–5d INTERACTIONS IN SAMARIUM, GADOLINIUM, AND TERBIUM. Spector, N. (Israel Atomic Energy Commission, Yavne). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.173-88(Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The newly established levels of the subconfigurations $4\ f^6(^7F)5\ d$ of singly ionized samarium (Sm II), $4f^8(^7F)\ 5d$ of singly ionized gadolinium (Gd II), and $4f^8(^7F)\ 5d\ 6s^2$ of neutral terbium (Tb I) are used to obtain reliable values for the six electrostatic (Slater), and two spin-orbit interaction parameters around the half filled 4f shell. Out of 57 possible levels in each case, 54 of sm^+, 45 of Gd^+, and 27 of Tb are fitted with an rms error of 168 cm^{-1} (1.24% of total width), 239 cm^{-1} (1.76%), and 152 cm^{-1} (1.76%), respectively. L–S coupling notations can be used for level designations despite some heavy admixtures. Eigenvectors differing significantly from previously published valves as well as predictions for missing levels are tabulated. About 70 Gd II lines are classified. (auth) (France)

58698 ACCURATE ANALYTICAL SELF-CONSISTENT-FIELD WAVE FUNCTIONS FOR Dy^{2+}. Synek, M.; Ramirez, R. (Texas Christian Univ., Fort Worth). J. Chem. Phys.; 55: No. 4, 1946-8(15 Aug 1971).

Accurate analytical self-consistent-field (SCF) wave functions were calculated for the dysprosium laser-active ion, namely for Dy^{2+} (Z = 66), $4f^{10}$, ^5I. These ab initio calculations were done by the analytical SCF expansion method, with full exchange effects for all the 64 electrons included. All of the basis function exponents in the analytical expansions were exhaustively optimized. These results represent the only analytical wave functions for Dy^{2+} available at this time. The usual accuracy criteria were satisfied in these calculations. (auth)

58699 ELECTRONIC TRANSITION MOMENT OF THE LYMAN BANDS OF H_2 ($B^1\Sigma_u^+ - X^1\Sigma_g^+$ AS A FUNCTION OF INTERNUCLEAR SEPARATION. Marchetti, M. A.; La Paglia, S. R. (Georgetown Univ., Washington, D. C.). J. Chem. Phys.; 55: No. 4, 1655-61 (15 Aug 1971).

The LCAO–MO–CI method is applied to the study of the electronic transition moment of the Lyman bands of H_2 ($B^1\Sigma_u^+ - X^1\Sigma_g^+$) over the range of internuclear separations $1 \leq R \leq 6$ a.u. It is found that configuration interaction is responsible for a strong nonlinear variation of the transition moment with internuclear distance (maximum transition moment at 3.0 a.u.). Comparison with other calculations indicates that the method is applicable to more complicated molecules and permits the examination of how individual electron correlation effects contribute to the transition moment. (auth)

58700 LABORATORY DETERMINATION OF THE FREQUENCY OF THE 10 CENTIMETER RADIO LINE OF CH BY OPTICAL MEASUREMENTS. Baird, K. M.; Bredohl, H. (National Research Council, Ottawa). Astrophys. J.; 169: No. 2, L83-6(15 Oct 1971).

A new method of photographic Fabry–Perot interferometry was used to measure the Λ doubling of the $J = \frac{1}{2}$ level in the electronic ground state of CH. The value of 3374 ± 15 MHz agrees with Douglas and Elliott's extrapolated value but not with Miller Goss's direct measurements. (auth)

58701 ANALYSIS OF THE ARC AND SPARK SPECTRUM OF SCANDIUM. Neufeld, Lorin Wesley. Manhattan, Kan.; Kansas State Univ. (1970). 139p. University Microfilms Order No. 71-17,365.

Thesis.

Reanalysis and extension were made of the arc and spark spectra of scandium. Observations were made with a 3.4-meter Ebert-type spectrograph. It has a dispersion approximately twice that obtained in previous work on scandium. A total of nearly 1,600 lines are reported, about twice the number previously reported. They were measured with a probable error of from 3mÅ in the ultraviolet to 10mÅ in the near infrared. Using previously published energy level values, finding lists were constructed for ScI and ScII. All lines fitting into one of these level systems were then identified. The remaining unclassified lines were then used in a computer search for new levels. A total of 22 new high even and 2 high odd levels are added to the ScI level system. No new levels are added to the Sc II level system. A total of 138 lines are classified in the Sc II level system and 634 lines are classified in the Sc I level system. The classified lines were then used to determine new values for the energy levels. Exposures were obtained with the scandium electrodeless discharge lamp in a magnetic field. From these exposures, the Zeeman effect was observed and measured. The g-values for 18 Sc II levels and for 71 Sc I levels are reported. A total of 14 published Sc I levels are determined to be false and are removed from the energy level list. A comparison is made with the recent theoretical calculations of level values and g-values for both Sc I and Sc II. (Diss. Abstr. Int., B)

58702 EXCHANGE PERTURBATION THEORY AND THE HeH^+ ION. Certain, Philip R. (Univ. of Wisconsin, Madison). J. Chem. Phys.; 55: No. 6, 3045-6(15 Sep 1971).

It is demonstrated that when exchange perturbation theory is applied to the first two excited states of the molecular ion HeH^+ the first-order theory does not give even the correct sign of the exchange energy for the two states. It is pointed out that in this case the zero-order wave function is not necessarily orthogonal to lower zero-order wave functions and that the first-order energy may predict too large a binding energy (or too small a repulsion) for the excited state. The energy may be corrected by going to higher order, but this introduces the mathematical problems of overcompleteness when both covalent and ionic terms are included. (A.G.W.)

58703 SYMMETRY OF EXCITED ELECTRONIC STATES IN URANYL NITRATE CRYSTALS. Komyak, A. I. (Belorussian State Univ., Minsk). Vestsi Akad. Navuk BSSR, Ser. Fiz.-Mat. Navuk; No. 2, 85-8(1969). (In Russian).

On the basis of the absorption spectra of uranyl nitrate crystals at room and low (77°K) temperatures, the symmetry of four electronic excited states of the uranyl ion is discussed. In uniaxial crystals ($RbUO_2(NO_3)_3$, $CsUO_2(NO_3)_3$, and $NH_4UO_2(NO_3)_3$) the designation of types of symmetry was carried out in agreement with the point group D_{3h}, and in biaxial crystals with D_{2h}. According to neutron-diffraction data, higher symmetry (D_{6h}) is not realized in uranyl nitrate crystals. Comparison with types of symmetry reported in the literature was carried out. (tr-auth)

58704 GREEN'S FUNCTION FOR THE HYDROGEN MOLECULAR ION H_2^+. Laurenzi, Bernard J. (State Univ. of New York, Albany). J. Chem. Phys.; 55: No. 6, 2681-4(15 Sep 1971).

The exact Green's function for the one-electron two-center molecule H_2^+ was found. It is a remarkably mild generalization of the well-known Green's function for the atom He^+. (auth)

58705 PRESENT STATE OF THE ANALYSIS OF Nd I AND Nd II. Blaise, J. (CNRS, Orsay, France); Wyart, J. F.; Hoekstra, R.; Kruiver, P. J. G. J. Opt. Soc. Amer.; 61: No. 10, 1335-42(Oct 1971).

XU

Nd I and Nd II spectra emitted by an electrodeless tube were observed between 2450 and 40,500 Å. By means of 25,000 wavelengths measured with an automatic comparator and of the Zeeman patterns of the strongest lines, about 1500 energy levels were found. Their interpretation was carried out with the use of isotopic-shift data and empirical parametric calculations. The present state of the classification is described. The main features of the 15 known configurations and some results of theoretical calculations are given. (auth)

58706 CONFIGURATIONS $4f^{N-1}6s^2 6p$ IN NEUTRAL GADOLINIUM, DYSPROSIUM, ERBIUM, AND YTTERBIUM. Spector, Nissan (Israel Atomic Energy Commission, Yavne). J. Opt. Soc. Amer.; 61: No. 10, 1350-4(Oct 1971).

The groups of six levels obtained by adding, in J−j coupling, a 6p electron to the lowest level of the $4f^{N-1}$ core were identified in gadolinium, dysprosium, erbium, and ytterbium (N = 8, 9, 12, 14). They account for strong transitions to the corresponding $4f^{N-1}5s6s^2$ configurations. Values for the spin−orbit parameter of the 6p electron are (in cm^{-1}) $\zeta_p = 1835, 1840, 2049, 2257$, respectively. (auth)

58707 RESONANCE LINES OF La III. Johansson, Sveneric; Litzen, Ulf (Univ. of Lund, Sweden). J. Opt. Soc. Amer.; 61: No. 10, 1427-8(Oct 1971).

The 5d−4f lines of La III were recorded, and the wave numbers obtained were used for calculating energy levels. The accuracy of the new energy levels is estimated to be better than 0.02 cm^{-1}. (A.G.W.)

58708 SPECTRA OF NEUTRAL AND SINGLY IONIZED HOLMIUM. Livingston, A. E. Jr.; Pinnington, E. H. (Univ. of Alberta, Edmonton). J. Opt. Soc. Amer.; 61: No. 10, 1429-30 (Oct 1971).

The techniques of Zeeman-effect analysis, hyperfine-structure measurement, and computer searching for repeating energy differences were applied to the spectra of Ho I and Ho II. The eight patterns in the Zeeman-effect spectrum of Ho I that were resolved and sufficiently complete to yield g values are tabulated. No resolved Zeeman patterns for Ho II were found. A computer search based on the 547 Ho II lines contained in the NBS list yielded 10 pairs of lines having wave-number differences near 637.8 cm^{-1} and hfs-width differences near 3.1 cm^{-1}. On the basis of these results, 10 excited-state levels are proposed. (A.G.W.)

58709 THEORETICAL CALCULATION OF ENERGY LEVELS FOR RARE EARTH ELEMENT IONS. Shadzhyuvene, S. D.; Surgailene, R. T.; Ripskite, P. V.; Bogdanovichyus, P. O.; Karaziya, R. I. (Inst. of Physics and Mathematics, Vilnyus, USSR). Liet. Fiz. Rinkinys; 10: No. 6, 873-86(1970). (In Russian).

Using radial integrals calculated by the Hartree−Fock method, the energy levels for Ce III, Pr III, Pr IV, and Nd IV involving one open $4f^N$(N = 2, 3) shell are theoretically determined. The energy spectra obtained are discussed and compared with experimental and semi-empirical results. A program for the BESM-4 computer allowing one to calculate the energies of free atoms and ions, containing one or two open shells, is described. (auth)

58710 ATOMIC WAVE FUNCTIONS USEFUL FOR MOLECULAR CALCULATIONS: SOME STATES OF THE He ATOM. Gupta, B. K. (Osmania Univ., Hyderabad, India). Indian J. Pure Appl. Phys.; 9: No. 4, 261-2(Apr 1971).

Atomic wave functions for the ground 1^1S and excited 2^3S, 2^1P, and 2^3P states of the He atom are reported. The wave functions, obtained using a limited number of configurations, are constructed by forming bond functions from Slater determinants and projecting them for the appropriate state, using configuration interaction. Full optimization of the nonlinear parameters was carried out. The wave functions described are particularly suited for use in calculations for molecules in which the He atom, in one or more of the above states, forms a constituent part. The energies calculated using these wave functions compare well with those obtained from earlier calculations. (auth)

58711 $\sigma-\pi$ SEPARATION: EXCITED H_2 AS A MODEL SYSTEM. Zemke, Warren T. (Illinois Inst. of Tech., Chicago). Theor. Chim. Acta; 22: No. 1, 23-38(1971).

The low-lying Π states of H_2 consist of one core (σ) and one valence (π) electron and afford a direct evaluation of intershell $\sigma-\pi$ interaction. After resolution of the electronic energy into σ only, π only, and $\sigma-\pi$ parts, it is shown that an electronic change in this model system is due solely to a change in the π electrons. Simple Hückel theory is examined. If the molecular core is represented properly, regardless of the π wave function the calculated α and β parameters are in reasonable agreement with the "empirical" parameters. This agreement appears to be due to a fortuitous cancellation of energy contributions. (auth)

58712 FIRST ORDER DENSITY MATRICES FROM CONFIGURATION INTERACTION WAVEFUNCTIONS FOR H_3^+. Duben, Anthony Joseph. University Park, Pa.; Pennsylvania State Univ. (1970). 138p. University Microfilms Order No. 71-16,594. Thesis.

Four configuration-interaction calculations were performed on the $D_{3h}H_3^+$ ion using a Gaussian lobe basis. Both single and double excitations were considered. The best calculation has an energy of −1.34050 hartrees at an internuclear distance of 1.6405 bohrs. Various one-electron molecular properties and plots of the electron density were determined for each wave function. Analyses of the wave functions by both the density-matrix−natural-orbital and the Sinanoglu theories show that single excitations are not negligible with respect to the double excitations in determining the electron density and in the calculation of one-electron properties. In addition, the corrections to the electron density due to the single excitations and due to the double excitations are essentially separable effects. The double excitations tend to shift electron density out away from the molecule. The single excitations tend to return electron density to the region of the molecular framework, especially in the vicinity of the nuclei themselves. (Diss. Abstr. Int., B)

58713 HULTHEN TRANSFORM FUNCTIONS FOR THE EXCITED STATES OF TWO-ELECTRON ATOMS. Gruninger, John (West Virginia Univ., Morgantown). J. Chem. Phys.; 55: No. 7, 3561-3(1 Oct 1971).

Hulthén functions are used to approximate the 2p and 3d orbitals of the lowest ^1P, ^3P, ^1D, and ^3D states of helium and to approximate the 2p orbitals of the lowest ^3P states of the two-electron ions of Li, Be, and B. The orbital approximations and energies of the singlet states obtained using Hulthén 1p and 2d functions are identical to those obtained by Chong from minimal basis Slater 2p and 3d functions. The Hulthén 1p functions differ significantly from the Slater 2p functions only for the ^3P states. The energies obtained for the ^3P states are lower than those obtained from the minimal basis Slater functions. Using the new results for the ^1P and ^3P states of He, a term separation of 0.0087 a.u. is obtained. This value is in close agreement with the Hartree−Fock value of 0.0088 a.u. (auth)

58714 ELECTRONIC RECOMBINATION COEFFICIENT OF MOLECULAR HELIUM IONS. Johnson, A. Wayne; Gerardo, J. B. (Sandia Labs., Albuquerque, N. Mex.). Phys. Rev. Lett.; 27: No. 13, 835-8(27 Sep 1971).

The effect of metastable−metastable ionizing collisions has been neglected in previous measurements of the electronic recombination coefficient of molecular helium ions. In this study, a source of free electrons was taken into account and the recombination coefficient was observed to be much larger than previously reported. Over the pressure range from 15 to 50 torr, this coefficient was measured to range from $(1.8 \text{ to } 4.3) \times 10^{-8}$ cm^3 sec^{-1}. (auth)

58715 IONIZATION POTENTIALS OF ATOMS AND IONS CONTAINING ONE TO TEN ELECTRONS. Edlen, Bengt (Lund Univ., Sweden). pp 133-45 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

With increasing degree of ionization, accurate ionization potentials can be obtained by direct observations for only a limited number of spectra in the beginning of each isoelectronic sequence; for the rest, extrapolations must be used. Since the author discussed this problem at length earlier (J. Chem. Phys., 33: 98 (1960)) a wealth of new experimental data has become available, and much progress has been made from the theoretical side. Therefore, the subject is reviewed here after collecting experimental and theoretical results for confrontation and synthesis. The discussion is limited to the first ten electronic systems, the only ones for which reasonably definite results can be given at the present time. 30 references. (L.M.T.)

58716 Z DEPENDENCE OF SPIN−ORBIT COUPLING. Fano, U. (Univ. of Chicago); Martin, W. C. pp 147-52 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

The systematic variation of the spin−orbit coupling strength along the periodic system is discussed. The main point is displayed in a plot of suitably reduced values of the p-electron coupling strength. The data are experimental values for configurations of the type (core)np in neutral atoms. These values are clustered along a straight line in a log−log plot against the atomic number Z. The line's slope is ~2.33. (auth)

XUM

58717 BEUTLER–FANO SHAPE IN THE PREDISSOCIATION OF H_2. Herzberg, G. (National Research Council of Canada, Ottawa). pp 191-7 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

From recent studies of the far-ultraviolet absorption spectra of H_2 and D_2 the author reports some striking examples of Beutler–Fano shapes in predissociation, a phenomenon not observed before. (L.M.T.)

58718 TRANSITION PROBABILITIES AND FRACTIONAL OCCUPATION NUMBERS IN ATOMS. Slater, J. C. (Univ. of Florida, Gainesville). pp 297-303 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

The author and collaborators have earlier pointed out the usefulness of a statistical exchange for calculations of self-consistent fields in crystals, and incidentally in atoms. One of the characteristics of the use of the statistical exchange is that the eigenvalues, representing one-electron energies, do not agree well with the Hartree–Fock values or with experimental excitation and ionization energies; the explanation of this has been pointed out in terms of the use of fractional occupation numbers of electrons in the various orbitals. It is now possible to tie together some of the properties of the statistical exchange and the fractional occupation numbers more effectively than was done heretofore, as the author and Wood (Int. J. Quant. Chem., 4S: 3(1971)) have shown. In this note the interesting application of the ideas developed earlier to the calculation of transition probabilities in atoms is pointed out. (auth)

58719 FLUORESCENCE, AUGER, AND COSTER–KRONIG L_{II} SUBSHELL YIELDS OF THORIUM. Ferreira, J. G.; Soares, J. C.; Barroso, A.; Gil, F. B. (Univ. of Lisbon). J. Phys., A (London); No. 5, 679-84(Sep 1971).

Fluorescence (ω_2), Auger (a_2), and Coster–Kronig (f_{23}) L_{II} subshell yields in thorium were determined from measurement of L x rays emitted following α decay of ^{232}U. α–x coincidence techniques, employing a surface barrier detector for the α particles and a NaI(Tl) scintillation counter for L x rays, were used to measure the total fluorescence yield $\overline{\omega}_L$ of the L shell in ^{228}Th. The relative intensity of the L x photons from the L_{II} and the L_{III} subshells was determined with a Si(Li) L x ray spectrometer. The experimental results are: $\omega_2 = 0.44 \pm 0.03$; $f_{23} = 0.13 \pm 0.10$; $a_2 = 0.43 \pm 0.10$, and $\overline{\omega}_L = 0.46 \pm 0.03$. (auth) (UK)

58720 MEASUREMENT OF THE 2^3P_0-2^3P_1 FINE STRUCTURE INTERVAL OF ^4He. Kponou, Ahovi E. F. New Haven; Yale Univ. (1970). 144p. University Microfilms Order No. 71-16,503.

Thesis.

The $2^3P_0-2^3P_1$ fine-structure interval of the helium atom (He^4) was measured by the optical–microwave atomic-beam magnetic resonance method. The transition $(J,m_J) = (0,0) \rightarrow (1,0)$ was observed at a magnetic field of about 320 G. Seventy-three resonances were observed. The result is $\nu_{01} = E(2^3P_0) - E(2^3P_1) = 29\,616.862 \pm 0.033$ MHz (1.11 ppM), in which the error represents one standard deviation and is due mainly to counting statistics. This result is to be compared with $\nu_{01} = 29\,616.76 \pm 0.40$ MHz obtained by a level-crossing experiment. The present experimental accuracy (≈1 ppM) makes it possible to eventually determine the value of the fine-structure constant α to better than 1 ppM provided the theoretical expression for ν_{01}, in which α is treated as unknown, can be determined to an accuracy of at least 2 ppM. An alternative interpretation of the result is to use an independent determination of the fine-structure constant to compare measurements of ν_{12} and ν_{01} with their calculated values as a check of the theory. (Diss. Abstr. Int., B)

58721 DENSITY OF STATES IN THE STATIC SCREENED COULOMB POTENTIAL. Preist, T. W. (Univ. of Exeter, Eng.). J. Phys., B (London): 4: No. 9, 1129-39(Sep 1971).

Regge trajectories are calculated for the screened Coulomb potential with screening radii in the range 10^{-6} to 10^{-3} cm corresponding to an ionized hydrogen gas of temperature 5000°K and electron density 10^{11} to 10^{17} cm^{-3}. The Regge trajectories are used to compute the density of states as a function of energy and the results suggest a simple parametric form for this function. The calculation also yields information on the upper bound to the principal quantum number and the start of the quasi-continuum. (auth) (UK)

58722 LIFETIMES AND RELATIVE INITIAL-STATE POPULATIONS OF SOME HYDROGEN ATOMIC STATES USING BEAM-FOIL SPECTROSCOPY. Schuermann, D.; Schlagheck, W.; Heckmann, P. H.: Bukow, H. H.; Buttlar, H. v. (Ruhr-Univ., Bochum, Ger.). Z. Phys.; 246: No. 3, 239-47(1971). (In German).

H_2^+ ions or protons, accelerated to energies between 80 and 300 keV, are sent through a thin carbon target. Light emitted by the excited atoms moving out of the foil with a definite velocity is analyzed using interference filters and a cooled photomultiplier. Intensities of the H_α, H_β, and H_γ lines are measured as functions of the distance from the foil. The data are analyzed with a computer program, which yields (in agreement with theory) mean lives of the hydrogen-atom excited states involved and the relative initial-state populations of states belonging to the same principal quantum number. There is no indication of cascading. (auth)

Positronium, Muonium, and Mesic Atoms and Molecules

58723 CROSS SECTIONS FOR SINGLE-QUANTUM ANNIHILATION OF LOW-ENERGY POSITRONS IN IODINE. Friedrich, Hans (Univ., Goettingen, Ger.). Z. Phys.; 246: No. 5, 407-17 (1971). (In German).

Positrons of 200 keV were focused on a slice of NaI. This acted as a scintillation spectrometer and measured the energy loss of the positrons before annihilation. Single quanta, produced with a probability of only 2.6×10^{-5}, were registered by a second NaI detector. Two-parameter analysis of the coincidences between these two detectors allowed the determination of six cross sections for single-quantum annihilation between positron energies of 80 and 180 keV. The cross section at 180 keV was 0.09 barn per iodine atom and decreased with decreasing positron energy due to the Coulombic repulsion. Quantitative agreement was obtained with theoretical calculations within the limits of error. (auth)

58724 CASCADE PROCESS IN MESIC ATOMS. Atarashi, Masaru; Narumi, Hajime (Hiroshima Univ.). Progr. Theor. Phys. (Kyoto); 45: No. 6, 1779-85(Jun 1971).

In response to the recent precise measurement of mesic x-ray yields, it became possible to discuss the cascade process in mesic atom more exactly. It is shown for the muonic atom of ^{12}C that the statistical distribution of the initial mesic bound states is more reasonable than the modified one earlier obtained by Eisenberg and Kessler. On the basis of this consideration, mesic cascade processes, including strong absorption as well as natural decay, are fully analyzed and typical calculations are carried out for pionic ^9Be, ^{12}C, and ^{16}O. The results are in good agreement with recent experimental ones. (auth)

58725 POSITRON PROCESSES IN HYDROGEN, HELIUM, ARGON, AND NEON GAS. Canter, Karl Frederick. Detroit, Wayne State Univ. (1970). 104p. University Microfilms Order No. 71-17,242.

Thesis.

The time dependence of positron annihilation in hydrogen, helium, argon, and neon gas was measured at various densities and temperatures. The lifetime spectra were obtained with conventional coincidence circuitry. A variable-temperature cryostat was employed to obtain data from 4.6 to 300°K. It is found that the lifetimes of ortho-positronium in helium gas are in good agreement with those predicted by the cavity model, when a scattering length of 0.77 ± 0.04 Å is used. It is also found that the cavity model, as presented, loses its validity for small cavity radii (less than 9 Å). The lifetime spectra of positrons that do not form positronium (low-energy positrons) are observed to exhibit unusual behavior with respect to changes in density and temperature for helium and argon gas. This behavior is interpreted as resulting from the low-energy positrons being trapped in the gas after slowing down, via elastic collisions with the gas atoms, to an energy, E_r. The trapping of the positron allows a high-density electrostricted cluster of atoms to form about the positron; this results in a much larger decay rate of the positron than that observed at high temperatures for unlocalized positrons. The following estimates of E_r are deduced from the data: for helium, $E_r = 1.3 \times 10^{-3}$ to 10^{-2} eV; for argon, $E_r = 0.5$ to 2.6 eV. No evidence for the trapping of low-energy positrons in neon gas could be found. (Diss. Abstr. Int., B)

Collision Phenomena

58726 ABSOLUTE CROSS SECTION FOR ELECTRON IMPACT EXCITATION OF 3914-A N_2^+. McConkey, J. W. (Univ.

of Windsor, Ont.); Woolsey, J. M.; Burns, D. J. Planet. Space Sci.; 19: No. 9, 1192(Sep 1971).

In a recent paper Borst and Zipf (1970) have pointed out that the excitation function reported by McConkey et al. (NSA 22: 17423) displayed anomalous threshold behavior in that the cross section displayed in a figure of that paper appeared to have a nonzero value at threshold. This was due to a drawing error. In view of the interest in this cross section it was felt worthwhile to present the low-energy data of McConkey et al. in some detail. These data are presented in tabular form and were corrected for the overlapping second positive and first negative bands. The energy scale was adjusted so that the appearance potential of the band is the spectroscopic value. (auth)

58727 COLLINEAR COLLISIONS OF AN ATOM AND A MORSE OSCILLATOR: AN APPROXIMATE SEMICLASSICAL APPROACH. **Morse, Robert I.; LaBrecque, Rodney J. (Clark Univ., Worcester, Mass.). J. Chem. Phys.; 55: No. 4, 1522-30 (15 Aug 1971).**

The semiclassical treatment by Heidrich, Wilson, and Rapp of atom–harmonic–oscillator collinear collisions with exponential and Morse repulsive potentials is extended to include collisions, with the same potentials, between an atom and a Morse oscillator. The classical equations of motion for the Morse oscillator system lead to a differential equation that can be solved in the same form as the harmonic oscillator system by an iterative method. It is found that for vibrational transitions between low-lying levels and for relative translational energies on the order of several oscillator quanta only one or two iterations are necessary for convergence to within a few percent. The results are compared with a calculation for harmonic oscillator systems. (auth)

58728 DISSOCIATIVE EXCITATION OF VACUUM ULTRAVIOLET EMISSION FEATURES BY ELECTRON IMPACT ON MOLECULAR GASES. I. H_2 AND O_2. **Mumma, M. J.; Zipf, E. C. (Univ. of Pittsburgh). J. Chem. Phys.; 55: No. 4, 1661-9(15 Aug 1971).**

The H I ($2p^1\ {}^2P \rightarrow 1s^1\ {}^2S$) 1215.67-Å Lyman-alpha line and the O I ($3s^1\ {}^3S^0 \rightarrow 2p^4\ {}^3P$) 1302.17-, 1304.87-, 1306.04-Å multiplet were excited by electrons impacting on H_2 and O_2, respectively. Their excitation cross sections were measured over the energy range from threshold to 350 eV. The cross section for dissociative excitation of Lyman-alpha has a peak value of 1.23×10^{-17} $cm^2 \pm 11\%$, and the cross section for the O I 1300-Å multiplet has a maximum value of 3.8×10^{-18} $cm^2 \pm 17\%$. The cross section for dissociative excitation of the O I ($3s^1\ {}^1P^0 \rightarrow 2p^4\ {}^1S$) 1217.6-Å line is 1.5×10^{-19} $cm^2 \pm 24\%$ at 100 eV. (auth)

58729 LYMAN-ALPHA EMISSION INDUCED BY THE COLLISIONS OF ELECTRONS WITH MOLECULAR HYDROGEN. **Kauppila, W. E.; Teubner, P. J. O.; Fite, W. L.; Girnius, R. J. (Univ. of Pittsburgh). J. Chem. Phys.; 55: No. 4, 1670-2(15 Aug 1971).**

The ratio of electron-impact cross sections of atomic and molecular hydrogen for production of uv radiation detected by an oxygen-filtered iodine-vapor-filled photon counter was precisely measured in a modulated-beam experiment. Using a filter 1.67 cm long with an oxygen pressure of 1 atm, the ratio of cross sections at 100 eV was found to be 4.05 ± 0.07. Using the known cross section for production of Lyman-alpha radiation from the hydrogen atom, the cross section for molecular radiation received by the detector was determined to be $1.48\ (\pm 0.05) \times 10^{-17}$ cm^2. (auth)

58730 SPURIOUS DISSOCIATIVE ATTACHMENT PEAKS FROM INELASTIC LOSS REACTIONS. **Chantry, P. J. (Westinghouse Research Labs., Pittsburgh). J. Chem. Phys.; 55: No. 4, 1851-60(15 Aug 1971).**

Peaks in the electron energy dependence of negative-ion production are usually the direct result of dissociative attachment reactions of the type $e + XY \rightarrow XY^{*-} \rightarrow X^- + Y$. Each such peak is related to a particular intermediate molecular negative ion state XY^{*-} and provides an approximate estimate of the energy of that state in the Frank–Condon region. A dissociative attachment peak may, however, be accompanied by a smaller "partner" peak at a higher electron energy at which an inelastic energy-loss collision leaves the electron with an energy at which subsequent dissociative attachment can occur. Thus the separation of the partner peak from the main dissociative attachment peak equals the most probable energy loss. A peak in the production of O^- from O_2 at 15 eV, observed previously but not satisfactorily explained, was studied experimentally and is shown to arise from the above-described reaction sequence involving the loss of ~8.4-eV energy by excitation of the B ${}^3\Sigma_u^-$ dissociation continuum. Satisfactory correlation of the observations with published energy-loss spectra is demonstrated, and the expected quadratic pressure dependence of the signal is confirmed. In addition a technique is described whereby the energy of the electrons directly responsible for the ion production is measured even though it differs from that of the primary electron beam. On the basis of the present observations it is concluded that in the region of 15 eV essentially all of the energy loss occurs through the 8.4-eV process, and the inelastic cross sections of Hake and Phelps are appropriately reapportioned. Peaks in the production of O^- from N_2O in the region 7- to 15-eV beam energy are shown to have a quadratic pressure dependence and are ascribed to the same general mechanism. Correlations with known energy losses are, however, less satisfactory than in the O_2 case. Possible reasons for this are suggested. Peaks in O^- production from CO at 16 and 18.3 eV arise from excitation of the A ${}^3\pi$ and A ${}^1\pi$ states. The relative magnitudes of these two excitation cross sections apparently change dramatically with increasing electron energy. Two peaks in O^- production from NO, at 14.2 and 15 eV, are similarly correlated with known energy losses and the first of these peaks is ascribed to excitation of the $c^2\pi$ and/or the $D^2\Sigma^+$ state. (auth)

58731 TEMPERATURE DEPENDENCE FOR THE DESTRUCTION OF METASTABLE He(2^3S) ATOMS. **LoDato, Vincent A.; Katsuura, Kanji (Univ. of Notre Dame, Ind.). J. Chem. Phys.; 55: No. 4, 1999(15 Aug 1971).**

Total cross sections for the reaction $He(2^3S) + He(2^3S) \rightarrow He(1S) + He^+ + e$ are reported as a function of temperature from 5 to 300°K. It is found that the total cross section increases as the temperature decreases and that there is a relatively small change (8.5×10^{-16} cm^2) between 77 and 300°K. (A.G.W.)

58732 SELECTION RULE FOR $\Sigma^+ \rightleftharpoons \Sigma^-$ TRANSITIONS IN ELECTRON–MOLECULE COLLISIONS. Cartwright, D. C. (Aerospace Corp., Los Angeles); Trajmar, S.; Williams, W.; Huestis, D. L. Phys. Rev. Lett.; 27: No. 11, 704-7(13 Sep 1971).

The differential cross section for the electron-impact excitation of the b ${}^1\Sigma_g^+$ state from the ground state of O_2 is found to decrease rapidly as the scattering angle approaches zero. This behavior is the diatomic-molecule analog of "parity-unfavored" transitions in electron–atom scattering. A group-theoretic argument is given, which explains the observations and provides a selection rule for $\Sigma^+ \rightleftharpoons \Sigma^-$ transitions in diatomic molecules. (auth)

58733 INTERPRETATION OF THE ENERGY SPECTRUM OF ELECTRONS PRODUCED IN ATOMIC COLLISIONS. **Gordeev, Yu. S.; Ogurtsov, G. N. (Ioffe Inst. of Physics and Tech., Leningrad). Zh. Eksp. Teor. Fiz.; 60: No. 6, 2051-9(Jun 1971). (In Russian).**

The effect of atomic-collision kinematics on the character of the emitted electron spectrum is studied. It is shown that Doppler line shift and broadening in the spectrum of electrons produced in inelastic processes involving considerable scattering of the atomic particles noticeably distort the shape of the spectrum. The position and width of the spectral lines depend not only on the energy and lifetime of the autoionization levels but also on the energy and scattering angle distribution of the colliding particles. The energy spectrum of electrons related to excitation of autoionization states of argon and helium in Ar^+–Ar and He^+–He collisions is calculated. The results of the calculation are qualitatively in good agreement with the available experimental data. (auth)

58734 ORBITAL QUANTUM NUMBER DISTRIBUTION OF HIGHLY EXCITED ATOMS PRODUCED IN COLLISIONS BETWEEN HEAVY PARTICLES. **Vinogradov, A. V.; Urnov, A. M.; Shevel'ko, V. P. (Lebedev Inst. of Physics, Moscow). Zh. Eksp. Teor. Fiz.; 60: No. 6, 2060-5(Jun 1971). (In Russian).**

Collisions between fast protons or atoms and various atomic targets involving formation of highly excited hydrogen atoms H(nl), $n \gg 1$, are considered. The dependence of the charge-exchange and excitation cross sections on orbital momentum l is derived. As expected, hydrogen atoms are produced with greatest probability in states with l = 0, 1. Numerical calculations carried out for collisions with argon atoms show that the formulas derived in the present paper are valid for principal quantum number values as low as $n \gtrsim 3$. (auth)

58735 STUDY OF COLLISIONS BETWEEN LOW-ENERGY N^+ AND N_2: REACTION CROSS SECTIONS, ISOTOPIC COMPOSITIONS, AND KINETIC ENERGIES OF THE PRODUCTS. **Maier II, William B. (Los Alamos Scientific Lab., N. Mex.); Murad, Edmond. J. Chem. Phys.; 55: No. 5, 2307-16(1 Sep 1971).**

Reactive collisions between N^+ and N_2 were studied, and cross sections for the production of N_2^+ were measured for initial kinetic energies, $E_{c.m.}$, in the center-of-mass system between 1 and 70

XUM

eV. The kinetic energies of the product N_2^+ were determined. Isotopically labeled reactants were used, and the cross sections for producing N_2^+ containing different combinations of isotopes were measured. The reaction (1) $N^+ + N_2 \rightarrow N_2^+ + N$ is found to proceed by both atom and electron transfer. For $E_{c.m.} \lesssim 11$ eV, the cross sections for electron and atom transfer are roughly equal, but at higher $E_{c.m.}$ the atom-transfer cross section is considerably smaller than the electron-transfer cross section. The kinetic energy −Q transferred into internal energy of the products is considerably larger than the minimum required for Reaction (1) to proceed. For the electron-transfer process, the values determined for −Q are between 3 and 9.8 eV. The values of −Q found for the processes associated with atom transfer are between 3 and 50 eV. For $E_{c.m.} \gtrsim 24$ eV, it appears that a free electron may be produced by $N^+ + N_2 \rightarrow N_2^+ + N^+ + e$. A model for the reactions occurring in collisions between N^+ and N_2 is developed and shown to be in qualitative agreement with the observations. (auth)

58736 DETERMINATION OF THE K–LL AUGER SPECTRA OF N_2, O_2, CO, NO, H_2O, AND CO_2. Moddeman, W. E. (Oak Ridge National Lab., Tenn.); Carlson, Thomas A.; Krause, Manfred O.; (and others). J. Chem. Phys.; 55: No. 5, 2317-36 (1 Sep 1971).

A double-focusing electrostatic electron spectrometer was used to measure the K–LL Auger spectra resulting from electron impact for each of the elements in the gaseous molecules N_2, O_2, CO, NO, H_2O, and CO_2. An energy resolution of 0.09% full width half-maximum was normally employed. A method for analyzing these complex spectra is described. It involves the identification of normal and satellite lines. The former are defined as arising from single electron ionization from the K shell without additional excitation followed by an Auger process in which one electron fills the vacancy while a second goes into the continuum, and where all the other electrons remain in their same orbitals. Satellite lines result when extra excitation occurs either in the initial formation of the K vacancy or in the subsequent Auger process. To aid in the identification of these satellite lines, auxiliary experiments have been performed such as the study of discrete energy losses in photoionization due to electron shake-up and the comparison of Auger spectra produced by monoenergetic x rays. As a consequence of the analyses of the Auger spectra, information has been obtained on (1) the nature of initial excitation processes such as the transition of a K electron into excited discrete states and monopole excitation and (2) the identification of the energy and nature of the ground and excited states of the doubly charged molecular ions. The second ionization potential was obtained for each of the molecules, and in one case, N_2, the third ionization potential was estimated. Finally, the possible use of high-resolution electron spectroscopy in molecular as well as elemental analysis is discussed briefly. (auth)

58737 SIMPLE ESTIMATE OF TURNING-POINT ERROR IN MATRIX ELEMENTS INVOLVING JWKB WAVE FUNCTIONS. Riley, Merle E. (Sandia Labs., Albuquerque, N. Mex.). J. Chem. Phys.; 55: No. 5, 2606-7(1 Sep 1971).

A simple method for estimating the turning-point contribution to the error in certain JWKB matrix elements is described briefly. The method can be used either as an after-the-fact estimate of the error in a given element or to determine if JWKB functions should be considered. (A.G.W.)

58738 NEW SEMI-EMPIRICAL FORMULA FOR IONIZATION CROSS SECTION OF NEUTRAL ATOMS BY ELECTRON IMPACT. Tripathi, D. N.; Rai, D. K. (Banaras Hindu Univ.). Indian J. Pure Appl. Phys.; 8: No. 12, 843-4(Dec 1970).

A semi-empirical formula was developed for the calculation of cross sections for ionization of neutral atoms by electron impact from the data on incident energy. The formula involves three adjustable parameters, and calculations of ionization cross sections were made for helium and cesium atoms in their ground states. The agreement between the calculated and experimental values is especially good in the case of cesium in the higher incident-energy range and for helium over the entire energy range. (auth)

58739 PHYSICS OF IONIZED GASES. Proceedings of the International Summer School, Hercegnovi, Yugoslavia, July 6–16, 1970. Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970). 733p. (CONF-700706).

Thirty-one lectures were presented in the following fields: atomic collision processes, particle interactions with solids, and phenomena in plasmas. Separate abstracts have been prepared for all the lectures except three, which were previously abstracted as NSA 25: 3061, 3075, and 5094. (D.L.C.)

For abstracts of individual papers see: 58412, 58413, 58691–58693, 58740–58747, 58994–58998, 59005, 59006, 59098–59100, and 59165–59169.

58740 EXCITATION AND IONIZATION OF ATOMS BY ELECTRON AND PROTON IMPACT: APPROXIMATE EXPRESSIONS AND SCALING RELATIONS FOR THE CROSS SECTIONS. Drukarev, G. F. (Leningrad State Univ.). pp 1-25 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Two sources of approximate analytical expressions and scaling relations for ionization and excitation cross sections are considered: (1) the Born approximation and its various modifications and (2) classical calculations of the cross section for energy transfer from the projectile to the target electron. These expressions are used for construction of semi-empirical and interpolation formulas that reproduce the real cross sections within a factor of 1.5 to 2. (A.G.W.)

58741 EXCITATION AND IONIZATION BY ELECTRONS. Zapesochni, I. P. (Uzhgorod State Univ., USSR). pp 26-53 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Experimental methods for study of excitation and ionization by electrons are reviewed briefly. Results of studies of excitation of He, Hg, and the alkali metals and ionization of the alkali metals are summarized. 33 references. (A.G.W.)

58742 ELECTRON CAPTURE AND LOSS PROCESSES FOR HYDROGEN ATOMS, PROTONS, AND NEGATIVE IONS IN ATOMIC AND MOLECULAR GASES: EXPERIMENTAL DATA ON CROSS SECTIONS. Fedorenko, N. V. (Ioffe Inst. of Physics and Tech., Leningrad). pp 54-78 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Experimental data on cross sections for electron-loss processes of hydrogen atoms and negative ions (01, $\bar{1}1$, $\bar{1}0$) in gases and cross sections for electron capture by hydrogen atoms and protons (10, $1\bar{1}$, $0\bar{1}$) are surveyed. The experimental data on cross sections relative to the energy of primary particles are presented in diagrams, separately for all processes mentioned. The summary is given for all the energy ranges used in the cross section measurements published in the open literature, involving energies from a few tens of electron volts up to 20 MeV. The experimental data are considered on the basis of existing predictions for inelastic atomic collisions. The correct interpretation of results obtained by both magnetic mass analysis and condenser methods is discussed. 70 references. (auth)

58743 INVESTIGATION OF THE ELEMENTARY ATOMIC COLLISION PROCESSES WITH CHANGE IN CHARGE STATES BY MEANS OF COINCIDENCE METHOD. Afrosimov, V. V. (Ioffe Inst. of Physics and Tech., Leningrad). pp 79-112 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Investigations of elementary atomic collision processes in which a simultaneous analysis of the charge state of both interacting particles is applied are reviewed. A coincidence method for measuring charge-exchange cross sections is described. To illustrate the use of this method, results are given for collisions of protons and hydrogen atoms with inert gas atoms and hydrogen molecules. (auth)

58744 EXPERIMENTAL POSSIBILITIES OF THE MERGING BEAM TECHNIQUE TO STUDY ION–ATOM COLLISION PROCESSES. Belyaev, V. A. (Inst. of Atomic Energy, Moscow). pp 133-49 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Experimental possibilities of the merging-beams method are discussed in comparison with the conventional methods used for studying ion–atom collision processes. The basic principles of the merging-beams method are presented. (auth)

58745 THRESHOLD LAWS FOR ELECTRON–ATOM COLLISIONS. Grujic, P. (Inst. of Physics, Belgrade). pp 150-74 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Classical and quantum mechanical approaches to the processes of ionization and excitation in electron–atom collisions at near-threshold energies are reviewed. These theoretical results are then compared with various experimental results. 37 references. (A.G.W.)

58746 TRANSITIONS TO THE SUBLEVELS OF THE FINE AND HYPERFINE STRUCTURE IN THE SLOW HEAVY-PARTICLE-ATOMIC COLLISIONS. Chibisov, M. I. (Inst. of Atomic Energy, Moscow). pp 175-80 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

A method is presented for representing slow atomic collision processes in which a change of either the direction or the magnitude of momentum of the atomic electron occurs. Three specific cases are considered: (1) depolarization of a P-state atom (with zero spin) caused by slow collision with a heavy charged particle; (2) resonant depolarization and excitation transfer processes in collisions of two atoms; and (3) relaxation of the 2s hydrogen atom in collision with a proton. (A.G.W.)

58747 SIGNIFICANCE OF THE ENERGY RESOLUTION IN THE EXPERIMENTAL STUDY OF THE ELECTRON–ATOM AND ELECTRON–MOLECULE COLLISIONS. Stamatovic, A. (Inst. of Physics, Belgrade). pp 181-9 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

The importance of energy resolution in experimental studies is illustrated by two examples; results obtained by different investigators under the same conditions except for differences in the width of the electron energy spread are shown for energy losses of 25-keV electrons in argon and for electron attachment to SF_6. Three methods for formation of electron beams with narrow energy spread are reviewed briefly: the 127° sector of a cylindrical electrostatic condenser, the hemispherical electrostatic condenser, and the retarding-potential-difference method. 41 references. (A.G.W.)

58748 NEW VALUES FOR THE PARTIAL-WAVE ELECTRON SCATTERING FACTOR FOR THE ELEMENTS $1 \leq Z \leq 57$ AND $72 \leq Z \leq 90$ FOR INCIDENT ELECTRON ENERGIES OF 10, 40, 70, AND 100 keV. Schafer, L. (Univ. of Arkansas, Fayetteville); Yates, A. C.; Bonham, R. A. J. Chem. Phys.; 55: No. 6, 3055-6 (15 Sep 1971).

Improved numerical techniques for obtaining the partial-wave phase shifts and an improved description of the static potential field for the neutral atoms were used to calculate electron scattering factors. The results are not included here but are presented in document number NAPS-01419, which may be obtained from the Library of Congress. (A.G.W.)

58749 ELECTRONIC EXCITATION IN FAST COLLISIONS OF Na WITH SO_2 AND NO_2. LeBreton, P. R.; Mecklenbrauck, W.; Schultz, A.; Schlier, Ch. (Univ., Freibug i. B.). J. Chem. Phys.; 55: No. 6, 2940-4(15 Sep 1971).

A sputtered Na beam was used to investigate collisionally induced electronic excitation in scattering with SO_2 and NO_2. Light from the radiative decay of excited electronic states was observed at several wavelengths, and measurements were made of the excitation cross sections as a function of the center-of-mass collision energy in the range 1 to 30 eV. In both scattering systems, the most intense light measured originated from the Na ($3^2P \rightarrow 3^2S$) D line. Light from the ($4^2D \rightarrow 3^2P$) Na transition was observed, but its intensity was more than an order of magnitude smaller than that of the D line. Emission also occurred from transitions with long radiative lifetimes (~40 μsec). This emission is probably due to the $B_1 \rightarrow A_1$ molecular transitions of SO_2 and NO_2. The results are discussed in terms of a potential curve-crossing mechanism, which seems to satisfactorily explain collisionally induced alkali-atom excitation. For the molecular emission, an alternate mechanism is considered which involves vibrational coupling of the A_1 and B_1 states. (auth)

58750 IONIZATION OF LONG-LIVED HIGHLY EXCITED ATOMS BY COLLISION WITH MOLECULES. Matsuzawa, Michio (Univ. of Electro-Communications, Tokyo). J. Chem. Phys.; 55: No. 6, 2685-9(15 Sep 1971).

For the ionization of long-lived highly excited atom A^{**} by collision with molecule B, $A^{**} + B \rightarrow A^+ + B + e$, a mechanism is proposed in which an electron in the long-lived highly excited atom is ionized as a result of its energy gain from the molecule by rotational de-excitation. The cross sections at thermal velocities are calculated to be of the order of 10^{-13} cm^2 for polar molecules according to the proposed mechanism. This result is in reasonable agreement with experimental data. (auth)

58751 REACTIONS BETWEEN N_2^+ AND N_2^*. Maier II, William B. (Los Alamos Scientific Lab., N. Mex.). J. Chem. Phys.; 55: No. 6, 2699-2707(15 Sep 1971).

Apparent cross sections for the reactions $N_2^+ + N_2 \rightarrow N^+ + N + N_2$ and $N_2^+ + N_2 \rightarrow N_3^+ + N$ were measured for laboratory kinetic energies E of N_2^+ between 1 and 45 eV. The primary ions are produced by electron bombardment and mass-analyzed prior to reaction. The bombarding electron energy is varied from 19 to 90 eV, and the effects of excited long-lived states of N_2^+ on the reactions are studied. Both reactions proceed when N_2^+ is in long-lived excited states and when N_2^+ is in the $X\,^2\Sigma_g^+$ and/or $A\,^2\Pi_u$ states. When $E \lesssim 15$ eV, Reaction (1) proceeds primarily from long-lived states of N_2^+ about 8.5 ± 1.5 eV above the ground state. There may be several long-lived excited N_2^+ states involved in the production of N^+ and N_3^+ at low E, and some or all of these states may be involved in long-lived emissions previously observed. A survey of the available information on N_2^+ suggests that detailed comparisons with theory will be seriously hampered by uncertainties in the production and lifetimes of the various states of N_2^+. (auth)

58752 DOPPLER BROADENING IN BEAM EXPERIMENTS. Chantry, P. J. (Westinghouse Research Labs., Pittsburgh). J. Chem. Phys.; 55: No. 6, 2746-59(15 Sep 1971).

The distribution in center-of-mass (cm) energy caused by the thermal motion of the target gas molecules has been rigorously derived for the case of a monoenergetic particle beam interacting with target molecules having an isotropic Maxwellian velocity corresponding to temperature T°K. Provided the nominal cm energy E_0 exceeds a few kT, the distribution has a full width at half-maximum (fwhm) of $W_{1/2} = (11.1\gamma kT\,E_0)^{1/2}$, where $\gamma = m/(m + M)$, m and M being the projectile and target masses. This is identical to the width derived previously in a one-dimensional approximate treatment by Bethe and Placzek. The exact and approximate distributions differ significantly, however, in shape and mean energy, particularly at low values of $E_0/\gamma kT$. The Doppler width, $W_{1/2}$, is shown to significantly affect the appearance curve of the products of endothermic reactions involving heavy particles. Convolution integrals are derived for a number of idealized forms of the cross section for such reactions. In the extreme case of a step-function cross section the estimation of the threshold E_T by the usual linear extrapolation technique gives a value that is too low by approximately $0.6W_{1/2}(E_T)$, where $W_{1/2}(E_T)$ is the fwhm evaluated at $E_0 = E_T$. The effect of the thermal velocities of the parent molecules from which the primary beam is formed is considered in the case of an accelerated beam with no kinetic energy imparted to the beam particles by the formation process and in the case where the energy of the interacting particles is controlled only by the kinetic energy released in a resonant dissociative formation process. The latter situation is shown to be described exactly by the equations derived for the monoenergetic beam case provided an appropriately defined equivalent temperature is used in place of the true temperature of the target gas. The results of the present theory are applied to the experimental data of Berkowitz, Chupka, and Gutman on the reactions $I^- + O_2 \rightarrow O_2^- + I$ and $I^- + NO \rightarrow NO^- + I$. In addition data on the reaction $O^- + O_2 \rightarrow O_2^- + O$ are presented and analyzed. The derived thresholds are consistent with $A(O_2) \geq 0.56 \pm 0.10$ eV, $A(NO) \geq 0.06 \pm 0.1$ eV, and $A(O_2) \geq 0.50 \pm 0.1$ eV, respectively. The experimental data of Maier on the reaction $C^+ + D_2 \rightarrow CD^+ + D$ are found to be consistent with a cross section that rises from threshold with approximately twice the slope of the cross section computed by Truhlar from statistical phase space theory. (auth)

58753 ION-IMPACT ENERGY-LOSS SPECTRUM OF OXYGEN. Moore, John H. Jr. (Univ. of Maryland, College Park). J. Chem. Phys.; 55: No. 6, 2760-4(15 Sep 1971).

Electronic transitions in the oxygen molecule arising from ion–molecule collisions were studied by measuring the kinetic energy lost by 100-eV to 4-keV H^+, H_2^+, and He^+ inelastically scattered from O_2. The 7- to 9-eV region of the energy-loss spectrum is strongly collision-energy dependent. The broad feature ordinarily identified as the Schumann–Runge continuum appears to be the result of at least two different transitions. A peak corresponding to the optically forbidden Herzberg continuum ($A\,^3\Sigma_u^+ \leftarrow X\,^3\Sigma_g^-$) is observed in all of the ion-impact spectra. Triplet–singlet transitions into the $a\,^1\Delta_g$ and $b\,^1\Sigma_g^+$ states are the most intense features of the H_2^+- and He^+-impact spectra. Cross sections for the above-mentioned processes exceed 10^{-17} cm^2. (auth)

XUM

58754 MULTIPLE IONIZATION OF Ar BY 10-keV ELECTRONS AS A FUNCTION OF THE ENERGY LOSS. Van der Wiel, M. J.; Wiebes, G. (FOM-Instituut voor Atom- en Molecuulfysica, Amsterdam). Physica; 53: No. 2, 225-55(28 May 1971).

The small-angle inelastic scattering of 10-keV electrons in Ar was investigated in coincidence with the multiple ions formed. The range of energy losses —up to 400 eV —covers most processes of interest in both the M and the L shell. This study provides the general shape of the atomic oscillator-strength distributions for formation of the charge states one to four. By application of one of the sum rules for oscillator strengths, the results are found to be consistent with previous work on the impact-energy dependence of total ionization cross sections. A comparison is made with complementary information on multiple processes obtained from photoionization experiments and Auger electron spectroscopy. The evidence on shake-off transitions, occurring both in the initial excitation of the inner shell by the projectile electron and in the subsequent decay, is discussed. Furthermore, the measurements show that at energies between 40 and 80 eV a significant contribution to the double ionization in the M shell arises from doubly excited resonance states ($3s^1 3p^5 nl\ n'l'$) and from Ar^{2+}-excited continua ($3s^2 3p^3 nl$). (auth)

58755 GENERALIZED VARIATIONAL BOUNDS ON THE POSITRON-HYDROGEN REACTION MATRIX. Dirks, Johan Francis. Storrs, Conn.; Univ. of Connecticut (1970). 88p. University Microfilms Order No. 71-15,976.

Thesis.

The theory of generalized variational bounds is applied to the two-channel collisions of positrons with hydrogen leading to positronium formation. The formalism is developed in detail for this problem, and the zero-partial-wave solution is obtained in the coupled-static approximation. The nonlocal coupling kernels and the behavior of the wave functions are exhibited in detail. Eigenphase shifts and coupling parameters and the stripping and pickup cross sections as well as the elastic amplitudes for positron–hydrogen and positronium–proton collisions are studied as functions of scattering energies. A useful iteration procedure for solving the coupled equations with large coupling kernels is developed. Also, for the zero total partial wave, a reasonably complete treatment of this scattering system is presented, including a detailed discussion of the energy spectrum of the closed-channel Hamiltonian M. The coupling of the open channels to the closed channels gives rise to the effective interaction potentials, and these distortion terms are estimated variationally using the bound property of M. The orthogonality of M to the open-channel space is maintained by the presence of the energy-shift operator S, and the role of S is demonstrated in detail numerically, which produces essential cancellation of various terms. Partly because of the crudity of the trial functions used, resonance states below the first excitation threshold could not be found. Bounds on the diagonal K-matrix elements and eigenphase shifts are presented. (Diss. Abstr. Int., B)

58756 EXPERIMENTAL STUDY OF THE EFFECT OF VELOCITY AND OUTER-SHELL CONFIGURATION ON THE PROBABILITY FOR PRODUCING K VACANCIES IN VIOLENT ION–ATOM COLLISIONS AT keV ENERGIES. Fastrup, B.; Hermann, G.; Kessel, Q. C. (Univ. of Aarhus, Denmark). Phys. Rev. Lett.; 27: No. 12, 771-3(20 Sep 1971).

The probability for producing K vacancies in violent ion–atom collisions was found to depend not only on the impact parameter but also on the impact velocity and the number of vacancies in the atomic 2p subshells of the particles prior to the collision. This indicates that the K-electron promotion mechanism is different from the $L_{2,3}$-promotion mechanism determined for Z_1–Ar collisions. The K vacancies are almost exclusively produced in the lower-Z collision partner. (auth)

58757 VELOCITY CORRECTIONS FOR TOTAL SCATTERING CROSS SECTIONS. Lang, Neil C.; Lilenfeld, H. V.; Kinsey, James L. (Massachusetts Inst. of Tech., Cambridge). J. Chem. Phys.; 55: No. 7, 3114-15(1 Oct 1971).

Velocity correction factors are given for a quantity $\kappa_{eff} \equiv v_i Q_{eff}$, where Q_{eff} is an effective total scattering cross section as measured in a molecular-beam experiment, and v_i is the beam velocity. If κ_{eff} is regarded as being measured at the average relative velocity, the correction factors are all near unity and only weakly dependent upon the true velocity dependence of the cross section. (auth)

58758 DISSOCIATIVE EXCITATION OF O_2 IN THE VACUUM ULTRAVIOLET BY ELECTRON IMPACT. Ajello, Joseph M. (Univ. of Colorado, Boulder). J. Chem. Phys.; 55: No. 7, 3156-7(1 Oct 1971).

The emission cross section of the 1304-Å resonance triplet ($^3S^0 \rightarrow {}^3P$) of atomic oxygen produced by dissociative excitation of O_2 by electron impact was measured from threshold to 300 eV. The peak cross section is at 100 eV with a value of 3.00×10^{-18} cm^2. The relative emission cross section of the 1356-Å multiplet ($^5S^0 \rightarrow {}^3P$) of atomic oxygen was also determined. The peak cross section for the 1356-Å multiplet at 100 eV is at least 1.65×10^{-18} cm^2. (auth)

58759 EMISSION CROSS SECTIONS OF CO BY ELECTRON IMPACT IN THE INTERVAL 1260 TO 5000 A. I. Ajello, Joseph M. (Univ. of Colorado, Boulder). J. Chem. Phys.; 55: No. 7, 3158-68(1 Oct 1971).

Emission cross sections and band emission probabilities were measured for the fourth positive system ($A\ {}^1\Pi \rightarrow X\ {}^1\Sigma^+$) and the Cameron system ($a\ {}^3\Pi \rightarrow X\ {}^1\Sigma^+$) of CO and the first negative system ($B\ {}^2\Sigma^+ \rightarrow X\ {}^2\Sigma^+$) and the comet tail system ($A\ {}^2\Pi \rightarrow X\ {}^2\Sigma^+$) of CO^+ by electron-beam excitation of CO from threshold to 300 eV. Excitation cross sections were measured for C I, C II, and O I multiplets produced by dissociative excitation of CO. A comparison of the measured emission probabilities with theoretical values based on Franck–Condon factors for direct excitation was made. Molecular branching ratios were used to extend the optical calibration from the blackbody region to the vacuum ultraviolet. (auth)

58760 EMISSION CROSS SECTIONS OF CO_2 BY ELECTRON IMPACT IN THE INTERVAL 1260 TO 4500 A. II. Ajello, Joseph M. (Univ. of Colorado, Boulder). J. Chem. Phys.; 55: No. 7, 3169-77(1 Oct 1971).

A survey of the most prominent emission features produced by electron-impact excitation of CO_2 over the wavelength range of 1260 to 4500 Å has been completed. Emission cross sections were measured from threshold to 300 eV for the $\tilde{A}\ {}^2\Pi_u \rightarrow \tilde{X}\ {}^2\Pi_g$ and $\tilde{B}\ {}^2\Sigma_u^+ \rightarrow \tilde{X}\ {}^2\Pi_g$ electronic transitions of CO_2^+ produced by ionization excitation of CO_2. Emission cross sections were also measured for the $A\ {}^1\Pi \rightarrow X\ {}^1\Sigma^+$ electronic transition of CO and the $B\ {}^2\Sigma^+ \rightarrow X\ {}^2\Sigma^+$ electronic transition of CO^+ produced by dissociative excitation of CO_2. The vibronic intensities differed from those for electron excitation of CO. In addition, emission cross sections are presented for the $^3S^0 \rightarrow {}^3P$ 1304-Å multiplet of O I, the $^2D \rightarrow {}^2P^0$ 1335-Å multiplet of C II, and several atomic multiplets of C I produced by dissociative excitation of CO_2. The relative energy variations of the emission cross section of the $a\ {}^3\Pi \rightarrow X\ {}^1\Sigma^+$ electronic transition of CO and of the $^5S^0 \rightarrow {}^3P$ 1356-Å multiplet of O I were also measured. The processes leading to these emissions are discussed. (auth)

58761 COLLISION OF AN ATOM AND A DIATOMIC: THE ADIABATIC APPROXIMATION. Thiele, Everett; Katz, Ronnie (Johns Hopkins Univ., Baltimore). J. Chem. Phys.; 55: No. 7, 3195-3200(1 Oct 1971).

The adiabatic approximation is used to compute vibrational transition probabilities for the collision of an atom and a diatomic molecule in one dimension. The accuracy of the results is evaluated in terms of a parameter β, which is proportional to the period of the oscillator divided by the length of the collision. It is seen that, for small β, the error in adiabatic transition probabilities approaches zero and that the approximation is accurate over a physically interesting range of β. (auth)

58762 REACTION MATRIX METHOD FOR COMPUTING PROBABILITIES OF VIBRATION–TRANSLATION ENERGY TRANSFER: RANGE OF APPLICABILITY FOR THE COLLINEAR COLLISION OF AN ATOM AND A DIATOMIC. Clarke, James H.; Weare, John H.; Thiele, Everett (Johns Hopkins Univ., Baltimore). J. Chem. Phys.; 55: No. 7, 3201-5(1 Oct 1971).

Transition probabilities for the case of a collinear collision of an atom and a harmonic oscillator are computed using both the distorted-wave and K-matrix approximations. Results are shown as a function of a new parameter β, which incorporates the parameters E, m, and α of Secrest and Johnson and which is proportional to the ratio of the oscillator period divided by the collision time. Ranges of applicability for the above approximate methods are discussed in terms of β for one- and two-quanta transitions. The K-matrix approach is seen to extend the range of β for which the distorted-wave approximation maintains a given degree of accuracy for one-quantum transitions. Also the K-matrix method yields vastly improved results for two-quanta transitions which exhibit the same type of dependence on β as the one-quantum-transition probabilities. (auth)

58763 DETERMINATION OF THE ABUNDANCE OF EXCITED O^+ IONS IN BEAMS PRODUCED BY ELECTRON IMPACT ON O_2, CO_2, N_2O, NO_2, AND H_2O. Hughes, B. M.; Tiernan, T. O. (Aerospace Research Labs., Wright-Patterson AFB, Ohio). J. Chem. Phys.; 55: No. 7, 3419-26(1 Oct 1971).

The fraction of excited ions present in O^+ ion beams produced by impact of 60-eV electrons on various oxygenated molecules was determined approximately 23 μsec after formation. The technique employed involves the measurement of apparent rate coefficients for charge-transfer reactions of O^+ to N_2 and CO at very low kinetic energies (~0.3 eV) in a tandem mass spectrometer. Under these conditions, charge transfer of $O^+(^4S)$ is endothermic and the formation of N_2^+ and CO^+ products is due solely to excited O^+ ions in the reactant beam. By normalizing the rate coefficients for the reactions of O^+ from the several sources to that for an O^+ beam for which the excited ion abundance is known, the fractional abundance of O^{+*} in each of the respective ion beams is calculated. These fractions for O^+ beams from the indicated sources were found to be: CO_2, 0.04; N_2O, 0.43; NO_2, 0.34; H_2O, 0.90. The fractional abundance data are utilized for the study of the reactions of both ground-state and excited-state O^+ with Ar and Kr. Ground-state $O^+(^4S)$ was found to be completely unreactive with Ar even at ion kinetic energies up to 170 eV. The cross section for charge transfer from excited O^+ ions to Ar is quite small at very low kinetic energies but increases sharply at energies above $E_{lab} \sim 20$ eV. Both $O^+(^4S)$ and $O^+(^2D)$ undergo charge transfer to Kr over the energy range investigated and a maximum is observed in the cross section for the $O^+(^4S)$ reaction. The results are qualitatively consistent with the adiabatic hypothesis for nonresonant charge transfer. (auth)

58764 KINETIC ENERGIES OF IONIZATION PRODUCTS FROM COLLISIONS OF Ar–Ar AND He–He BELOW 150 eV c.m. ENERGY. Hammond, R. H. (Brown Univ., Providence); Henis, J. M. S.; Greene, E. F.; Ross, John. J. Chem. Phys.; 55: No. 7, 3506-15(1 Oct 1971).

Measurements have been made of the energy spectra of ions and electrons produced in the collision of beams of neutral Ar of given energy (laboratory energy range 57 to 240 eV) with a gas of Ar and of neutral He (145 to 300 eV) with a gas of He. The energy dependence of the total cross section for ionization is consistent with previous results. The electron spectra from collisions of Ar + Ar show peaks at 0, 6, and ~9 eV. From this it is estimated that about 15% of the Ar^+ ions produced come from autoionizing states of Ar. For certain ranges of initial relative energy Ar – Ar ionization occurs mostly in backscattering collisions. An analysis of the ion spectra of experiments at these initial relative energies (greater than 33 eV), made with a simple model, shows that most ions are produced by two curve crossings 12 ± 2 eV and 22 ± 1 eV above the ionization potential (15.8 eV). (auth)

58765 DISSOCIATION OF CO_2 BY ELECTRON IMPACT WITH THE FORMATION OF METASTABLE $CO(a^3\Pi)$ AND $O(^5S)$. Freund, Robert S. (Bell Telephone Labs., Inc., Murray Hill, N. J.). J. Chem. Phys.; 55: No. 7, 3569-77(1 Oct 1971).

Molecular-beam time-of-flight measurements show that CO_2 is dissociated by electron impact to give two metastable fragments, $CO(a\ ^3\Pi)$ and $O(^5S)$. The experimental dissociation limit for production of $CO\ (a\ ^3\Pi)$ lies at 11.65 ± 0.30 eV, which agrees with the 11.45-eV energy of $CO_2 \xrightarrow{e} CO(a\ ^3\Pi) + O(^3P)$. The excitation function for production of $CO(a\ ^3\Pi)$ shows structure that can be correlated with dissociation processes involving higher triplet states of CO and excited states of O. The cross section for formation of $CO(a\ ^3\Pi)$ has a maximum at 27 ± 1 eV, a magnitude 0.4 ± 0.2 times the maximum cross section for $CO \xrightarrow{e} CO(a\ ^3\Pi)$, and a value probably not far from 4×10^{-17} cm^2. (auth)

58766 GLAUBER AMPLITUDES IN CHARGED-PARTICLE–HYDROGEN-ATOM COLLISIONS. Thomas, Brian K.; Gerjuoy, E. (Univ. of Pittsburgh). J. Math. Phys. (N. Y.); 12: No. 8, 1567-76(Aug 1971).

The Glauber scattering amplitudes for the excitation of the ns and np levels of atomic hydrogen by electrons (or protons) incident upon the ground state were obtained in closed form. In contradistinction to previously quoted results, these new expressions require no numerical integration. For small n, the amplitudes reduce to simple sums of hypergeometric functions. Hence the Glauber amplitudes for these transitions now can be computed with scarcely more difficulty than the Born amplitudes. A selection rule for arbitrary transitions is derived. (auth)

58767 THEORY OF ANOMALY OF THE DIFFERENTIAL SCATTERING CROSS SECTIONS FOR HIGH-ENERGY ATOMS IN THE PRESENCE OF AN INELASTIC PROCESS. Kotova, L. P.; Ovchinnikova, M. Ya. (Inst. of Chemical Physics, Moscow). Zh. Eksp. Teor. Fiz.; 60: No. 6, 2026-39(Jun 1971). (In Russian).

The shape of the differential scattering cross sections (elastic and inelastic) for high-energy atoms is investigated in the presence of an inelastic process involving quasi intersection of terms. It is shown that oscillations of the inelastic cross section at angles exceeding the threshold value τ_{II} is due to interference of contributions from two trajectories. Parameters of the scattering functions contributing to the process and also some potential parameters can be determined on the basis of the experimental oscillation phase. It is shown that in a certain angular range ($\tau_{II}^{\gamma} < \tau < \tau_0$) the elastic cross section near the beginning of the cross-section anomalies is the result of interference of contributions of three trajectories (or three scattering-function branches); at larger values ($\tau > \tau_0$) the cross section results from interference of two scattering trajectories. Quasi-classical expressions are obtained, which are replaced by quantum expressions in the vicinity of the threshold angles τ_{II}, τ_{II}^{γ} and angle τ_0 corresponding to the term intersection radius R_0. The calculated shape of the elastic cross section, in which a certain approximation of the scattering function is employed, qualitatively agrees with the experiments and permits formulation of a prescription for determination of the term intersection radius R_0 on basis of the elastic-cross-section experimental curves. (auth)

58768 CHARGE-CHANGING CROSS SECTIONS FOR HEAVY IONS IN COMPLEX MOLECULES: THE FAILURE OF AN ADDITIVE RULE. Wittkower, A. B. (High Voltage Engineering, Burlington, Mass.); Betz, H. D. J. Phys., B (London); 4: No. 9, 1173-5(Sep 1971).

Electron-capture and -loss cross sections were measured for 12-MeV iodine ions passing through H_2, N_2, O_2, CO_2, N_2O, CH_4, and $(CH_2)_3O$. It is shown that, in contrast to recent data for fast hydrogen beams, it is not possible in this case to predict the cross sections in a complex molecular target by summing contributions from the measured cross sections of its constituent atoms. (auth) (UK)

58769 MEASUREMENT OF THE CROSS SECTIONS FOR ELECTRON-IMPACT IONIZATION OF MULTI-ELECTRON IONS. II. N^{2+} TO N^{3+} AND C^+ TO C^{2+}. Aitken, K. L.; Harrison, M. F. A.; Rundel, R. D. (United Kingdom Atomic Energy Authority, Abingdon, Eng.). J. Phys., B (London); 4: No. 9, 1189-99(Sep 1971).

Absolute measurements were made of the electron-impact ionization cross sections for the reaction $N^{2+} + e \rightarrow N^{3+} + 2e$ and its isoelectronic partner $C^+ + e \rightarrow C^{2+} + 2e$. The technique of crossed beams was employed, and, at incident electron energies in excess of about 100 eV, the cross section for N^{2+} can be expressed by $Q = (567\ E)lg(E/51.0)/(10^{-17}\ cm^2)$ and that for C^+ by $Q = (1060/E)lg(E/31.5)/(10^{-17}\ cm^2)$, where E is in eV. Measurements were extended to energies below threshold and the presence of metastable ions was observed; their influence upon the measured cross sections is discussed. The present experimental data are compared with Coulomb – Born calculations by Moores, classical binary-encounter calculations by Thomas and Garcia (1969), and a semiempirical estimate by Lotz (1968). (auth)(UK)

58770 EVALUATION OF TRANSITION MATRIX ELEMENTS FOR MULTIPHOTON PROCESSES IN ATOMIC HYDROGEN. Karule, K. (Inst. of Physics, Riga). J. Phys., B (London); 4: No. 9, L67-70(Sep 1971).

A method is proposed to calculate Nth-order bound – bound and bound – free radial transition matrix elements for multiphoton processes in atomic hydrogen in the nonrelativistic dipole approximation. The analytical expressions for these transition matrix elements are derived. (auth) (UK)

58771 LOW-ENERGY ATOMIC COLLISIONS. II. FORMAL THEORY OF H^+–H COLLISIONS. Kouri, Donald J. (Univ. of Houston, Tex.); Curtiss, C. F. Mol. Phys.; 21: No. 4, 609-33 (1971).

The Schrödinger equation for the system H^+ – H developed in a previous paper (1966) is considered using new expansion functions for electronic states obtained from H_2^+ molecular ion electronic eigenfunctions by a unitary transformation. These new functions have the advantage of remaining orthonormal at all internuclear separations and asymptotically becoming symmetrized atomic hydrogen states. Although they are eigenfunctions of the H_2^+ hamiltonian only in the limit of large internuclear distance, the effect of the H_2^+ hamiltonian on these functions is readily found. Because of coupling that remains nonzero in the limit of large interproton distance, each independent formal solution of the H^+ – H equations involves more than one expansion state in this limit. These solutions may be expressed asymptotically as column vectors multiplied by incoming or outgoing spherical waves. The formal theory of scattering as developed by Gell – Mann and Goldberger has been utilized along with the projection formalism of Feshbach to obtain the correct asymptotic form of the scattering wave function. It is shown that coefficients of all outgoing spherical waves cannot be interpreted as scattering amplitudes. In addition, new interference

XUM

phenomena are found to result from the presence of the infinite-ranged coupling. The present formalism is shown to reduce to the usual perturbed-stationary-states method in the approximation that the infinite-ranged coupling is neglected. (auth) (UK)

58772 ITERATIVE PERTURBATION SOLUTION OF THE INVERSE POTENTIAL PROBLEM. **Bottcher, C. (Harvard Coll. Observatory, Cambridge, Mass.). J. Phys., B (London): 4: No. 9, 1140-9(Sep 1971).**

A method is suggested for systematically obtaining model potentials that accurately reproduce spectroscopic or scattering data. Applications are made to atomic systems consisting of one electron outside a closed shell for the closed shells Li^+, Na^+, K^+, He, and Ne. (auth) (UK)

58773 ANGULAR DISTRIBUTION OF PRODUCTS OF REACTIONS PROCEEDING THROUGH FORMATION OF A LONG-LIVED COMPLEX. **Nikitin, E. E.; Rusin, L. Yu. (Inst. of Chemical Physics, Moscow). Dokl. Akad. Nauk SSSR; 198: No. 2, 330-2(11 May 1971). (In Russian).**

The method of crossed molecular beams may be used to study angular distribution of particles for elastic and inelastic collisions. The theoretical calculations of angular distribution present a difficult problem, requiring a large expenditure of machine time because of insufficient knowledge regarding intra- and intermolecular interactions. The problem may be simplified by limiting it to processes proceeding through the formation of complexes, the lifetimes of which are substantially greater than the period of rotation of a molecule. A statistical approximation is employed. The final result does not describe the resonance structure of scattering, but the differential cross section is equal to the sum of the potential scattering and the scattering through the complex. (K.S.W.)

58774 MEASUREMENT OF THE CROSS SECTIONS FOR ELECTRON-IMPACT IONIZATION OF MULTI-ELECTRON IONS. I. O^+ TO O^{2+} AND O^{2+} TO O^{3+}. **Aitken, K. L.; Harrison, M. F. A. (United Kingdom Atomic Energy Authority, Abingdon, Eng.). J. Phys., B (London); 4: No. 9, 1176-88(Sep 1971).**

The technique of crossed electron–ion beams was used to make absolute measurements of the electron-impact ionization cross section for the reaction $O^+ + e \rightarrow O^{2+} + 2e$. Incident electron electron energies ranged from below threshold up to 1000 eV, and at energies above 100 eV the cross section can be expressed as $Q = (1530/E)\lg(E/55.0)(10^{-17}\ cm^2)$, where E is the electron impact energy in eV. A similar measurement for $O^{2+} + e \rightarrow O^{3+} + 2e$ up to an incident energy of 500 eV yields the expression $Q = (626/E)\lg(E/55.0)(10^{-17}\ cm^2)$. Evidence for the presence of metastable oxygen ions in the parent ion beams is presented and their influence on the measured cross sections discussed. The experimental results are compared with a Coulomb–Born calculation by Moores, a classical binary-encounter calculation by Thomas and Garcia (1969), and a semiempirical estimate by Lotz (1968). Comparison of the present measurements for O^+ with the ionization cross section of the isoelectronic nitrogen atom supports the measurements of Smith et al. (1962) for this atom. A comparison is also made between O^{2+} and its isoelectronic ion N^+. (auth) (UK)

58775 HIGH-ENERGY TREATMENT OF ATOMIC COLLISIONS. **Dettmann, Klaus (Technische Hochschule, Aachen). Springer Tracts Mod. Phys.; 58: 119-206(1971).**

The basic theory for a high-energy treatment of atomic collisions is established. Potentials and masses are not specified so that nuclear scattering is also included. A wave-packet theory for direct and rearrangement collisions is set up. In a separate chapter, this theory is applied to Coulomb scattering. The impact-parameter treatment is formulated and justified for a one-dimensional model. The leading term of the high-energy expansion for the differential and total cross sections for three-particle collisions is calculated. Calculation of the total inelastic and charge-exchange cross sections for proton–hydrogen collisions is used an as example. The Schwinger variational principle for the T-matrix of direct and rearrangement collisions is formulated. (46 references) (A.G.W.)

58776 ISOTOPE DEPENDENCE IN K, L, AND M SHELL IONIZATION CROSS SECTIONS BY $^3He^+$ AND $^4He^+$ BOMBARDMENTS. **Shima, Kunihiro (Hiroshima Inst. of Tech.); Makino, Isao; Sakisaka, Masakatsu. J. Phys. Soc. Jap.; 31: No. 4, 971-6(Oct 1971).**

The ionization cross sections of Al K, Cu L, Mo L, Ag L and W M shells are presented for the incident $^3He^+$ and $^4He^+$ ions in the energy range from 45 to 90 keV/amu. The cross sections were evaluated from the experimentally obtained thick-target yields of characteristic x rays, referring to the semiempirical stopping-power data of helium ions. Contrary to the prediction by the Born approximation, isotope dependence was clearly ascertained in the ionization of target atoms. The quantitative analysis for Al K-shell ionization has shown that the collision process can be explained by the "binding theory." The isotope dependence is mainly attributed to the Coulomb deflection difference of the isotopic projectiles near the target nucleus. (auth)

58777 IONIZATION CROSS SECTIONS OF Ca, Sr, AND Ba BY ELECTRON IMPACT. **Okuno, Yasuko (Tokyo Univ.). J. Phys. Soc. Jap.; 31: No. 4, 1189-95(Oct 1971).**

Total ionization cross sections of Ca, Sr, and Ba by electron impact were measured by the crossed-beam technique. The intensity of the neutral atomic beam is determined by the deposition method. Sample atoms deposited onto a beam collector are quantitatively analyzed by atomic absorption spectrophotometry. The absolute cross sections are determined to be 6.2 ± 0.2 Å^2 at 13.6 eV for Ca and 7.2 ± 0.3 Å^2 at 12.6 eV for Sr. The absolute cross section of Ba could not be determined because of poor sensitivity of the spectrophotometer for Ba. Possible systematic errors are estimated to be between +8% and −19% for both Ca and Sr. Relative cross sections of the three elements are obtained for electron energies from 0 to 1000 eV. Each curve for the total ionization cross section as a function of electron energy has two maxima in the low-energy region, one of which is considered to be due to autoionization. The results are compared with some experimental results and theoretical calculations by other workers. (auth)

58778 DIFFERENTIAL CROSS SECTION FOR THE REACTIVE SCATTERING OF DEUTERIUM ATOMS BY HYDROGEN MOLECULES: CROSS SECTIONS FOR THE EXCITATION OF $Na(3^2P)$ BY COLLISIONS WITH INTERNALLY EXCITED MOLECULAR HYDROGEN, DEUTERIUM, AND NITROGEN. **Krause, Herbert Francis. Pittsburgh; Univ. of Pittsburgh (1970). 258p. University Microfilms Order No. 71-17,689.**

Thesis.

The reaction $D + H_2 \rightarrow HD + H$ was investigated in a modulated cross-beam experiment utilizing thermal-energy beams. The differential scattering cross section for reactively formed HD was measured and the mean velocity of detected HD was determined via phase spectrometry. These measurements indicate that reactive collisions in the vicinity of the reaction threshold are of the direct type with the HD generally preferring to be scattered in a direction anti-parallel to that of the attacking atom without significant internal excitation. For the purpose of calibrating this cross section absolutely, the differential cross section for $D + H_2 \rightarrow D + H_2$ was studied and normalized to the known total cross section. The reactive cross section was estimated to be of order 2 Å^2 by comparing differential signals of the reactive and elastic processes. The empirical results of this study are in general agreement with theoretical calculations performed by Micha and Karplus et al. In another series of experiments, the collisional excitation of $Na(3^2P)$ by H_2, D_2, and N_2 was studied using modulated thermal-energy crossed beams, and sodium D radiation was detected. In one configuration the effective excitation rate constants for these molecules were determined and these rates were studied as a function of molecular-beam temperature. In a second configuration the molecular beam was velocity-selected, and the production of $Na(3^2P)$ was observed as a function of molecular-beam velocity and temperature. Excitation cross sections determined as a function of initial molecular vibrational state for translational and vibrational temperatures of order 1500°K and 3000°K indicate that excitation is most efficient when the electronic energy is supplied purely by molecular internal energy. The energy transfer efficiency is smaller by about one order of magnitude when molecular internal energy and the kinetic energy of collision couple to supply the energy of excitation. Effective cross sections for the inverse process derived from excitation cross sections via microscopic reversibility are in agreement with those determined in quenching studies carried out at high temperatures. Results for N_2 are in general agreement with the theory of Bauer, Fisher and Gilmore and slightly poorer agreement with the theory of Bjerre and Nikitin. (Diss. Abstr. Int., B)

58779 EXCITATION OF THE AUTO-IONIZATION LEVELS OF He BY COLLISION WITH A HEAVY PARTICLE FOR MEDIUM ENERGIES (10 TO 130 keV). **Bordenave-Montesquieu, Alain; Benoit-Cattin, Pierre (Univ., Toulouse). Compt. Rend., Ser. B; 272: No. 26, 1473-6(28 Jun 1971). (In French).**

The energy spectra of the electrons stripped from auto-ionized helium atoms by heavy (H_1^+, H_2^+, H_3^+) fast (10- to 130-keV) particles were determined. In proton–He collisions the first terms of the singlet series $2sns\,^1S$, $2pnp\,^1S$, and sp, $2n+\,^1P$ were identified; in addition the asymmetry of the $2s2p\,^1P$ peak was demonstrated. (auth) (France)

58780 POLARIZATION OF THE H_β LINE EMITTED IN $Li^+ + H_2$ COLLISIONS. Carre, M.; Desesquelles, J.; Gaillard, M. (Univ., Lyon). Compt. Rend., Ser. B; 273: No. 1, 12-14 (5 Jul 1971). (In French).

Polarization of the H_β line emitted in the dissociation of the H_2 molecule bombarded with 10- to 110-keV Li^+ ions was observed. The polarization rate measured is compatible with that obtained from the theory of Van Brunt and Zare. (auth) (France)

58781 TOTAL EFFECTIVE SCATTERING CROSS SECTIONS OF THE HD-INERT GAS SYSTEMS IN THE THERMAL ENERGY REGION. Butz, H. P.; Feltgen, R.; Pauly, H.; Vehmeyer, H.; Yealland, R. M. (Max-Planck-Institut fuer Stroemungsforschung, Goettingen, Ger.). Z. Phys.; 247: No. 1, 60-9(1971). (In German).

Total cross sections of velocity-selected HD beams scattered by the inert gases in a scattering chamber were measured in the velocity range from 300 to 3500 m/sec. No effects of the HD asymmetry are visible; the potential parameters obtained are, to within the error limits, the same as those for scattering of H_2 and D_2 by inert gases. The glory structure of all three scattering systems can be fitted relatively well using the Lennard-Jones (12,6) potential. This does not necessarily provide valid information about the actual potential shape for these systems, it can also be a result of the small "potential well capacity" parameters B of these systems, since for decreasing B values the absolute glory amplitude becomes more and more insensitive to potential shape changes, as can be seen from both semiclassical and exact calculations. (auth)

58782 TOTAL EFFECTIVE CROSS SECTIONS FOR THE SCATTERING OF He, HD, AND D_2 BY SEVERAL MOLECULES. Butz, H. P.; Feltgen, R.; Pauly, H.; Vehmeyer, H. (Max-Planck-Institut fuer Stroemungsforschung, Goettingen, Ger.). Z. Phys.; 247: No. 1, 70-83(1971). (In German).

The measured velocity dependence of the total scattering cross section for the scattering of He, HD, and D_2 by the molecules CH_4, N_2, O_2, NO, CO, HD, and D_2 can be described relatively well by a Lennard-Jones (12,6) potential. Only for the systems with a CO_2 target are large deviations from the L-J (12,6) predictions found; the measured glory amplitudes are considerably smaller. The deformation of the spherically symmetric potential that must be made in order to fit the CO_2 glory pattern is given. Furthermore, the CO_2 systems were calculated using an angle-dependent L-J (12,6) potential, taking into account only elastic processes. The agreement with the measurements is good. (auth)

Atomic Theory

58783 INTERNATIONAL SYMPOSIUM ON THE THEORY OF ATOMIC STRUCTURE, GIF-SUR-YVETTE, FRANCE, 8–11 JULY 1970. J. Phys. (Paris), Colloq.; 31: No. 11-12, C.1-239(Nov-Dec 1970). (In French and English). (CONF-700718).

Twenty-one separate papers were abstracted. Symmetry and atomic structure, correlations and radial wave functions, transition probabilities, and relativistic corrections were investigated. (France)

For abstracts of individual papers see: 58684, 58696, 58697, and 58784–58801.

58784 USE OF REFLECTION SYMMETRY IN ATOMIC THEORY. Jucys, A. P. J. Phys. (Paris), Colloq.; 31: No. 11-12, C.3-7(Nov-Dec 1970). (In French).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The symmetry relations for the Clebsch–Gordan coefficients of the angular momentum theory and those for the matrix elements of the irreducible tensor operators containing the transpositions as well as the mirror reflections are presented. The annihilation operator of an electron was interpreted as that of creation completely reflected. This reflection consists of a mirror reflection of the coordinate system and of the space with respect to the xy plane. The seniority quantum number ν of Racah must be replaced by $\nu = 41 + 4 - \nu$ for the almost closed shell of electrons. (auth) (France)

58785 SECOND USE FOR THE GROUP G_2. Judd, B. R. (Johns Hopkins Univ., Baltimore). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.9-16(Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The group G_2, when used for f electrons, exhibits many unusual and surprising features. In an effort to understand them, the use of G_2 is studied for the p + h shell. The L structure of the irreducible representations (30) and (22) becomes apparent. Analogues are found of the celebrated null 6-j symbol associated with the existence of G_2 in the f shell. The vanishing of the matrix elements of the spin– orbit interaction between F and G states that belong to (21) is understood in terms of simple selection rules on the quasiparticle angular momenta I^h and I^p of the h and p electrons. The operators Ω and χ_2 that Racah introduced for studying the Coulomb interaction within the f shell are shown to be complementary in that they are the only two operators required to express the eigenvalues of $I^h \cdot I^p$ for (21). Properties of the p + h shell are analyzed, particularly the necessity for introducing complex phases in the quasi-particle description. (auth) (France)

58786 GROUP PROPERTIES OF RADIAL WAVE FUNCTIONS. Armstrong, L. L. (Johns Hopkins Univ., Baltimore). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.17-23(Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The noncompact group O(2,1) is used in an investigation of hydrogenic radial wave functions. These radial functions are shown to form bases for infinite dimensional representations of the algebra of O(2,1). It is found that r^N and r^{-N} (N positive) transform as tensors with respect to this algebra. Analysis of matrix elements of r^N and r^{-N} shows that the Wigner–Eckart theorem is valid for this group and that the pertinent Clebsch–Gordan coefficients are proportional to the familiar R(3) Clebsch–Gordan coefficients. This porportionality provides simple explanations of the selection rules for hydrogenic radial matrix elements noted by Pasternack and Sternheimer, and the proportionality of hydrogenic expectation values of r^N and r^{-N} to $3 - j$ symbols. (auth) (France)

58787 STUDY OF $(d + s)^n p^m$ CONFIGURATIONS USING THE SU_3 GROUP. Feneuille, S. (CNRS, Orsay, France); Crubellier, A.; Haskell, T. J. Phys. (Paris), Colloq.; 31: No. 11-12, C.25-32(Nov-Dec 1970). (In French).

From International symposium on the theory of atomic structure; Giz-sur-Yvette, France (8 Jul 1970). See CONF-700718.

A new scheme, based on SU_3 and using Elliott's results on $(d + s)^n$ configurations, is given for studying $(d + s)^n p^m$ configurations. It is shown in some particular cases that SU_3 is not really a good approximate symmetry for the considered configurations; however, this scheme is very useful for calculating matrix elements of operators generally used in atomic spectroscopy. To emphasize this point, the properties of one-particle operators concerning s, d, and p electrons are specified in this classification and a complete set of symmetrized, scalar, hermitian spin-independent two-particle operators, acting within $(d + s)^n p^m$ configurations and having well-defined symmetry properties, is constructed explicitly. (auth) (France)

58788 SYMMETRY PRINCIPLES IN ATOMIC SPECTROSCOPY. Wybourne, B. G. (Univ. of Canterbury, Christchurch, N. Z.). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.33-9(Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

It is suggested that while the theory of compact groups leads to an elegant mathematical formalism for calculating the properties of many-electron systems, it does not lead to a physically significant interpretation of these properties. The desirability of applying noncompact groups to many-electron systems is discussed. As a preliminary study, the tensor operator algebra of SO(4) is developed using the known SO(4) vector coupling coefficients which in turn are used to study the canonical chain $SO(5) \supset SO(4) \supset SO(3) \supset SO(2)$ which finds a physical realization in the dynamical symmetry of the bound states of the hydrogen atom. These results are then extended to the representations of the noncompact de Sitter group SO(4,1) constructed on the canonical basis $SO(4,1) \supset SO(4) \supset SO(3) \supset SO(2)$. The possibility of applying the theory of noncompact groups to many-electron atoms is then considered. (auth) (France)

58789 REDUCED MATRIX ELEMENTS AND REPRESENTATION OF WAVE FUNCTIONS. Innes, F. R. (Air Force Cambridge Research Labs., Bedford, Mass.). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.43-6(Nov-Dec 1970).

From International Symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

An extension is suggested from wave function representations with a minimal set of intermediate terms, treeform or dendritic in structure, to simply polygonal or more elaborate structures,

XUM

with a larger number of intermediates. These representations are maintained without explicit reference to axis orientation, in quasi spin, spin, and angular spaces. In the treatment of a single shell, a fermion operator, multilinear in general, must occur at each vertex of the representation. The vertex coefficients are then submatrix elements of these operators, or coefficients of fractional parentage for the appropriate structures. Here it is useful to introduce a small submatrix element for the study of the coefficients. It is also convenient to adopt an ordering of terms with the use of quasi-spin and spin weights particularly for assignment of phases. The p-shell provides a few instances of number-free parentage coefficients with properties relating to adjoint and complement. (auth) (France)

58790 S-FUNCTIONS AND SYMMETRY IN PHYSICS. Butler, P. H. (Univ. of Canterbury, Christchurch, N. Z.). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.47-50 (Nov-Dec 1970).

From International Symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

A comprehensive set of computer programs for the extensive calculation of the character theory of groups was developed. Using the algebra of S functions, it was possible to calculate Kronecker products or branching rules within the compact continuous groups U_n, O_n, R_n, Sp_n, and G_2. A straightforward systematic method of calculating outer plethysms and its use in calculating continuous group properties is discussed. The operation of the inner plethysm may be used to calculate similar properties of finite groups. The systematic evaluation of this operation by a method that does not require the use of character tables is also discussed. (auth) (France)

58791 SPATIAL EIGENFUNCTIONS OF THE SPIN-INDEPENDENT MANY-ELECTRON HAMILTONIAN. Musher, J. I. (Univ. of Yeshiva, New York). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.51-67 (Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The symmetry properties of the spatial eigenfunctions of the spin-independent many-electron Hamiltonian are examined and their eigenvalues and degeneracies are discussed along with eigenvalues of the corresponding physical wave functions. Detailed examples are given, mostly for the three-electron problem, with certain properties of the level structure of a given configuration and the ordering of such levels generalized to the many-electron problem. The use of nonsymmetric perturbation theoretic procedures for calculating the spatial eigenfunctions is discussed, and the potential utility of such procedures is considered. (auth) (France)

58792 STABILITY OF SELF-CONSISTENT SYMMETRIES IN ATOMIC THEORY. Prat, R. F. (Paris Univ., Orsay, France). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.69-70 (Nov-Dec 1970). (In French).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

Spherical symmetry is self-consistent only in complete shells states. However, a spherical solution need not be stable unless it is an absolute minimum, although this can never be proved. A search for deformed variational solutions was undertaken; with the neon atom, spherical symmetry appears as one of the results of a Roothaan-type analytic calculation based on Bagus' set of s- and p-only Slater orbitals. (auth) (France)

58793 THEORY OF ELECTRON CORRELATION IN GROUND AND EXCITED STATES WITH APPLICATION TO ATOMIC PROPERTIES. Sinanoglu, O. (Yale Univ., New Haven). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.83-8 (Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

. Various ways of introducing electron correlation into atomic structure theory are briefly examined. It is shown that the pair correlation theory of Sinanoglu et al., applies mainly to closed shells, and at best, to a few open-shell ground states. Electron correlation of both the energy and wave function of a many-electron atom in an excited state displays very different behavior; such behavior can be explained by a recent theory. A summary of the essential points in the theory of excited states is given. Applications to electron affinities, excitation energies, and transition probabilities are presented. The results obtained are compared with the most recent experimental data. (auth) (France)

58794 MANY-BODY THEORY FOR HYPERFINE EFFECTS IN ATOMS AND MOLECULES. Das, T. P.; Dutta, C. M.; Dutta, N. C. (Univ. of Utah, Salt Lake City). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.99-104 (Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

Results from the application of linked-cluster many-body perturbation theory to atomic hyperfine constants are reviewed. As a specific example of the application of this procedure to molecular systems, the problem of the indirect nuclear spin–spin coupling constant of the HD molecule was studied. The complete set of states were the exact bound and continuum states of the H_2^+ molecular ion with the same internuclear separation as for the H_2 molecule. The calculated value of J_{HD} by the Fermi contact interaction mechanism is +42.57 Hz; the most recent experimental value is +42.7 ± 0.7 Hz. (auth) (France)

58795 EXTENSION OF THE HYLLERAAS EXPANSION FOR THE HELIUM GROUND STATE. Somerville, W. B. (University Coll., London). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.107-9 (Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

In the work of Hylleraas, variational terms containing only integer powers of $(r_1 + r_2)$, $(r_1 - r_2)$, and r_{12} were used. H. M. Schwartz introduced half-integer exponents. The use of general real number exponents is discussed here. The first results suggest that the method could be of value. (auth) (France)

58796 THE PSEUDO-ATOM: A SOLUBLE MANY-BODY PROBLEM. Moshinsky, M.; Novaro, O.; Calles, A. (Univ. Mayor de San Andres, La Paz, Bolivia). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.125-40 (Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

If relativistic effects are disregarded, an atom of more generally, an ion of charge Z can be considered as a system of n fermions of spin $\frac{1}{2}$ in an attractive Coulomb potential interacting through a repulsive Coulomb force. As this problem cannot be solved when $n > 1$, a large number of approximation techniques have been put forward. The common Coulomb potential is replaced by an attractive harmonic oscillator, and the interacting force by a repulsive harmonic oscillator. The resulting model, which can be called a pseudo-atom, can be solved exactly for any value of n. Approximation procedures based on perturbation, variation, Hartree–Fock methods, variance, density matrix, etc are then applied to the problem. The convergence of all these methods to the exact energy and wave function is discussed, first when $n = 2$ electrons, and then for closed shell-pseudo-atoms with up to 112 electrons. (auth) (France)

58797 WHY THE HARTREE–FOCK F^k INTEGRALS ARE TOO LARGE. Fred, M. (Argonne National Lab., Ill.). J. Phys. (Paris), Colloq.; 31: No. 11-12, C. 161-2 (Nov-Dec 1970).

From International symposium on the theory of atomic structure; Giv-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The F^k integrals evaluated from Hartree–Fock (HF) radial eigenfunctions are usually about 50% larger than those derived experimentally, a fact ascribed to the neglect of configurational interaction and other effects in the HF calculation. As a complete theory is difficult, it is useful to consider the properties of the HF solutions more directly. Slater has discussed the nonhydrogenic relation between the eigenvalue and the size of the function: the effective Z for the function is larger than the effective Z for the energy. The ratio of $\langle 1/r \rangle$ evaluated for the two Z values reproduces the calculated/experimental F^k ratio. Hence, the functions cannot be used directly as a measure of energy; they may, however, be simply corrected. (auth) (France)

58798 EVALUATION OF EFFECTIVE OPERATORS FOR CONFIGURATION INTERACTION. Morrison, J.; Kajnak, K.; Wilson, M. (Argonne National Lab., Ill.). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.167-71 (Nov-Dec 1970).

From International Symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

Corrections to the Hartree–Fock–Slater integrals due to electrostatic configuration interaction are calculated for the $4\,f^2$ configuration of Pr IV using perturbation theory and graphical methods. The Trees parameter α, and the additional parameters β, and γ are also calculated. In the second order, the interaction with 27 bound configurations, and 8 single-particle excitations to the continuum gives $F^2 = 88\,963{,}14$, $F^4 = 61\,000.08$, $F^6 = 33\,353{,}80$. This may be compared with the empirical values $F^2 = 72\,549$, $F^4 = 53\,874$, $F^6 = 35\,973$, $\alpha = 24$, $\beta = -586$, and $\gamma = 728$. (auth) (France)

58799 RELATIVISTIC ATOMIC HAMILTONIAN. Wadzinski, H. T. (CNRS, Orsay, France). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.213-19 (Nov-Dec 1970).

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

The relativistic hamiltonian for a multi-electron atom is presented in such a way as to render explicit the assumptions and approximations made. The basic assumptions made are the validity of quantum electrodynamics, the possibility of using effective potentials to reduce the quantum electrodynamics to a hamiltonian form. Ambiguities in the potential obtained for the first-order interaction are discussed. Another source of difficulty is the precise definition of the position variables, which must be used in investigations of internal and external interactions. These results enable the construction of a hamiltonian for nuclei with well-defined spins. However, it is preferable to use a nonrelativistic treatment for the motion of the nucleus; such a treatment leads to a phenomenological description of the nuclear moments, which is valid for any spin. (auth) (France)

58800 RELATIVISTIC ATOMIC WAVE FUNCTIONS FOR OPEN SHELLS. **Mayers, D. F. (Oxford Univ.). J. Phys. (Paris), Colloq.; 31: No. 11-12, C.221-4(Nov-Dec 1970).**

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

A simple method of adapting the relativistic Hartree–Fock approximation to configurations involving open shells is described. A shell with angular quantum number j splits relativistically into subshells with $j = 1 + \frac{1}{2}$ and $j = 1 - \frac{1}{2}$, and the electrons can distribute themselves between these subshells in several different ways, giving rise to several different configurations, having very nearly equal energies. The idea of an average of configurations is extended to give a weighted average of all the terms arising from all these configurations. The Hartree–Fock wave functions are then determined for this average configuration; the full Hamiltonian matrix can then be determined, and the energy level scheme found. Results are given for the $(2p)^3$ ground configuration of nitrogen. (auth) (France)

58801 DETERMINATION OF EIGENFUNCTIONS OF THE ANGULAR MOMENTUM OPERATIONS L^2, S^2, AND J^2 IN J–J COUPLING. APPLICATION TO THE STUDY OF SOME RELATIVISTIC EFFECTS. **Bessis, N. (Univ., Lyon); Bessis, G.; Desclaux, J. P. J. Phys. (Paris), Colloq.; 31: No. 11-12, C.231-9(Nov-Dec 1970).**

From International symposium on the theory of atomic structure; Gif-sur-Yvette, France (8 Jul 1970). See CONF-700718.

Within the Slater determinant formalism, a straightforward procedure is given to calculate the simultaneous eigenfunctions of the angular momentum operators L^2, S^2, and J^2 in (j.j) coupling. The set of the eigenfunctions corresponding to any given configuration $(n_1\ l_1)^{x1}\ (n_2\ l_2)^{x2}$... is obtained by diagonalizing a square symmetric matrix. The matrix elements formulas are explicited. This method is well adapted for automatic computation. As an illustration, the (LSJ) wave functions in (j.j) coupling are used as in relativistic calculations for the open-shell case. (auth) (France)

58802 MANY-BODY THEORY OF AUTOIONIZATION. **Yaris, Robert; Boehm, Richard (Washington Univ., St. Louis). J. Chem. Phys.; 55: No. 4, 1802-10(15 Aug 1971).**

By regarding autoionization as the outgoing part of a resonant ion–electron scattering event, it is possible to employ a previously developed many-body theory of elastic and inelastic ion–electron scattering to develop a many-body theory of autoionization. This approach expresses the autoionization probability amplitudes in terms of the ion's one-particle Green's function and response function, which are determined self-consistently. (auth)

58803 MAGNETIC-DIPOLE TRANSITION OPERATOR WITH AN ACCURACY TO α^2 FOR ATOMS WITH ONE OR TWO ELECTRONS. Beigman, I. L.; Safronova, U. I. (Lebedev Inst. of Physics, Moscow. Inst. of Spectroscopy, Moscow). Zh. Eksp. Teor. Fiz.; 60: No. 6, 2045-50(Jun 1971). (In Russian).

The usual expansion of atomic functions into powers of $\alpha^2(\alpha = e^2/hc)$ is found to be insufficient for calculation of forbidden-transition probabilities. Terms of the order of α^2 in the expansion of the relativistic transition operator should also be taken into account. An expression for the magnetic-dipole transition operator in one- and two-electron systems is obtained. Probabilities for the single-photon transitions $2s^3S \rightarrow 1s^1S$ and $2s^1S \rightarrow 2s^3S$ are calculated on the basis of this expression for helium-like ions. A similar expansion has also been obtained for electric-dipole transitions. In this case additional terms $\sim\alpha^2$ remove the intercombination restriction for pure LS coupling. (auth)

58804 COMPOUND STATES IN ATOMS AND MOLECULES. **Herzenberg, A. (Univ. of Manchester, Eng.). pp 131-65 of Methods and Problems of Theoretical Physics. /Bowcock, J. E. (ed.). New York; American Elsevier Publishing Co., Inc. (1970)**

From Conference on methods and problems of theoretical physics; Birmingham, England (Jun 1967).

Adaptation of the Kapur–Peierls formalism is carried out, and a few examples of resonance reactions arising in the scattering of electrons from atoms and molecules are cited. An inverse reaction is described, in which an electron-unstable state is produced in a slow collision of an atom and a negative ion. A brief indication of some possible future developments is given. 38 references. (W.D.M.)

58805 SOLUTION OF THE DELTA-FUNCTION MODEL FOR HELIUM-LIKE IONS. **Rosenthal, Carey M. (Univ. of Wisconsin, Madison). J. Chem. Phys.; 55: No. 5, 2474-83 (1 Sep 1971).**

A one-dimensional Fredholm integral equation is derived for the ground-state solution of the delta-function model for two-electron helium-like ions. This equation is solved numerically; the perturbation series is developed through $E^{(20)}$ and compared with the solution of the integral equation. The series is further analyzed in terms of the singularity that determines its radius of convergence. (auth)

58806 STRUCTURE OF SYMMETRY PROPERTIES OF CORRELATION FUNCTIONS IN THE SINANOGLU NONCLOSED-SHELL MANY-ELECTRON THEORY. **Westhaus, Paul (Oklahoma State Univ., Stillwater). J. Chem. Phys.; 55: No. 5, 2507-13(1 Sep 1971).**

The general nonclosed-shell many-electron theory of Sinanoğlu is analyzed to show the structure of the correlation functions that arise. A particular representation of these functions as projections from the exact many-electron wave function is developed. The origin of the three distinct types of correlation effects—internal, semi-internal, and all external—present in open-shell states is discussed. The representation of the correlation functions as projections is employed to examine their transformation properties under the operations of the symmetry group of the Hamiltonian. (auth)

58807 FREQUENCY DISTRIBUTION OF RADIATION EMITTED FROM EXCITED ATOMIC SYSTEMS. **Hearn, Dwight D. (Univ. of Utah, Salt Lake City). Int. J. Quant. Chem.; 5: No. 5, 565-74(Sep 1971).**

General expressions for the time-dependent probability amplitudes of the quantum states of two arbitrary interacting atoms are calculated when one atom is initially in an excited p state and the other atom is in an s ground state. The lifetimes of the excited states and the line shape of the emitted radiation are obtained as functions of both the atomic separation and the energy difference between the excited states of the two atoms. The emission-line shape is shown to be doubly peaked and to agree with the line shape of the radiation scattered by a system of two interacting atoms. The expressions for the lifetimes of the excited states are found to be identical to those obtained for the radiation-scattering situation. (auth)

58808 FURTHER SIGNIFICANCE OF THE PARISER METHOD FOR EVALUATION OF THE ONE-CENTER ELECTRON REPULSION INTEGRAL. **Anno, Tosinobu; Sakai, Yoshiko (Kyushu Univ., Fukuoka). J. Chem. Phys.; 55: No. 6, 2827-31(15 Sep 1971).**

There is a difference between the nonempirical and the semiempirical value of the one-center electron repulsion integral, even if correct recognition is made of the atomic species for which the semiempirical value of the integral is determined with consideration of an electron-transfer reaction according to Pariser. This difference was analyzed for the integral that represents the average interaction of a pair of 2p electrons within an atom. It is shown that the main source of the difference is the failure of the usual nonempirical determination of the integral in considering properly the reorganization of the electrons occurring in the course of the electron-transfer reaction. The correlation energy is shown to have only minor contribution to this difference. (auth)

58809 VAN DER WAALS FORCES INCLUDING EXCHANGE IN THE SMALL OVERLAP REGION. **Boehm, Richard; Yaris, Robert (Washington Univ., St. Louis). J. Chem. Phys.; 55: No. 6, 2620-9(15 Sep 1971).**

A linear-response approach based on the many-body Green's function techniques of Martin and Schwinger is employed to obtain an intermediate-range theory of interatomic forces between ground-state atoms. Electron exchange is included to lowest order in a natural and physically transparent way. The result for the interaction energy is expressible in terms of local and nonlocal response functions associated with the individual atoms. Moreover, the long-range limit of this expression for the interaction energy is explicitly demonstrated to reduce to the familiar van der Waals dispersion interaction. Finally the extension of the linear-response approach to include exchange to the theory of nonadditive three-body interactions is briefly discussed. (auth)

58810 ERROR BOUNDS TO EXPECTATION VALUES. Mazziotti, Alexander (Johns Hopkins Univ., Baltimore. Columbia Univ., New York). J. Chem. Phys.; 55: No. 6, 2657-60 (15 Sep 1971).

Upper and lower bounds to a true expectation value, P, are given by $(E_{\mu L} - \tilde{E})/\mu \leq P \leq (\tilde{E} - E_{\lambda L})/\lambda$, where $\tilde{E}$ is the variationally minimized energy for the system of interest and $E_{\mu L}$, $E_{\lambda L}$ are lower bounds to the energies associated with reference Hamiltonians, $H_{\lambda}^{\mu} = H \pm {}_{\lambda}^{\mu}\hat{P}$, with $\lambda, \mu > 0$. These bounds are unique in that they are skewed about the approximate expectation value $\tilde{P}$, and because their application is not limited to positive definite operators. Approximate formulas, $dU^2\lambda/d\lambda$ (the derivative of variance with respect to parameter λ in H_{λ}) and $\langle\tilde{\psi} \mid \hat{P}(H-\tilde{E}) \mid \tilde{\psi}\rangle$ (where $\tilde{\psi}$ is an approximate wave function) are shown to give the correct sign of an expectation value error. (auth)

58811 APPLICATION OF RAYLEIGH–SCHROEDINGER PERTURBATION THEORY TO THE HYDROGEN ATOM. II. Gray, B. F. (Univ. of Leeds, Eng.). J. Chem. Phys.; 55: No. 6, 2848-52(15 Sep 1971).

Various unsuccessful attempts to treat the hydrogen-atom problem by perturbation theory, starting from a free particle as the unperturbed state, are examined. Calculations in closed form are presented, confirming the incorrect results but throwing light on the reasons for the failure, which occurs in spite of the fact that convergent power-series expansions in the perturbation parameter exist and are known explicitly. The failure is shown to be essentially due to nonuniform convergence at the point where the boundary conditions are applied, and furthermore this failure occurs for a wide class of potentials besides the Coulomb. Previous methods of avoiding this difficulty for the Coulomb potential are shown not to be of general validity. (auth)

58812 ANALYTICAL RESULT ABOUT CO-OPERATIVE SPONTANEOUS EMISSION. Bonifacio, R.; Gronchi, M. (Univ., Milan). Lett. Nuovo Cim.; 1: No. 26, 1105-8(26 Jun 1971).

The co-operative decay of N two-level atoms is discussed. If the atoms are initially all excited, the variance of the atomic energy increases as N^2 as the system approaches the superradiant state, i.e., that state in which N/2 atoms are in the ground state. A similar behavior is found for the radiated intensity. These results, previously determined from numerical calculations, are verified through an analytical proof. It is found that the relative variance σ/N is independent of the number of atoms; this large variance of the atomic energy during the superradiant pulse from the fully excited state is due to atom–atom correlation and is responsible both for the large deviation of the radiated intensity from the classical value and for the large fluctuation of this intensity. (R.W.R.)

58813 IMPROVED LAMB-SHIFT CALCULATION FOR ALL VALUES OF Z. Erickson, Glen W. (Univ. of California, Davis. Univ. of Surrey, Guildford, Eng.). Phys. Rev. Lett.; 27: No. 12, 780-3(20 Sep 1971).

A previous covariant evaluation of the Lamb shift for small atomic numbers Z is extended to be valid for large Z and agrees with independent numerical evaluations for Z near 80. The results improve the precision tests of quantum electrodynamics and could be used for one-electron atoms with any Z, x rays at large Z, and superheavy elements with $Z\alpha > 1$. A substantially new value (due to deuteron size) is found for the deuterium Lamb shift: 1059.27 ± 0.03 MHz. (auth)

58814 VARIATIONAL POTENTIALS AND LAGRANGIAN MULTIPLIERS IN PSEUDOPOTENTIAL THEORY. Schwarz, W. H. Eugen (Univ., Bonn). J. Chem. Phys.; 55: No. 7, 3607-8(1 Oct 1971).

Use of Lagrangian multipliers in solution of pseudo-Fock equations for closed-shell systems is discussed. It is concluded that—contrary to the Fock equations—use of the Lagrangian multipliers makes the situation worse rather than better and also complicates the numerical procedure. Introduction of the frozen-core approximation into pseudopotential theory is considered briefly. (A.G.W.)

58815 STATISTICAL ATOM MODEL BASED ON A LOCAL COULOMB APPROXIMATION. Ashby, Neil; Holzman, Melvyn A. (Univ. of Colorado, Boulder). pp 1-14 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

An improved "semistatistical" model capable of incorporating relativistic effects, and which utilizes more precise quantum-mechanical information about the electron density near the nucleus, was discussed by Ashby and Holzman (Phys. Rev., 1: 764 (1970)). Although the semistatistical model gives improved potentials and total energies, it does not exhibit electronic shell structure. This paper presents another model of the atom, intermediate in complexity between the semistatistical and Hartree Self-Consistent Field (SCF) models, which still permits rapid numerical calculation, in which the inner shell structure appears, and which also can be generalized to include relativistic effects. (L.M.T.)

58816 RELATIVISTIC RADIATIVE TRANSITIONS. Garstang, R. H. (Univ. of Colorado, Boulder). pp 153-67 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

Most calculations on the intensities of spectrum lines have been based on wave functions calculated from solutions of Schrödinger's equation. It was realized by Darwin (Proc. Roy. Soc., A118: 654 (1928)) that if wave functions were obtained from Dirac's relativistic equation the resulting spectroscopic line intensities would be different from the nonrelativistic theory. Darwin pointed out that for hydrogen the difference between the relativistic and nonrelativistic results would be very small, and that for practical purposes the intensity ratios in doublet spectra could be considered as having their usual values. In this article the work that has been done on calculation of relativistic transition probabilities for bound–bound transitions, primarily for hydrogen-like atoms, is surveyed. 37 references. (auth)

58817 CORRELATION OF THE SCREENING CONSTANTS FOR THE K LEVEL FOR ATOMS OF DIFFERENT Z. Gokhale, B. G.; Sahai, Vineet (Lucknow Univ., India). Indian J. Pure Appl. Physics.; 9: No. 3, 190-2(Mar 1971).

The value of Sommerfeld's screening constant σ_1 was calculated for the K level in a number of atoms, and it is shown that it agrees well with the single screening constant introduced by C. Mande and P. S. Damle [Indian J. Pure Appl. Phys., 3: 142, (1965)]. The slight disagreement for higher values of Z is attributed to the interpenetration of electronic shells. (auth)

58818 GROUND STATE ENERGY OF TWO-ELECTRON ATOMS WITH ARBITRARY NUCLEAR CHARGES $Z \leq 137$. Klimchitskaya, G. L.; Labzovskii, L. N. (Leningrad State Univ.). Zh. Eksp. Teor. Fiz.; 60: No. 6, 2019-25 (Jun 1971). (In Russian).

The ground-state energy of a two-electron atom with an arbitrary nuclear charge Z is calculated on the basis of quantum electrodynamics perturbation theory. The zero approximation is envisaged as two noninteracting Dirac electrons in the Coulomb field of the nucleus. Corrections of the first and second order with respect to Coulomb interaction between the electrons are calculated. A variational principle is proposed for second-order corrections. All corrections are calculated as functions of Z in the interval $1 \leq Z \leq 137$. (auth)

58819 FORMULA FOR RELATIVISTIC ATOMIC ENERGIES. Snyder, R. (Harvard Univ., Cambridge, Mass.). J. Phys., B (London); 4: No. 9, 1150-62(Sep 1971).

A formula is presented, which expresses the relativistic energy of many-electron atoms and ions as a simple function of the configuration quantum numbers and of the nuclear charge Z. For systems containing only 1s, 2s, and 2p electrons, the formula involves a four-by-four matrix $\sigma(i|j)$, whose sixteen elements are determined by thirteen theoretical Z-expansion coefficients and by three empirical parameters. The doublet splittings of $1s^22p\ ^2P$, $1s^22s^22p\ ^2P$, $1s^22p^5\ ^2P$, and $1s^22s^22p^5\ ^2P$ are treated, and the results are compared with spin–orbit results and with first-order Z-expansion treatments. The accuracy of the formula is found to be comparable with that of the most accurate spin–orbit calculations. The effects of configuration mixing on the $1s^22s^22p\ ^2P$ and $1s^22p^5\ ^2P$ splittings are discussed in an appendix. Relativistic corrections to the ionization potentials of $1s^22s$, $1s^22s^2$, $1s^22s^22p$, and $1s^22s^22p^6$ are calculated. (auth) (UK)

58820 DAMPING OF PLASMA OSCILLATIONS IN ATOMS. Sen, Abhijit. Knoxville, Tenn.; Univ. of Tennessee (1970). 113p. University Microfilms Order No. 71-17,774.
Thesis.

An attempt is made to resolve the question of the existence of collective (plasma) oscillations in atoms by calculating the damping. These oscillations have energies above the ionization potentials of the atoms and decay by the excitation of bound electrons to free states. Numerical estimates of the damping are obtained for a range of atomic numbers and frequencies, using two different models of the atom—the Jensen model and the Thomas–Fermi model. It is found that in some cases the decay time is much longer than the period of oscillation. It is concluded that weakly damped plasma oscillations can exist in atoms. (Diss. Abstr. Int., B)

58821 APPLICATION OF THE FACTORIZATION METHOD AND GROUP THEORY TO THE RELATIVISTIC TREATMENT OF HYDROGENIC RADIAL FUNCTIONS. **Crubellier, A.; Feneuille, S. (CNRS, Orsay, France). J. Phys. (Paris); 32: Nos. 5-6, 405-11(May 1971). (In French).**

It is shown that the relativistic expression for the radial functions of the bound states of a hydrogenic atom can be used in conjunction with the generalized solution of the Kepler problem if the factorization method and group theory [0(2,1)] are simultaneously introduced. In this way a certain number of simple results were obtained for the radial matrix elements of r^K and r^{-K}. These results are applied to the relativistic treatment of the Zeeman effect (Breit–Margenau correction) and to the hyperfine structure (Casimir corrections). (France)

Cosmic Radiation

58822 COUPLING FUNCTIONS APPLICABLE TO THE UNDERGROUND MESON TELESCOPES. **Ahluwalia, H. S.; Ericksen, J. H. (Univ. of New Mexico, Albuquerque). J. Geophys. Res.; 76: No. 28, 6613-27(1 Oct 1971).**

A new procedure is proposed for determining the effective primary threshold energy (E_0) applicable to an underground meson telescope located at a moderate depth. E_0 so derived is used in Dorman's procedure for calculating the coupling functions for the underground meson telescopes from coupling functions applicable to a sea-level meson telescope. In this manner the coupling functions are derived for the underground meson telescopes located at 40 and 60 mwe under rock below sea level. The practical usefulness of these functions is demonstrated for the study of the rigidity dependence of the mean solar diurnal variation for the period January 1, 1968, to June 30, 1969, and the Forbush decrease of July 13, 1961. It is concluded that the median primary energy of response of an underground meson telescope is much lower than has been believed. (auth)

58823 COMPARATIVE STUDY OF THE RIGIDITY DEPENDENCE OF FORBUSH DECREASES AND 11-YEAR VARIATION IN COSMIC-RAY INTENSITY. **Mathews, T.; Stoker, P. H.; Wilson, B. G. (Univ. of Calgary, Alberta, Can.). Planet. Space Sci.; 19: No. 8, 981-91(Aug 1971).**

Results of a comparative study of Forbush decreases and the 11-year variation observed at Calgary, Sulphur Mountain, and other neutron monitor stations during the current cycle of solar activity are presented. The 11-year variation since 1965 is well accounted for by a modulation function of the form $e^{-k(t)/P}$, the same as that found suitable for the previous solar cycle. No definite difference between modulation functions applicable to Forbush decreases and 11 year variation from a comparative analysis of data on daily average counting rates from different latitude stations was found. However, hourly data from Calgary and Sulphur Mountain do suggest a difference in modulation at low rigidities, the modulation tending to become rigidity-independent. (auth) (UK)

58824 SOLAR DIURNAL VARIATION OF COSMIC RAYS AT THE 1954 SOLAR MINIMUM. **Thomson, D. M. (Makerere Univ., Kampala, Uganda). Planet. Space Sci.; 19: No. 9, 1169-83(Sep 1971).**

A re-examination of cosmic-ray data at the 1954 solar minimum shows that the anomalous diurnal variation during July, August, and September 1954 was not a sidereal time effect but was associated with a streaming of cosmic rays in a direction perpendicular to the interplanetary-field lines and towards the Sun. The phenomenon is discussed in terms of the theory of diffusion and scattering of cosmic rays in the interplanetary medium. It is shown that the phenomenon could have been the result of an additional gradient in cosmic-ray density due to asymmetric modulation of cosmic rays north and south of the ecliptic plane. Assuming that the interplanetary field was predominantly directed towards the Sun the effect implied a shift of the effective minimum of cosmic-ray density by some 15° northwards from the ecliptic. It is surmised that this asymmetric modulation may have some connection with the asymmetry in solar activity at the 1964–1965 solar minimum. Reasons are given for supposing that such "reverse streaming" of cosmic rays is likely to occur only close to solar minima. (auth)

58825 PERIODIC VARIATIONS OF THE COSMIC RADIATION. II. THE SIDEREAL TIME PERIOD. **Messerschmidt, W. (Martin-Luther Univ., Halle, Ger.). Planet. Space Sci.; 19: No. 9, 1025-40(Sep 1971).**

An approach is made to an evidence of the sidereal time period of the cosmic radiation. The evaluation is based on measurements at 6 stations. In order to observe the properties of the sidereal time period for a long time, the data were classified into time intervals according to the different solar activity or they were summed up over eight to ten years. The analysis can only be carried out if some simplifying assumptions are made. The sidereal time period is supposed to be constant and the daily period should only show a seasonal modulation of the amplitude. For correcting the sidereal time period obtained, the method of Farley and Storey (1954) was applied. It uses one side band of the daily period —the anti-sidereal time period —to gain the genuine sidereal time period by removing the influence of the spurious sidereal time period. The monthly course of the daily period was reconstructed in three typical examples with the help of the established yearly means of the daily period, the sidereal time period and the anti-sidereal time period. The evidence of the sidereal time period is confirmed. Its amplitude amounts to 0.03 to 0.10%. In the southern hemisphere the maximum lies between 05 and 06 local sidereal time, and in the northern hemisphere between 20 and 21 LST, in good agreement with other authors. (auth)

58826 ABSOLUTE INTENSITIES OF COSMIC RAY MUONS ABOVE 3.48 AND 7.12 GeV/c. **Ayre, C. A. (Univ. of Durham, Eng.). J. Phys., A (London); 4: No. 5, L89-93(Sep 1971).**

The new Durham spectrograph MARS was used to determine absolute intensities of cosmic-ray muons in the near vertical direction with momenta above 3.48 and 7.12 GeV/c. The intensities are found to be close to those previously reported by Aurela and Wolfendale in 1967, the present intensities being higher by some (7.7 ± 1.3)% and (1.7 ± 1.4)%, at the respective momenta. Comparison is also made with the results of other recent measurements. (auth)

58827 COUPLING BETWEEN PRIMARY AND SECONDARY COSMIC-RAY MUON VARIATIONS AT HIGH ENERGIES. **Bedewi, F. El.; Goned, A. (Ein Shams Univ., Cairo). J. Phys., A (London); 4: No. 5, 660-4(Sep 1971).**

The muon sea-level integral multiplicity and the coefficients of coupling between primary and secondary muon variations were derived as functions of primary energy for various absorber thicknesses and zenith angles using the Cocconi–Koester–Perkins interaction model. The calculated multiplicities were found to agree at low energies with those derived from geomagnetic data and to be in general accordance with those obtained from nucleon cascade calculations at high energies. The calculated coupling coefficients were observed to depend weakly on zenith angle and to change with primary energy E as E^3 at low energies and as $E^{-2.2}$ for energies above 500 GeV. (auth)

58828 GROUPS OF PARALLEL PENETRATING PARTICLES AND THEIR POSSIBLE SOURCES. **Bibilashvili, M. F. (Inst. of Physics, Tbilisi, USSR). JETP Lett. (USSR) (Engl. Transl.); 13: No. 11, 457-9(5 Jun 1971).**

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 13: No. 11, 643-6(5 Jun 1971).

A spark calorimeter was used to describe groups of penetrating particles at depths on the order of several hundred kg/cm^2 when most of the particles forming these groups represent muons produced trivially in decays of pions or kaons in the atmosphere. The procedure involves assuming four regions arbitrarily called small bursts-small distances, large bursts-small distance, small bursts-large distances, and large bursts-large distances. The correlation between the spatial and energy characteristics in groups of two, three, or four particles was investigated using data on the angular distributions. The procedure shows that at least three processes are responsible for the production of groups of penetrating particles and that the characteristics obtained make it possible to estimate a parameter such as the X-hadron mass. (J.C.W.)

58829 X- AND γ-RAY ASTRONOMY AND THE TD-1, HEOS-B, AND COS-B SATELLITE MISSION. **Koch, L. (CEN de Saclay, Gif-sur-Yvette, France). Rech. Spatial.; 10: No. 3, 18-20(May 1971). (In French).**

The principal characteristics of equipment that will be aboard the TD-1, HEOS-B, and COS-B satellites are given: the x and γ detectors of the TD-1 satellite and the gamma-ray telescope operating in the 30-MeV to 2-GeV range from the COS-B satellite. (France)

58830 COSMIC ELECTRON ACCELERATION AND THE SPECTRUM OF METAGALACTIC X RAYS. **Dolginov, A. Z.; Gnedin, Yu. N. (Ioffe Inst. of Physics and Tech., Leningrad). Astrophys. Lett.; 9: No. 2, 91-4(Sep 1971).**

XUM

The power spectrum of cosmic relativistic electrons is explained as due to the acceleration and scattering of electrons in turbulent plasma with a frozen-in magnetic field. It is shown that the bends in the electron spectrum may be due not only to synchrotron or inverse Compton-effect losses but also to a change in the energy dependence of the acceleration rate. In this case the break in the spectrum is not restricted to unity. A possibility is discussed of explaining the bend in the metagalactic x-ray spectrum as a result of the bend in the electron spectrum. (auth)

58831 COSMIC GAMMA-RAY MEASUREMENTS IN THE RANGE 0.3 TO 3.7 MeV. Golenetskii, S. V.; Mazets, E. P.; Il'inskii, V. N.; (and others) (Ioffe Inst. of Physics and Tech., Leningrad). Astrophys. Lett.; 9: No. 2, 69-74(Sep 1971).

A study of the spectrum, latitude dependence, and time variations of the low-energy gamma-radiation intensity was carried out in the vicinity of the Earth on the Cosmos 135 and Cosmos 163 satellites by means of a multi-channel scintillation spectrometer. An upper limit for the flux of primary gamma-radiation was obtained in some energy intervals. The estimates obtained lie considerably below the values derived from measurements in the interplanetary space. Possible reasons for these discrepancies are discussed. (auth)

58832 EXTRATERRESTRIAL γ-RAY CONTRIBUTION BETWEEN 0.7 AND 4.5 MeV AT BALLOON ALTITUDE. Vedrenne, G.; Albernhe, F.; Martin, I.; Talon, R. (Centre d'Etude Spatiale des Rayonnements, Toulouse). Astron. Astrophys.; 15: No. 1, 50-4(Nov 1971).

The comparison of γ-ray results obtained through balloon flights at different latitudes enables an extraterrestrial contribution for γ rays to be detected in the 1 to 5 MeV energy range. The method for obtaining this γ-ray flux and its spectrum is described for a flight at low latitude (Guiana 10°N). The results seem to confirm the ERS 18 measurements in a similar energy range and to prove that the γ-ray cosmic component can be detected through balloon experiments. Other flights with larger detectors are planned to confirm these results and increase precision in the determination of this spectrum with, at the same time, an attempt to extend the spectrum to higher energy. (auth)

58833 RELATIVE ABUNDANCES OF THE ISOTOPES OF LIGHT NUCLEI (Li, Be, AND B) IN THE PRIMARY COSMIC RADIATION. Durgaprasad, N. (Tata Inst. of Fundamental Research, Bombay). Astrophys. Space Sci.; 12: No. 1, 243-9 (Jul 1971).

Studies were made to determine the relative abundances of the isotopes of lithium and boron in the primary cosmic rays in the low energy interval 120 to 400 MeV per nucleon recorded in the emulsion stack flown from Fort Churchill. Two independent measurements of mass, wherever possible, were made on each track by the range vs ionization method. The results obtained on nine stopping boron nuclei and two lithium nuclei are presented. (auth)

58834 RATIO OF PIONS TO PROTONS AND RATIO OF NEUTRAL-TO-CHARGED INTERACTING PARTICLES AT MOUNTAIN ALTITUDE OF 800 gm/cm^2. Lal, S.; Raghavan, R.; Rangaswamy, T. N.; Sreekantan, V.; Subramanian, A. (Tata Inst. of Fundamental Research, Bombay). Proc. Indian Acad. Sci., Sect. A; 73: No. 5, 213-22(May 1971).

Using a combined set-up of a multiplate cloud chamber, an air Cherenkov counter, and a total absorption spectrometer, the ratio of pions to protons not associated with large air showers was determined to be 0.50 ± 0.07 in the energy region 20 to 40 GeV at an altitude of 800 gm/cm^2. In the same energy region the ratio of neutral to charged particles was found to be 0.66 ± 0.07. From the ratio of neutrons to protons deduced from these measurements (i.e., 0.99 ± 11), it is concluded that most of the charge excess of nuclear-active particles of energies >20 GeV at mountain altitudes and sea level is due to pions. (auth)

58835 INVESTIGATION OF γ RADIATION BY THE ARTIFICIAL EARTH SATELLITE COSMOS-135. Konstantinov, B. P.; Golenetskii, S. V.; Mazets, E. P.; (and others). Cosmic Res. (USSR) (Engl. Transl.); 8: No. 6, 842-8(Nov-Dec 1970).

Translated from Kosm. Issled.; 8: No. 6, 923-30(Nov-Dec 1970).

The satellite Cosmos-135 conducted measurements of the space and time distributions of the intensity and spectral composition of γ radiation in the 0.3 to 2.7-MeV energy range using a multichannel scintillation γ spectrometer. A study was made of the accompanying measurements of the background effects which are caused by the secondary radiation which develops in the materials of the satellite and the detector itself due to the action of cosmic rays and captured radiation. The dependences of the magnitudes of the 0.4- to 2.5-MeV γ-radiation flux, the annihilation 0.511-MeV γ-radiation flux, and the flux of charged particles on the geomagnetic threshold hardness were obtained. The flux of γ quanta of extra-atmospheric origin in the indicated energy range was determined and was found to be about 0.35 ± 0.15 cm$^{-2}\cdot$sec^{-1}. (auth)

58836 INVESTIGATION OF VARIATIONS OF ANNIHILATION γ RADIATION BY THE ARTIFICIAL EARTH SATELLITE COSMOS-135 IN CONNECTION WITH THE POSSIBLE ANTIMATTER NATURE OF METEOR STREAMS. Konstantinov, B. P.; Golenetskii, S. V.; Mazets, E. P.; (and others). Cosmic Res. (USSR) (Engl. Trans.); 8: No. 6, 849-55(Nov-Dec 1970).

Translated from Kosm. Issled.; 8: No. 6, 931-8(Nov-Dec 1970).

The time variations of the intensity and spectral composition of γ radiation in near space were investigated in the 0.3- to 2.7-MeV energy range. The investigations were carried out during the epoch of the Geminide, Urside, and Quadrantide meteor streams during the winter of 1966–1967 in connection with the previously stated hypothesis of the possible antimatter nature of comets and meteor streams. The data obtained indicate that periods of considerable increase in the intensity of annihilation radiation having an energy of 0.511 MeV are observed. The effect amounts to ~50%. It does not involve the γ-radiation intensities in the remaining ranges of the spectrum investigated nor the intensity of charged particles. The increased intensity of the 0.511-MeV line was observed during the Geminide and Urside meteor streams. Evidently, no connection can be traced between the observed effect and the solar or geomagnetic activity. On the assumption that the discussed hypothesis is valid, the magnitude of the effect can be explained by an amount of antimatter ~20 mg introduced into the Earth's atmosphere during 1 day. (auth)

58837 SUPRATHERMAL PROTON BREMSSTRAHLUNG BY THE WEIZSAECKER–WILLIAMS METHOD. Jones, Frank C. (Goddard Space Flight Center, Greenbelt, Md.). Astrophys. J.; 169: No. 3, 503-6(1 Nov 1971).

The Weizsäcker–Williams method for calculating the bremsstrahlung cross section utilizes the rest frame of the electron as the natural frame in which to carry out the calculation in terms of Compton scattering the virtual photons of the proton electromagnetic field. Since suprathermal proton bremsstrahlung is a process in which the electron is initially at rest and the proton is moving, the Weizsäcker–Williams method is obviously the most natural one to use in this case. In this paper the cross section for suprathermal proton bremsstrahlung is calculated by means of this method, and the results are shown to differ considerably from those of a previous paper in which the conventional and much more difficult method was used. In particular it is concluded that the the suprathermal proton bremsstahlung process cannot explain the 2 to 6-MeV γ rays reported by Vette et al. (auth)

58838 (N–71–26273) ELECTRIC SPACE POTENTIAL IN A CESIUM THERMIONIC DIODE. Shimada, K.; Cannon, W. (Jet Propulsion Lab., Pasadena, Calif.). 31 Mar 1971. Contract NAS7-100. 19p. (NASA-CR-118519; JPL-TM-33-480). NTIS.

To investigate cesium plasma parameters required for a minimum plasma-loss operation of thermionic converters, a metal–ceramic device equipped with a movable Langmuir probe was constructed. The probe characteristics were examined for four different modes of cesium discharge including: (1) extinguished mode, (2) anode glow mode, (3) ball-of-fire mode, and (4) plasma mode to determine the space potentials and the electron energies in the plasma. The process of cesium ionization that is influenced strongly by the electric potential gradient is being studied to yield a minimum plasma-loss operation. (auth) (STAR)

58839 (TEE–4125–5) THERMIONIC PERFORMANCE OF CVD TUNGSTEN EMITTERS WITH NIOBIUM AND MOLYBDENUM COLLECTORS. Lieb, D.; Rufeh, F. (Thermo Electron Corp., Waltham, Mass.). May 1971. Contract AT(30-1)-4125. 78p. (TE–4137-134-71). Dep. NTIS.

Two chloride vapor-deposited W emitters were installed in variable spacing converters with Nb and Mo collectors. Thermionic performance data were collected in the form of current density–output voltage curves with cesium families and cesium optimized envelopes for various spacings and temperatures. The performance was compared with that of other converters having ⟨110⟩ and ⟨100⟩ W emitters. The effects of rebuilding one

XUM

converter and of collector temperature on performance were studied. (D.L.C.)

58840 INDUKTSIONNYE MAGNITOGODRODINAMICHESKIE MASHINY S ZHIDKOMETALLICHESKIM RABOCHIM TELOM. (Magnetohydrodynamic Induction Machines with Liquid-Metal Working Fluid). Vol'bek, A. I. Leningrad; Energiya Leningradskoe Otdelenne (1970). 272p.

The principles of operation and the construction of various types of inductive magnetohydrodynamic machines with a working fluid of liquid metal are examined. Attention is focused on liquid metal transport and the generation of electric power with a variety of coil windings for a single and multiphase operation. (K.S.W.)

58841 MHD POWER PLANT USING A LIQUID METAL EMULSION WITH GAS TURBINES ASSOCIATED WITH A HIGH TEMPERATURE GAS REACTOR. Bidard, Rene; Sterlini, Jacques (Compagnie Electro-Mecanique, Le Bourget, France). Bull. Inform. A.T.E.N. (Ass. Tech. Energ. Nucl.); No. 88, 29-38 (Mar 1971). (In French).

The problem of coupling an emulsion MHD generator with an HTR and the various solutions obtained from a basic family of perfect cycles are examined. The energy per mass unit available in these various cycles depends on the compression ratio chosen. It is enhanced by circulating in the reactor a gas coolant with a flow rate greater than that of the thermodynamic gas and by inserting a heat exchanger between the reactor and the generator. The case of an emulsion heat exchanger is envisaged and a theoretical calculation is given. The use of two gas turbines coupled in parallel is shown to yield a very attractive cycle. For a reactor working at 1500°K, a thermal efficiency in excess of 53% can be reached provided that the generator has an internal efficiency of 0.8 and the highest temperature before the gas turbine is not greater than 1,100°K (827°C). This efficiency is comparable with that announced by the authors (IAEA Colloquium, Salzburg, July 4 to 8, 1966 (SM-74/108)) in the case of the coupling with a sodium-cooled reactor. (auth)

58842 ELECTROHYDROMAGNETIC INSTABILITY OF SUPERPOSED FLUIDS. Bhowmik, G.; Talwar, S. P. (Univ. of Delhi). Appl. Sci. Res. (The Hague); 24: No. 2-3, 213-25 (Jun 1971).

The problem of stability of superposed viscous liquids subject simultaneously to electric and magnetic fields is investigated using the normal mode analysis. A configuration of an electrically conducting liquid topped by a dielectric liquid is envisaged in a downward gravity field. The electric field is assumed along the gravity field, while the magnetic field is taken to be either along or normal to the electric field. Criteria of instability are derived in both cases. It is found that a vertical electric field has a destabilizing influence and renders an otherwise stable configuration (bottom heavy arrangement) unstable for small wavelengths, while the effect of the magnetic field is stabilizing. (auth)

58843 TWO-DIMENSIONAL MAGNETOHYDRODYNAMIC CHANNEL FLOW IN A NONUNIFORM MAGNETIC FIELD. Urashima, Shin-o (Osaka Univ.). J. Phys. Soc. Jap.; 31: No. 4, 1249-58(Oct 1971).

A circular magnetic field is applied to the channel. The fluid is inviscid and thermally nonconductive. The electrical conductivity of the fluid is assumed to be small so that the distortion of the magnetic field is neglected. The basic equations are linearized and the solution is obtained by the method of Fourier transforms. The solutions consist of two parts, including three parameters: the Mach number, the interaction parameters, and the interval between the walls. One part comes from the interaction between the fluid and the magnetic field. The other is the interaction between the fluid and walls. The flow accelerates in the channel for the subsonic case. This fact indicates that the effect of the Joule heating overcomes the Lorentz force in the case of channel flow across the nonuniform magnetic field. (auth)

58844 CURRENT AND POTENTIAL DISTRIBUTIONS IN NONEQUILIBRIUM MHD PLASMAS AT HIGH MAGNETIC FIELD STRENGTHS. Lengyel, Lajos L. (Max-Planck-Institut fuer Plasmaphysik, Garching, Ger.). AIAA (Amer. Inst. Aeronaut. Astronaut.) J.; 9: No. 10, 1957-62(Oct 1971).

The method of characteristics is applied to steady-state two-dimensional current and potential distributions in loss-free nonequilibrium MHD plasmas. The existence conditions of real characteristics are analyzed; the characteristic directions are defined and the corresponding compatibility relations are found. In an approximation corresponding to low ionization degree and moderate electron temperature elevation, analytic solutions are obtained for two particular cases: neutral collision and Coulomb-collision-dominated plasmas. The two families of characteristics are shown to coincide (neutral collisions) or nearly coincide (Coulomb collisions) with current streamlines and electric field lines. At magnetic field strengths above a critical value the discharge becomes striated even in ideal perturbation-free plasmas. The current flowing from electrode to electrode contracts to filaments of elevated current density. The solution indicates the existence of eddy currents in the system which consume a part of the applied (or induced) voltage, thus impairing the attainable electrical efficiencies. (auth)

58845 OPTIMAL DISTRIBUTION OF A TENSOR OF SPECIFIC RESISTANCE OF A WORKING SUBSTANCE IN A MAGNETOHYDRODYNAMIC DUCT (CASE OF NONLOCAL VARIATIONS). Lur'e, K. A. Prikl. Mat. Mekh.; 35: No. 3, 512-31(May-Jun 1971). (In Russian).

Current maximization in the outer loop of a duct was studied by means of selecting a tensor with a given specific resistance of the working substance. In the statement of the problem a plane duct is considered, the walls of which are a dielectric throughout. In a second variant, the essential conditions of Jacob are treated mathematically, and last, in the case of the "short circuit," the duct is assumed to be bounded by horizontal electrodes and vertical insulators. The possibility of a satisfactory approximation to an optimum current value is discussed in the case of horizontal insulating partitions inserted in the duct. (K.S.W.)

58846 NEARLY SYMMETRIC KINEMATIC AND HYDROMAGNETIC DYNAMOS. Soward, A. M. (New York Univ., N. Y.). J. Math. Phys. (N. Y.); 12: No. 9, 1900-6(Sep 1971).

Certain aspects of the hydromagnetic and kinematic dynamo theory related to the earth's magnetic field are considered. Previous work on the hydromagnetic dynamo is extended in two respects. First, the most general form of the prescribed body force which is consistent with the model is considered. Secondly, the mean quantity $\langle S_\phi \rangle$ is determined up to order $R^{-\frac{1}{2}}$, where R is the magnetic Reynolds number. It is shown that the remarkable effective variables first introduced previously are relevant in the hydromagnetic dynamo in the second approximation. It is also shown by considering a related problem concerning the heat conduction equation that effective variables are unlikely to have any relevance in the kinematic dynamo theory in the third approximation. (auth)

58847 PLANE NONSTATIONARY MAGNETOHYDRODYNAMIC BOUNDARY LAYER. Pop, Ioan. Stud. Univ. Babes-Bolyai, Ser. Math.-Mech.; 16: No. 1, 87-93(1971). (In French).

The effect of a magnetic field, changing in space and time, is studied at a break in the plane boundary layer from a body that suddenly begins to move from rest. The method of "similar" solution is employed, i.e., the conversion of the boundary-layer equations into ordinary differential equations, the solution to which is produced in closed form. It is noted in the case of a circular cylinder that, as the magnetic field increases, the break in the boundary layer occurs later. (tr-auth)

58848 STABILITY OF COMPRESSION SHOCK IN MAGNETOGASDYNAMIC FLOWS IN CHANNELS. Slobodkina, F. A. Zh. Prikl. Mekh. Tekh. Fiz.; No. 1, 16-23(Jan-Feb 1970). (In Russian).

The effect of the form of the boundary conditions in the exit cross section of the channel on stabilization of compression shocks in gasdynamic and magnetogasdynamic flows at small magnetic Reynolds numbers is demonstrated. Criteria for stabilization of shocks located near the channel exit are obtained. The influence of electromagnetic effects was studied. (tr-auth)

58849 ELECTRODYNAMICS OF TURBULENT MOVING ELECTRICALLY CONDUCTING MEDIA WITH CONSIDERATION OF THE HALL EFFECT. Helmis, G. (Deutsche Akademie der Wissenschaften, Berlin). Cosmic Electrodyn.; 2: No. 2, 197-210(Jul 1971). (In German).

The mean value of v × B in a turbulently moving electrically conducting medium is calculated, taking into account the influence of the Hall effect. The turbulence is assumed to be homogeneous, isotopic, but not symmetric with respect to reflection. General expressions are developed for small turbulence velocities; exactly valid formulas are derived for special correlation tensors and any value of conductivity and the Hall parameter. It follows from the calculations that the mean value of v × B decreases with increasing Hall parameter, but the influence of the Hall effect is reduced by increasing electrical conductivity. (tr-auth)

58850 DISTRIBUTION DISCONTINUITIES OF ELECTRIC CURRENTS AND FIELDS IN FLOWS WITH THIN LAYERS OF HIGHLY CONDUCTING GAS. Kholshchevnikova, E. K. Zh. Prikl. Mekh. Tekh. Fiz.; No. 1, 39-43(Jan-Feb 1970). (In Russian).

On the basis of solutions obtained by the Fourier method, the effect of a highly conducting thin gas layer on Joule dissipation and current distribution in the end zone of a plane MHD duct with nonconducting walls is analyzed. It is assumed that the MHD interaction parameter, magnetic Reynolds number, and Hall parameter are small. It was found that in some cases it is possible to replace the highly conducting thin layer by surface dislocations and still effect completely the definite relations between electric magnitudes. The presence of such a layer leads to an increase of Joule dissipation and to a decrease of the lines of current. (tr-auth)

58851 STABILITY OF AN EXPLICIT SCHEME FOR THE JOINT SOLUTION OF THE ENERGY EQUATION AND THE RADIATION TRANSFER EQUATION. Chetverushkin, B. N. (Inst. for Applied Mathematics, Moscow). Chislennye Metody Mekh. Sploshnoi Sredy; 1: No. 1, 95-9(1970). (In Russian).

If there is no equilibrium between the matter and the radiation, the radiative gasdynamic problem is solved by means of the transfer equation. The flux obtained depends on the temperature in all points of the space. It was considered simpler to solve simultaneously the energy equation and the radiation transfer equation, determining the flux on the basis of data from the preceding time step. The stability of such an explicit scheme was investigated, transposing the results to a generalized case by linearization. The thus obtained condition agreed with the stability condition of an explicit scheme of the nonstationary thermal-conductivity equation. (TTT)

58852 (LA-tr-71-69) SOLAR WIND PARAMETER VARIATION, MAGNETIC ACTIVITY, AND ELECTRONS OF THE TAIL OF THE MAGNETOSPHERE AND THE RADIATION ZONE. Ivanov, K. G.; Mikerina, N. V. (Akademiya Nauk SSSR, Moscow. Institut Zemnogo Magnetizma, Ionosfery i Rasprostraneniya Radiovoln). Translated by Helen Dahlby (Los Alamos Scientific Lab., N. Mex.), from Russian Preprint No. 2. 15p. Dep. NTIS.

Data from previous works are used to analyze the solar-wind parameter variation and magnetic activity. A high correlation is expected from the magnetic-activity variations with the variations of the southern component, F_S, of the magnetic field or the eastern component, E_E, of the electric field of the solar wind. The variations of the magnetic activity are fairly closely related to the electron variations in the magnetotail, and it can then be assumed that a relation exists between the solar-wind parameters and the characteristics of the electron fluxes of the magnetosphere. An attempt was made to find a relationship from the data on electrons during the periods of Sept. 26, 1966 and July 5–12, 1966 for the magnetospheric storms for which there are observations on the solar-wind correlation with the F_S, E_E, K_p, and the magnetic flux, ϕ. 34 references. (J.C.W.)

58853 (N-71-27792) RISK OF SOLAR PROTON EVENTS TO SPACE MISSIONS. Burrell, M. O. (National Aeronautics and Space Administration, Huntsville, Ala. George C. Marshall Space Flight Center). Jun 1971. 84p. (NASA-TN-D-6379). NTIS.

The total dose from solar protons was tabulated in rads-tissue for weekly time intervals, and the number of weeks that gave a dose above 25 rads behind 10 g/sq m of aluminum for the active six years of the 19th cycle were called dangerous or large-event weeks. Only three such event weeks were found during the past 20 years. Even though the possibility of smaller events was examined, it was found that for any reasonably high confidence level (95%), the smaller events could be ignored. Consequently, the total particle flux for the 19th cycle was divided by a factor of three and a single large event week was determined. The Poisson distribution was the most logical choice for predicting the probability of an event occurring. This conclusion and the methods of using this probability model are examined. The confidence one could use in employing the Poisson process and specifically arriving at confidence levels for the experimental or observed value of the mean of the Poisson distribution function is defined. Several examples are given for different mission lengths, and comparisons to other results are made. (STAR)

58854 LOCATING THE MAGNETOSPHERIC RING CURRENT. Thorne, R. M.; Kennel, C. F. (Univ. of California, Los Angeles). Comments Astrophys. Space Phys.; 3: No. 4, 115-20(Jul-Aug 1971).

Ground-based observations of the geomagnetic field give no clue about the location of the ring current. It is pointed out that 10- to 100-keV protons, which dominate ring-current energetics, have two preferred regions of cyclotron instability and consequently, loss, which serve as stable trapping boundaries for ring-current protons. The pertinent electromagnetic ion cyclotron instability therefore limits the ring current location, and, using the empirical notion that within the stable region the energy density does not exceed the geomagnetic energy density, also the ring-current energy density, and therefore, the main-phase depression. (W.D.M.)

58855 INTERACTION BETWEEN INTERSTELLAR HELIUM AND THE SOLAR WIND. Holzer, T. E.; Axford, W. I. (Univ. of California, San Diego, La Jolla). J. Geophys. Res.; 76: No. 28, 6965-70(1 Oct 1971).

Vela-3A satellite observations suggest that the solar-wind He^+ abundance is occasionally much larger than would be expected if the solar-wind ionization state were determined in the solar corona at temperatures of the order of 10^6°K. A further study is made of the suggestion that photoionization of interstellar helium atoms could produce a sufficiently large number of He^+ ions in the solar wind to explain the Vela-3A data. It is shown that the photoionization of interstellar He atoms can lead to solar-wind He^+ ions with large thermal speeds and nonradial flow velocities, unlike those of other solar-wind ions, and the result is not inconsistent with the satellite data. A helium number density of the order of 10^{-2} cm^{-3} in the interstellar gas appears to be sufficient to produce the observed solar-wind He^+ fluxes. (J.C.W.)

58856 RELATIONSHIP OF INTERPLANETARY PARAMETERS AND OCCURRENCE OF MAGNETOSPHERIC SUBSTORMS. Foster, J. C. (Univ. of Maryland, College Park); Fairfield, D. H.; Ogilvie, K. W.; Rosenberg, T. J. J. Geophys. Res.; 76: No. 28, 6971-5(1 Oct 1971).

Features from 54 substorms were averaged to use in the study of the relationship between magnetic-field parameters, plasma parameters, and magnetospheric substorms on a time scale of approximately 3 min. A southward component of the interplanetary field in producing geomagnetic disturbances was stressed in the studied. It is concluded from the behavior of substorms studied that the solar-wind proton data, and the interplanetary magnetic-field magnitude and equatorial-plane components, do not exhibit any significant morphological features that can be related to geomagnetic-substorm development. The data examined strongly reaffirm the relationship between a southward interplanetary magnetic-field component and the occurrence of substorms and indicate that this relationship is the dominant effect immediately preceding and during substorms. (J.C.W.)

58857 ROCKET MEASUREMENTS OF MAGNETIC FIELDS ASSOCIATED WITH VISUAL AURORAE. Burrows, K.; Stolarik, J. D.; Heppner, J. P. (Goddard Space Flight Center, Greenbelt, Md.). Planet. Space Sci.; 19: No. 8, 877-90(Aug 1971).

The results of two Nike–Tomahawk flights of rubidium vapour magnetometers from Fort Churchill, Canada are presented and discussed, together with relevant ground data. These flights confirm that the electrojet currents tend to concentrate within the boundaries of the visual auroral forms when they are present. As the most pronounced field changes occurred in the 95- to 130-km range of altitudes, they also support the concept that the auroral electrojet currents are predominantly Hall currents. (auth) (UK)

58858 CORRELATION BETWEEN PULSATING AURORA AND COSMIC RADIO NOISE ABSORPTION. Brekke, A. (Auroral Observatory, Tromsoe, Norway). Planet. Space Sci.; 19: No. 8, 891-6(Aug 1971).

A statistical analysis of the correlation between auroral pulsations and auroral absorption at Tromsø was performed for the years 1964 to 68. The two phenomena seem to be completely independent except for perhaps some short periods around midnight and in the late morning hours. A timeshift for the daily maximum of pulsating aurora with the solar activity is seen. (auth) (UK)

58859 CONSTANT-PRESSURE, TAIL-LIKE EXTRUSION OF PLASMA INTO THE CONFINED MAGNETIC FIELD OF A LINE DIPOLE. Hewson-Browne, R. C.; Kendall, P. C. (Univ. of

Sheffield, Eng.). Planet. Space Sci.; 19: No. 8, 869-76(Aug 1971).

A magnetic line-dipole field may be confined within an otherwise empty cavity by an infinitely conducting plasma at constant pressure, free of magnetic field. The problem has applications in the theory of the magnetosphere. The possible configurations are more numerous than has been supposed hitherto. It is shown, in particular, that a cavity is possible with an infinitely long tail-like extrusion into it of plasma at constant pressure. The successful formation of the tail is due to the uniform magnetic pressure outside the tail. The electric currents in the tail distort the otherwise symmetrical cavity, moving the magnetic cusps a little way round its surface onto the side opposite from the tail. The effects of the tail currents are limited, though, by the condition that the tail remains all in one piece. The features of this model which are relevant to the topology of the Earth's magnetosphere are discussed. The problem is solved by the use of conformal transformation in the complex plane. The method is applicable to models in which the plasma sheet is inclined at an arbitrary angle to the axis of the dipole. (auth) (UK)

58860 COMPARISON OF GEOMAGNETIC STORMS AND TROUGH DEVELOPMENT AT SOLAR-ACTIVITY MAXIMUM AND MINIMUM. **Woodbridge, David D. (Florida Inst. of Tech., Melbourne). Planet. Space Sci.; 19: No. 8, 821-6(Aug 1971).**

Geomagnetic storms have long been found to be related to solar storms. However, the effects of solar activity within the lower atmosphere have been postulated but not as yet confirmed. A positive correlation was found between trough development at 300 mb and geomagnetic storms during the 1956 to 57 solar-activity maxima in a study performed at the High Altitude Observatory of the University of Colorado. Similar studies performed at the Army Ballistic Missile Agency and at Florida Institute of Technology also showed positive correlations between geomagnetic storms and subsequent trough development. A comparison of the results of these investigations into a possible solar-weather effect are presented. (auth) (UK)

58861 COMMENT ON TRAJECTORY CALCULATIONS IN THE WILLIAMS AND MEAD GEOMAGNETIC-FIELD MODEL. **Morfill, G. E. (Imperial Coll. of Science and Tech., London). Planet. Space Sci.; 19: No. 8, 1016-18(Aug 1971).**

To study the impact zones associated with the entry of solar protons to the polar ice cap, it is necessary to integrate solar-proton trajectories in a high degree simulation of the geomagnetic field. For this, an accurate field representation out to ~20 Earth radii is required. Reasons for accepting the Williams and Mead field model (Mead, 1964; Williams and Mead, 1965) are given, and limitations of previous work using this model are discussed. The integration of particle trajectories was performed using a modified McCracken (1962) program. The geomagnetic field was described using a 6-term expansion (Finch and Leaten 1957) of the internal field and the Williams and Mead external field due to currents in the magnetopause and tail. The difference between asymptotic approach directions for this 6-term expansion is shown, with trajectories terminated at the magnetopause or at 25 Earth radii along the tail. Good agreement is found for particles crossing the magnetopause on the day side, as the 2-term expansion still holds here, but when going down the tail results may be 50° longitude different. Calculation of the pitch angle for the tail regions allows important conclusions to be reached. (UK)

58862 AMBIPOLAR DIFFUSION ALONG MAGNETIC FIELD LINES IN PRESENCE OF AN ELECTRIC CURRENT. **Scholer, M.; Haerendel, G. (Max-Planck-Institut fuer Physik und Astrophysik, Garching, Ger.). Planet. Space Sci.; 19: No. 8, 915-27 (Aug 1971).**

The one-dimensional ambipolar diffusion parallel to the magnetic field is treated for the case of a plasma cloud imbedded in a weakly ionized gas with a homogeneous magnetic field. Cloud and background ions are distinguished. A constant electric current is allowed to flow from infinity through the cloud. The resulting coupled diffusion equations for cloud and background ions are solved numerically. The initial phase is characterized by distortions of the density distributions of the ions owing to electric polarization fields which are the more pronounced the higher the contribution from the test ions. The peak of the test-ion distribution will finally move in the direction of the electric current. Situations in the F region of the ionosphere where these effects become appreciable are likely to be affected by plasma turbulence and anomalous resistivity. (auth) (UK)

58863 TIME LAGS IN THE AURORAL-ZONE IONOSPHERE. **Reid, J. S.; Phillips, J. (Univ. of Tasmania, Hobart). Planet. Space Sci.; 19: No. 8, 959-69(Aug 1971).**

Fast-response riometers were operated at Macquarie Island (invariant latitude 64°S) in conjunction with balloon-borne x ray scintillators, a λ4278-Å photometer, and a loop for detecting micropulsations. The pulsations in cosmic-noise absorption (CNA) observed with the riometers were found to lag behind pulsations in bremsstrahlung x rays, auroral luminosity, and micropulsations occurring at the same time. These phase lags and the time asymmetry characteristic of CNA pulsations are shown to be consistent with the ionospheric rate equation. (auth) (UK)

58864 THERMOSPHERIC WINDS INDUCED BY AURORAL-ELECTROJET HEATING. **Cole, K. D. (La Troba Univ., Bundoora, Australia). Planet. Space Sci.; 19: No. 8, 1010-12 (Aug 1971).**

It is argued that joule dissipation of magnetospheric electric fields can cause significant winds in the low E region which are part of convection cells, with air rising over auroral electrojets and flowing away (towards) the jets in the upper (lower) thermosphere. Concomitant effects are the meridional transport of a net eastward momentum of the thermosphere acquired by the E × B drift at high altitude over the jets, and the overturning of the thermosphere and mixing of its neutral constituents (this mixing being assisted by spatially irregular joule heating). (auth) (UK)

58865 ROYAL ASTRONOMICAL SOCIETY MEETING ON STORM EFFECTS IN THE IONOSPHERE AND MAGNETOSPHERE, NOV. 20th 1970. **Quart J. Roy. Astron. Soc.; 12: No. 2, 169-79(Jun 1971).**

Brief summaries are given on the following topics: ionospheric storms; correlation between air density and magnetic disturbance deduced from changes in satellite spin rate; vlf radiowave observations of ionospheric disturbances during the period Mar. 4–18, 1970; storm increases of midlatitude F-layer electron concentration explained by modification of neutral air winds; storm effects on topside ionosphere temperatures and in composition; principal zones of elf/vlf emission; problems of interpretation of equatorial magnetic daily variations on disturbed days; storm effects on solar protons; rocket observations of precipitating charged particles above South Uist, Outer Hebrides, during the magnetic storm of April 21–22, 1970; variation of geomagnetic micropulsation periods with latitude and the plasmapause; and morphology of storms. (UK)

58866 VARIATIONS IN THE HIGH-LATITUDE PROTON TRAPPING BOUNDARY ASSOCIATED WITH POLAR MAGNETIC SUBSTORMS. **Lindalen, H. R.; Soeraas, F.; Aarsnes, K.; Amundsen, R. (Univ. of Bergen). Planet. Space Sci.; 19: No. 9, 1041-8(Sep 1971).**

Protons in the energy range (100 to 200) keV in the noon to midnight meridian plane are studied from data obtained by the ESRO-IA satellite. It is observed that during quiet geomagnetic conditions there is a single zone of precipitating protons located at an invariant latitude of 67° on the nightside and two zones located at invariant latitudes of 70 and 77° on the dayside. Closely correlated with the polar magnetic substorm, the proton-trapping boundary moves poleward, the two zones of proton precipitation on the dayside merge into one zone, and the energy input into the atmosphere increases. Preceding the poleward movement of the trapping boundary, there is an intensity increase in the already existing proton precipitation on the nightside. (auth)

58867 DYNAMICAL BEHAVIOR OF THERMAL PROTONS IN THE MIDLATITUDE IONOSPHERE AND MAGNETOSPHERE. **Banks, P. M.; Nagy, A. F.; Axford, W. I. (Univ. of California, San Diego, La Jolla). Planet. Space Sci.; 19: No. 9, 1053-67 (Sep 1971).**

Satellite and other observations have shown that H^+ densities in the midlatitude topside ionosphere are greatly reduced during magnetic storms when the plasmapause and magnetic-field convection move to relatively low L values. In the recovery phase of the magnetic storm the convection region moves to higher L values and replenishment of H^+ in the empty magnetospheric field tubes begins. The upwards flow of H^+, which arises from O^+–H charge exchange, is initially supersonic. However, as the field tubes fill with plasma, a shock front moves downwards toward the ionosphere, eventually converting the upwards flow to subsonic speeds. The duration of this supersonic recovery depends strongly on the volume of the field tube; for example calculations indicate that for L = 5 the time is approximately 22 hours. The subsonic flow continues until diffusive equilibrium is reached or a new magnetic storm begins. Calculations of the density and flux profiles expected during the subsonic phase of the recovery show that diffusive equilibrium is still not reached after an elapsed time of

XUM

10 days and correspondingly there is still a net loss of plasma from the ionosphere to the magnetosphere at that time. This slow recovery of the H^+ density and flux patterns, following magnetic storms, indicates that the midlatitude topside ionosphere may be in a continual dynamic state if the storms occur sufficiently often. (auth)

58868 MONTE CARLO ANALYSIS OF THE PASSAGE OF AURORAL X RAYS THROUGH THE ATMOSPHERE. **Pilkington, G. R.; Anger, C. D. (Univ. of Calgary, Alberta). Planet. Space Sci.; 19: No. 9, 1069-85(Sep 1971).**

The deep penetration of auroral x rays into the atmosphere is examined by means of a Monte Carlo calculation in order to determine the effects of atmospheric scattering and absorption on spectra observed at balloon altitudes. Compton and coherent scattering and photoelectric absorption are taken into account in the calculation. The results show that exponential-type x-ray energy spectra steepen on penetration through the atmosphere in the energy range 50 to 200 keV due to the fact that the majority of x rays reaching typical balloon altitudes between 5 and 20 g/cm^2 have suffered energy degradation from Compton scattering. The slope of the spectrum indicated by a collimated detector is found to be more dependent on source geometry and detector source distance than it is for an omnidirectional detector. In fact, the latter detector causes almost constant and hence predictable spectral distortion, irrespective of source geometry or detector–source distance. Data are provided from which can be deduced the parent x-ray spectrum and flux from balloon measurements for different atmospheric depths, detectors, source geometries, and energy spectra. (auth)

58869 NUMERICAL CALCULATION OF REFLECTION AND TRANSMISSION COEFFICIENTS FOR THIN HIGHLY IONISED LAYERS INCLUDING THE EFFECT OF THE EARTH'S MAGNETIC FIELD. **Chessell, C. I. (Univ. of Melbourne). J. Atmos. Terrest. Phys.; 33: No. 10, 1515-32(Oct 1971).**

A numerical integration process is described which can be used to calculate reflection and transmission coefficients for thin highly ionized layers in the presence of the Earth's magnetic field. Comparisons are made with the results of phase integral methods and the importance of mode coupling demonstrated. Complete reflection and transmission coefficient results are presented for a thin parabolic layer. (auth)

58870 MAGNETO-IONIC MODE COUPLING OF hf RADIO WAVES. **Titheridge, J. E. (Univ. of Auckland, N. Z.). J. Atmos. Terrest. Phys.; 33: No. 10, 1533-40(Oct 1971).**

The effect of coupling between the ordinary (O) and extraordinary (E) components is examined using the coupled wave equations. The coupling in any region is said to be critical when, for initial O and E modes of equal amplitude, the relative phase of the O and E modes emerging from the region is constant and independent of the initial phase. Under these conditions a pure O (or E) wave entering the coupling region emerges as O and E components of equal amplitude. When coupling is greater than the critical value, an increasing phase difference between the initial O and E components becomes a decreasing phase difference after passage through the coupling region. This change produces a reversal in the sign of the Faraday rotation. For a constant value of the coupling ratio Q, critical coupling can occur only if $Q > 1$ over an appreciable distance. When coupling is caused by a steady change in the angle θ between the wave normal and the magnetic field, the overall effect depends only on the peak value of Q (at $\theta = 90°$). (auth)

58871 MODE COUPLING OF hf WAVES IN THE IONOSPHERE. **Titheridge, J. E. (Univ. of Auckland, N. Z.). J. Atmos. Terrest. Phys.; 33: No. 10, 1541-57(Oct 1971).**

Coupling of the ordinary (O) and extraordinary (E) modes in the ionosphere occurs when the angle θ between the wave normal and the magnetic field varies along the ray path. The degree of coupling is specified by a coupling ratio Q. This reaches a maximum at the transverse point ($\theta = 90°$) and coupling is generally confined to a limited region near this point. The overall effect of this coupling region is evaluated using the coupled wave equations. If the peak value of Q(Q_m, at $\theta = 90°$) is greater than 2.3, the Faraday rotation of a signal traversing the coupling region is approximately zero. If $Q_m < 2.3$ the polarization ellipse is reversed at $\theta = 90°$ and the absolute number of Faraday rotations increases throughout the ray path. The coupling then causes a slight increase in the amount of Faraday rotation. Curves are given showing the variation of Q with height in the ionosphere and with zenith angle, for different directions of propagation at latitudes of 2 to 40°. The value of Q_m is primarily a function of height. For a typical F layer with a penetration frequency of 10 MHz and a wave frequency of 40 MHz, $Q_m > 2.3$ only for heights above 500 km or below 200 km at all latitudes. The effect on the Faraday rotation of satellite signals is calculated. (auth)

58872 INTERACTION OF INTERNAL GRAVITY WAVES WITH THE IONOSPHERIC F2 LAYER. **Clark, R. M.; Yeh, K. C.; Liu, C. H. (Univ. of Illinois, Urbana). J. Atmos. Terrest. Phys.; 33: No. 10, 1567-76(Oct 1971).**

A gravity wave produces perturbations in density, velocity, and temperature in the neutral atmosphere. These perturbations in turn modify the ionospheric processes involving photoproduction, chemistry, and transport. The effect of modification of these processes on the F2 ionosphere can be examined by solving numerically the equation of continuity. Extensive computations have shown that the ionospheric response at F2-region heights is quite sensitive to ion drag and diffusion effects. To neglect diffusion may introduce a substantial height-dependent phase shift. It has been found that a gravity wave of perturbation magnitude may induce an ionization change which is not of perturbation magnitude. Under such circumstances, the perturbation analysis cannot be expected to obtain ionospheric response with any desired accuracy for all cases. The phase of atmospheric parameters relative to the ionization perturbation is found to vary continuously with height. (auth)

58873 EFFECT OF EARTH'S MAGNETIC FIELD ON PROPAGATION OF ELF AND VLF RADIO WAVES. **Barr, R. (London Univ.). J. Atmos. Terrest. Phys.; 33: No. 10, 1577-83(Oct 1971).**

Computations were made of the attenuation and phase velocity of elf and vlf radio waves propagating under a realistic inhomogeneous anisotropic ionosphere. By assuming the ionosphere to be representative of the daytime ionosphere at all latitudes and the Earth's magnetic field to be that of a perfect dipole, the azimuthal dependence of elf and vlf propagation was studied as a function of latitude. The azimuthal variation of the propagation constant of the Earth–ionosphere waveguide was found to increase with decreasing latitude, the greatest variation occurring at "attenuation band" frequencies (1 to 4 kHz). A modal degeneracy dependent upon azimuth and latitude was also observed. It is predicted that modal interference will occur at vlf, the effect being greatest for west–east propagation and increasing with decreasing latitude. (auth)

58874 CHARACTERISTICS OF STORM-TIME GEOMAGNETIC DAILY VARIATION. **Kane, R. P. (Physical Research Lab., Ahmedabad, India). J. Atmos. Terrest. Phys.; 33: No. 10, 1585-95(Oct 1971).**

Quiet and disturbed-day daily variations (Sq, Sd) and their difference SD = Sd – Sq are studied for the H component for 1964 for Sverdlovsk, Alibag, Annamalainagar, and Trivandrum (all in 60 to 80°E longitude) after correcting for D_{st} effects which are estimated in two ways; (i) D'_{st} obtained as average of Tashkent and Sabhawala near the Sq focus; and (ii) D''_{st} obtained from SUGIURA and CAIN (1970). The results show that (a) Sq is a predominantly day-time phenomenon of mostly ionospheric origin, (b) SD is diurnal for mild disturbances and semi-diurnal for large disturbances and consists of a morning increase, a sharp noon decrease giving a reverse current, a recovery to positive current by 20 to 22 hr LT, followed by a decay to zero level. Implications regarding ionospheric and non-ionospheric contributions are discussed. (auth)

58875 PHASE-INTEGRAL CORRECTION FOR CALCULATIONS OF RADIO-WAVE ABSORPTION IN THE IONOSPHERE. **Thorpe, M. R. (Univ. of Canterbury, Christchurch, N. Z.). J. Atmos. Terrest. Phys.; 33: No. 10, 1597-1605(Oct 1971).**

The absorption of radio waves reflected in the ionosphere may be calculated by the phase integral method. An analytic expression is derived for the phase integral correction to the absorption as calculated by ray theory. The expression is shown to be of adequate accuracy for most conditions of propagation, and represents a correction of about 10% for frequencies near 2 MHz. (auth)

58876 SOME PULSE CHARACTERISTICS OF ATMOSPHERIC RADIO-NOISE BURSTS AT 3 MHz. **Shivaprasad, A. P. (Indian Inst. of Science, Bangalore). J. Atmos. Terrest. Phys.; 33: No. 10, 1607-19(Oct 1971).**

An atmospheric radio-noise burst represents the radiation received from one complete lightning flash at the frequency to which a receiver is tuned and within the receiver bandwidth. At tropical latitudes, the principal source of interference in the frequency range from 0.1 to 10 MHz is the burst form of atmospheric radio noise. The structure of a burst shows several approximately rectangular pulses of random amplitude, duration, and frequency of recurrence. The influence of the noise on data communication can only be examined when the value of the number of pulses crossing a certain amplitude threshold per unit time of the noise burst is known. A pulse-rate counter designed for this purpose was used at Bangalore (12°58′N, 77°35′E) to investigate the pulse characteristics of noise bursts at 3 MHz with a receiver bandwidth of 3.3 kHz/6dB. The results show that the number of pulses lying in the amplitude range between peak and quasi-peak values of the noise bursts and the burst duration corresponding to these pulses follow log normal distributions. The pulse rates deduced therefrom show certain correlation between the number of pulses and the duration of the noise burst. The results are discussed with a view to furnish necessary information for data communication. (auth)

58877 UPWARD-MOVING IRREGULARITIES IN THE SUB-EQUATORIAL IONOSPHERE. **Faynot, J. M.; Vila, P.; Walter, J. (GRI–CNET, Issy-les-Moulineaux, France). J. Atmos. Terrest. Phys.; 33: No. 10, 1621-7(Oct 1971).**

Upward-rising equatorial strata, differing from other h′(f) structures, are described. The rising motion, analyzed by N(h) profiles, can be explained at F2-region levels by Hall drift from the daytime west–east electric field. Day-to-day and seasonal variations are discussed. (auth)

58878 HEIGHT AND FREQUENCY VARIATION OF PENETRATING AND NON-PENETRATING MODES IN THE IONOSPHERE. **Altman, C.; Postan, A. (Technion–Israel Inst. of Tech., Haifa). J. Atmos. Terrest. Phys.; 33: No. 10, 1629-39 (Oct 1971).**

A thin-film optical method is adapted to determine the full-wave reflection and transmission coefficients, R_p, R_{np}, τ_p and τ_{np} of the "penetrating" and "non-penetrating" modes vertically incident from below on a horizontal ionospheric slab whose base is the bottom of the ionosphere and which follows the given variation of the ionospheric parameters up to the top of the slab, above which it passes continuously into a homogeneous semi-infinite medium. The thin-film optical method is based on the iterative variation of the height, h, of the top of the slab, and the technique thus yields the full-wave reflection and transmission coefficients as functions of the height, h, of the upper slab-face. The wave polarizations of the incident penetrating and non-penetrating modes are such as to yield maximum and minimum energy transmission respectively, high in the ionosphere. For frequencies less than the critical coupling frequency or somewhat above it it was found, for the total ionosphere, that $R_{np} > R_p$, almost the entire contribution to both the reflection coefficients coming from the $X = 1 + Y$ level. For frequencies very much greater than the critical coupling frequency, however, the behavior of the reflection coefficients is more complex. When the height of the upper slab-face is just above the $X = 1$ level, $R_{np} > R_p$, whereas for the total ionosphere, i.e., for heights extending beyond the $X = 1 + Y$ level, $R_p > R_{np}$. The unexpected result is explained in terms of the behavior of the characteristic waves composing the penetrating and non-penetrating modes. (auth)

58879 SEMIANNUAL VARIATION IN HEIGHT OF F2-LAYER PEAK. **Eccles, D.; King, J. W.; Kohl, H.; Pratt, R. J. (Radio and Space Research Station, Slough, Eng.). J. Atmos. Terrest. Phys.; 33: No. 10, 1641-6(Oct 1971).**

Noon values of h_mF2 were calculated for two midlatitude stations for the fifteenth day of each month in 1958. The theoretical variations of the layer height during the year are found to be similar to those observed only when the semiannual variation of exospheric temperature and the effects of neutral-air winds are taken into account in the calculations. The calculated and observed f_0F2 variations are, however, completely different, indicating that some mechanism exists which exerts a controlling influence on the electron concentrations without seriously affecting the height of the layer peak. (auth)

58880 REGULAR AND IRREGULAR BEHAVIOUR OF THE WINTER ANOMALY IN IONOSPHERIC ABSORPTION. **Schwentek, H. (Max-Planck-Institut fuer Aeronomie, Lindau, Ger.). J. Atmos. Terrest. Phys.; 33: No. 10, 1647-50(Oct 1971).**

It is demonstrated that in winter, at middle latitudes, three different types of absorption occur. On few days, absorption is as small as in summer. Secondly, there are a considerable number of days on which absorption follows a regular trend, increasing from the end of September to the winter solstice, then decreasing until the end of March. Finally, there are a greater number of groups of days, and also of single days, on which absorption is very high. These groups of days of excessive absorption appear sporadically, that is, at times different from winter to winter. (auth)

58881 MEASUREMENT OF THE THICKNESS OF A SPORADIC-E LAYER. **Kantarizis, E. (Univ. of Queensland, Brisbane). J. Atmos. Terrest. Phys.; 33: No. 10, 1651-6(Oct 1971).**

A method is described for measuring the thickness of a sporadic E layer from records obtained when using a phase ionosonde. The method involves the measurement of the phase advance, caused by the presence of a sporadic E layer, on echoes from the F region. One example is analyzed in detail and it was found that the sporadic E layer was a sharp-peak layer, and its thickness at a plasma frequency equal to 90% of its critical frequency was 5 km. The thickness of the same sporadic E layer was also measured independently by performing a true-height reduction, by a polynomial method, using the phase of the echoes from the E region of the ionosphere. The results obtained from the two methods were consistent. (auth)

58882 PENETRATION OF MAGNETOSHEATH PLASMA TO LOW ALTITUDES THROUGH THE DAYSIDE MAGNETOSPHERIC CUSPS. **Winningham, John David. College Station, Tex.; Texas A and M Univ. (1970). 298p. University Microfilms Order No. 71-17,849.**

Thesis.

Daytime high-latitude fluxes of low-energy (<1 keV) electrons and protons were observed with the soft-particle spectrometer on the polar satellite ISIS-I. These fluxes occur just above the limit Λ_{CL} of closed geomagnetic field lines in the dayside magnetosphere. The boundary, Λ_{CL}, can be identified through a sharp decrease in the flux of electrons of somewhat higher energy (~10 keV). The electron energy spectrum shows a sharp peak at about 100 to 200 eV, with a total flux of the order of 10^9 electrons cm^{-1} $ster^{-1}$ sec^{-1} carrying an energy of a few tenths of an erg cm^{-2} $ster^{-1}$ sec^{-1}. The electron and proton spectral shapes are shown to be similar to those in the magnetosheath and, for protons, the absolute intensities are approximately equal (no absolute intensities could be found in the literature for electrons). The proton spectrum peaks at a slightly higher energy (~300 eV) again in agreement with magnetosheath observations. The proton flux is typically $>10^7$ cm^{-2} $ster^{-1}$ sec^{-1} with typical energy fluxes in the range 0.01 to 0.1 ergs cm^{-2} $ster^{-1}$ sec^{-1}. It is concluded that solar-wind plasma can penetrate to low altitudes through the high-latitude cusp in the magnetopause, often referred to as the neutral point. (Diss. Abstr. Int., B)

58883 SPECTROPHOTOMETRY OF THE NIGHT AIRGLOW AND THE AURORAE. **Sivjee, Gulamabas Gulamhusen. Baltimore; Johns Hopkins Univ. (1970). 216p. University Microfilms Order No. 71-16,749.**

Thesis.

Spectrophotometric studies of the nightglow and auroral emissions were carried out aboard NASA's jet aircraft CV 990, the "Galileo," from Jan.–Mar. 1968 and again in Nov.–Dec. 1969. To complement the airborne experiments, ground-based measurements of the nightglow OH rotational temperature were made at Laurel Observatory in Pennsylvania during June–Dec. 1968 and Howard County in Maryland between June–Oct. 1969. A one-meter Ebert spectrometer and a five-channel photometer were employed. The nightglow OH data has revealed (a) local time variation in OH rotational-temperature and intensity, (b) latitude and seasonal variations in OH rotational-temperature, (c) covariation between the intensities of OH and 5577, (d) an occasional, preferential enhancement of OH rotational levels with rotational quantum numbers greater than 4, (e) covariation between intensities of OH and Herzberg I bands of O_2, and (f) the absence of any auroral enhancement in OH emissions. The OH intensity has also been found to be independent of H_α and 6300 radiations. The auroral data have shown that the red bands of $N_2$1PG in type-B aurora are formed by electron excitation. A study of intensity ratio of the (0–1) and (1–2) bands of the N_2^+ first negative bands as a probe for low energy protons in auroras is presented. (TSS) (Diss. Abstr. Int., B)

58884 DISTRIBUTION OF NIGHTTIME F-REGION MOLECULAR ION CONCENTRATIONS AND 6300 A NIGHTGLOW MORPHOLOGY. **Brasher, William Ernest. Denton, Tex.; North Texas State Univ. (1970). 97p. University Microfilms Order No. 71-18,649.**

Thesis.

Spatial and temporal distributions of molecular ions in the nighttime F-region of the ionosphere and the morphology of the associated 6300-Å nightglow are investigated. Ionospheric and nightglow models are developed for calculating the dominant ion concentration profiles and nightglow intensities. A numerical technique is employed in solving the coupled, nonlinear system of equations for the O^+, NO^+, and O_2^+ number densities in the nighttime F-region, including the effects of diffusion, electromagnetic

XUM

drift, minor neutral constituents, and neutral air motions. The dependence of the molecular ion profiles on the various ionospheric and atmospheric parameters that affect their distributions is determined. The correlation of specific ionospheric parameters with 6300-Å nightglow intensity during periods of magnetically quiet and disturbed conditions is demonstrated. The solutions to the ion concentration equations are compared with two types of ionospheric observations: (1) midlatitude mass spectrometer observations of the nighttime ion profiles at White Sands, New Mexico; and (2) the inter-tropical 6300-Å nightglow morphology observed at Tamanrasset, Africa. (TSS) (Diss. Abstr. Int., B)

58885 POSSIBILITY OF USING A QUADRUPOLE PROBE FOR MEASURING ELECTRIC CURRENTS IN THE MAGNETOSPHERE. **Storey, O.; Pottelette, R. (Centre National de la Recherche Scientifique, Saint-Maur-des-Fosses, France). Compt. Rend., Ser. B; 273: No. 2, 101-4(12 Jul 1971). (In French).**

The transfer impedance of a quadrupole probe is affected by its motion with respect to the plasma. This effect was studied on one of the oblique resonances of the transfer impedance. The results show that it is possible to measure the velocity of the thermal flux parallel to the magnetic field in the magnetosphere, and therefore obtain the value of the electron current. (France)

58886 INTERPLANETARY MEDIUM AND ITS INTERACTION WITH THE EARTH'S MAGNETOSPHERE. **Kovalevskii, I. V. (Inst. of Terrestrial Magnetism, Ionosphere, and Radio Wave Propagation, Moscow). Space Sci. Rev.; 12: No. 2, 187-257(Jun 1971).**

The principal results of direct measurements of the plasma and magnetic field by spacecraft close to the Earth (within the heliocentric distance range 0.7 to 1.5 AU) are reviewed. An interpretation is given of the results for periods of decrease, minimum, and increase of the solar activity. The following problems are discussed: the interplanetary plasma (chemical composition, density, solar-wind flow speed, temperature, and temporal and spatial variation of these parameters); the interplanetary magnetic field (intensity, direction, fluctuations, and its origin); some derived parameters characterizing the physical condition of the interplanetary medium; the quasi-stationary sector structure and its relation with solar and terrestrial phenomena; the magnetohydrodynamic discontinuities in the interplanetary medium (tangential discontinuities and collisionless shock waves); the solar magnetoplasma interaction with the geomagnetic field (the collisionless bow shock wave, the magnetosheath, the magnetopause, the Earth's magnetic tail, and the internal magnetosphere characteristics); the relation between the geomagnetic activity and the interplanetary medium and magnetosphere parameters; peculiarities in behavior of the interplanetary medium and magnetosphere during geomagnetic storms; and energetic aspects of the geomagnetic storms. (auth)

58887 EFFECTS OF MAGNETIC STORMS ON ELECTRIC POWER SYSTEMS. **Tripathy, Sarat Chandra. Minneapolis; Univ. of Minnesota (1970). 149p. University Microfilms Order No. 71-18,829.**
Thesis.

Geomagnetic disturbances causing operating problems on electric power systems such as voltage fluctuations and large reactive flow are primarily due to the fact that geomagnetic disturbances produce an induced Earth surface potential, which in turn produces spurious currents in long lines and equipment that are in some way grounded. With the trend toward longer lines and interconnected power systems over large geographical areas of the country, some of the problems caused by geomagnetic disturbances have become more acute. The induced Earth surface potential (ESP) has been statistically correlated with K index, which defines the intensity of the magnetic storms. The solar induced currents (SIC) flow through the phase windings of 3-phase power transformers and give a dc bias to the core flux in the transformers causing saturation on half-cycles of the ac wave. The consequences of this saturation are variations in voltage, watt, and var flow on the system, localized internal heating in the transformer, and generation of harmonics. The effects of core saturation of power transformers were studied. In searching for likely methods of mitigation of SIC, one possibility appears to be the insertion of a nonlinear resistance element, such as thyrite in the transformer neutral. Ideally, such an element inserted in the neutral should (1) limit the SIC and (2) keep the system voltage at reasonable levels under fault conditions. The connection of thyrite in the neutral of power transformer will cause undesirable voltage transients under fault and switching conditions. (TSS) (Diss. Abstr. Int., B)

58888 CORRELATIONS BETWEEN SUDDEN PHASE ANOMALIES IN VERY LONG WAVES AND BURSTS OF SOLAR X RAYS. **Kimpara, Atsushi; Nishiwaki, Akira. Compt. Rend., Ser. B: 272: No. 26, 1493-5(28 Jun 1971). (In French).**

A severe world ionospheric storm was observed on Mar. 8, 1970 during a world geophysical period. Sudden phase anomalies (SPA) and sudden enhancements of the field (SEF) associated with signals from the Australian Northwest Cape emitter (223 Hz) were observed over a long period of time. In particular, the characteristics of the phase anomalies occurring during this period were examined. (France)

58889 UNIFORM ELECTRICAL CONDUCTIVITY MODEL FOR THE EARTH AND THE GEOMAGNETIC DISTURBANCE DAILY VARIATION. **Petersons, H. F. (Australian National Univ., Canberra). Aust. J. Phys.; 24: 593-600(Aug 1971).**

Chapman's uniform conducting core model has been investigated using S_q and SD results for the IGY. Values for the conductivity and core radius could not be found for which there was agreement between the S_q and SD results at the likely 95% confidence limit of S_q and, consequently, either the uniform core model is inadequate for representing S_q and SD or the errors in the analysis of S_q and SD are larger than estimated statistically. In the latter case a value for the conductivity σ of 1.5×10^{-12} emu and for q of 0.99 (where q is the ratio of the radius of the core to that of the Earth) would then be indicated. (auth)

58890 MEASUREMENTS OF RADIATION-BELT PROTONS IN THE ENERGY RANGE 0.25 TO 1.65 MeV ON BOARD THE SATELLITE AZUR. **Moritz, J. (Christian-Albrechts Univ., Kiel). Z. Geophys.; 37: 179-94(1971). (In German).**

Directional proton intensities in the energy range 0.25 to 1.65 MeV are measured with an experiment on board the satellite Azur (1969–97A). A telescope with two solid-state detectors of equal size, 7 mm in diameter and 34-micron thick, is used. The associated electronics allows for energy discrimination at 0.25, 0.5, 1.0, and 1.65 MeV in the total energy range of 0.25 to 13.5 MeV. The directionality is defined by a mechanical aperture that incorporates a broom magnet to suppress low-energy electrons. Direct interpretation of the count rates as particle intensities is possible only at L values greater than 1.9 and gives good agreement with earlier measurements. Within the inner radiation belt ($L < 1.9$) the count rates have to be corrected for a background due to higher-energy protons and electrons whose magnitude can be derived from the count rate of one of the detectors. The count-rate correction leads to low proton intensities within the inner radiation belt and a rising energy spectrum in the energy range 0.25 to 1.65 MeV. (auth)

58891 PROTON MEASUREMENTS IN THE MORNING SECTOR OF THE AURORAL ZONE DURING SLOWLY VARYING COSMIC NOISE ABSORPTION. **Raethjen, H. (Univ., Kiel). Z. Geophys.; 37: 195-210(1971). (In German).**

Two rockets were launched from Andenes, Norway and the energy spectrum of incoming protons was directly measured on board these rockets up to > 200 km. The differential spectrum in the energy range 130 to 450 keV can approximately be represented by the exponential law $d\Phi = \Phi_0 \exp(-E/E_0)dE$. E_0 changed from 80 to 50 keV as the absorption decreased from 2.6 to 1.7 db. The maximum integral intensity for $E > 135$ keV was 4×10^3 p/cm^{2}sec ster for 2.6 db absorption. The intensity was by a factor of 10 smaller when the absorption had decreased to the almost quiet-time level. No significant anisotropy could be observed within the small pitch-angle area included. (auth)

58892 SOLAR PARTICLE EVENT OF MARCH 1970 AS OBSERVED OVER THE POLAR CAP AND IN THE RADIATION BELT WITH THE SATELLITE GRS-A/AZUR. **Achtermann, E.; Haeusler, B.; Hovestadt, D.; Scholer, M. (Max-Planck-Institut fuer Physik und Astrophysik, Garching, Ger.). Z. Geophys.; 37: 211-23(1971).**

Experimental results on energetic electrons, protons, and alpha particles are presented for the March 1970 solar particle events. The data were obtained on board the polar orbiting satellite GRS-A/AZUR by two particle telescopes for protons and alpha particles and two omnidirectional detectors for electrons and protons. The energy ranges are 1.5 to 104 MeV for protons, 6 to 19 MeV for alpha particles, and $E > 1.5$ MeV and $E > 4$ MeV for electrons. The time history of the solar particle event, the proton-to-alpha ratio, and its variation during the event, the occurrence of delayed penetration of particles into the central polar cap region, and the apparent inward motion of outer-belt electrons associated with the event are discussed. (auth)

58893 ISSLEDOVANIYA ATMOSFERY I IONOSFERY V PERIOD POVYSHENNOI SOLNECHNOI AKTIVNOSTI (MART-APREL' 1969 g.). SBORNIK STATEI. (Studies of Atmosphere and Ionosphere at Times of Unusual Solar Activity (March-April 1969). Collection of Articles). Mikhnevich, V. V.; Danilov, A. D. (eds.). Leningrad; Gidrometeorologicheskoe Izdatel'stvo (1970). 160p.

The measurements of atmospheric and ionospheric characteristics by rockets and radio soundings in periods of vigorous solar activity during March–April, 1969, are collected and reviewed by a number of authors. Ground-level measurements are included. Correlations between solar activity, corpuscular currents, atmospheric ionization, and the structures of the upper and lower atmospheres of the Earth are made. (K.S.W.)

58894 RECENT DEVELOPMENTS IN THEORY OF SOLAR WIND. Parker, E. N. (Univ. of Chicago). Rev. Geophys. Space Phys.; 9: No. 3, 825-35(Aug 1971).

Current problems and developments in the theory of the large-scale expansion of the solar corona are reviewed. The outstanding question is whether the energy supply to the quiet corona is mainly thermal conduction outward from a region of active heating at its base or mainly wave propagation outward from the base. It is suggested that the question can be settled only when the properties of the wind can be sampled over a wide range of radial distance from the Sun, from far inside the orbit of Earth to well beyond. It has been suggested that hydromagnetic waves may drive the expansion of the active corona by direct transfer of momentum as well as energy. 72 references. (auth)

58895 PLASMA INSTABILITIES IN THE MAGNETOSPHERE. Hasegawa, Akira (Bell Telephone Labs., Inc., Murray Hill, N. J.). Rev. Geophys. Space Phys.; 9: No. 3, 703-72(Aug 1971).

An introductory review of theories of plasma instabilities in the magnetosphere is presented. Part A is a review of theories of plasma instabilities that are relevant to magnetospheric plasmas. Instabilities arising from velocity-distribution anisotropies, such as a pitch-angle anisotropy or the presence of beams, as well as instabilities from nonuniform distributions of plasmas and magnetic fields, are discussed. Particular emphasis is placed on the effect of a mixture of a cold plasma in a high-β plasma. Part B is a summary of works related to actual plasma instabilities in the magnetosphere. In view of the observed plasma parameters, it is shown that the magnetosphere is rather stable against most macroscopic instabilities, and its dynamics are predominantly governed by microscopic instabilities. 132 references. (auth)

58896 PATTERNS AND SOURCES OF HIGH-LATITUDE PARTICLE PRECIPITATION. Paulikas, G. A. (Aerospace Corp., El Segundo, Calif.). Rev. Geophys. Space Phys.; 9: No. 3, 659-701(Aug 1971).

The zones of particles precipitated into high latitudes from the outer magnetosphere are studied to associate source regions, and, if possible, precipitation mechanisms with each of the families of precipitating particles that collectively form the auroral zone. The precipitation patterns for both electrons and protons exhibit a diurnal variation. The several zones of particle precipitation can be placed in relationship to each other. The zone of electron precipitation is best described as consisting of a region at low latitudes ($60° \lesssim \Lambda \lesssim 70°$ near local midnight) where electrons with characteristic energies of tens of keV precipitate; this region merges and overlaps at the higher latitudes with another region ($70° \lesssim \Lambda \lesssim 80°$ near local midnight) characterized by precipitating electrons of ≈ 0.5 keV. The limited data available indicate that the zone of proton precipitation spatially overlaps the zone of electron precipitation. Near local noon a separate region of very soft proton precipitation is found in the vicinity of $\Lambda \approx 80°$, in addition to a region of proton influx at lower latitudes. The plasma sheet, the extraterrestrial ring current, the polar cusp, and the outer radiation belt are considered as source regions of precipitating particles. Brief surveys of the precipitation of helium ions and of possible means of artificially inducing particle precipitation are also included. 133 references. (auth)

58897 ENERGETIC ELECTRON PRECIPITATION NEAR THE PLASMAPAUSE. Rosenberg, T. J. (Univ. of Maryland, College Park). Antarctic J. U. S.; 6: No. 4, 131(Jul-Aug 1971).

Bremsstrahlung x radiation was measured at Siple Station during the 1970–1971 austral summer to study energetic electron precipitation from the magnetosphere. The degree of correlation was determined between energetic electron precipitation as manifested by bremsstrahlung x rays at balloon heights and various types of vlf emissions recorded by ground-based receivers. The plasmapause is a region of enhanced wave activity and a likely area to find a high degree of correlation between temporal features in electron precipitation and vlf noise. The equatorward extent of electron precipitation events associated with magnetic storms and substorms was examined to determine if it coincides with the position of the plasmapause. It was found that short duration bursts of x rays with energies greater than 30 keV were correlated one-to-one with discrete vlf rising tones in the 1.5- to 4.5-k Hz band and perhaps represent the first experimental evidence for an electron precipitation effect related to cyclotron resonance on magnetospheric-field lines. (J.C.W.)

58898 CONJUGATE GEOMAGNETIC STUDIES NEAR THE PLASMAPAUSE. Lanzerotti, L. J.; Lie, H. P.; Tartaglia, N. A. (Bell Telephone Labs., Murray Hill, N. J.). Antarctic J. U. S.; 6: No. 4, 129-31(Jul-Aug 1971).

The study of the conjugate magnetic field near the average plasmapause position will extend the magnetic bay studies of Boyd (1963) and the single-axis measurements of Campbell (1968). Present measurements were taken at Siple Station, Antarctica, and at three stations spaced at 70-km intervals on the north–south line in Quebec. Naturally occurring geomagnetic noise and coherent pulsations were analyzed. Data were analyzed following the large geomagnetic storm of Dec. 14, 1970. The dynamic power spectral analysis of the H-component shows no coherent pulsations during the observation on Dec. 15 and could be due to low plasma densities outside the plasmapause following the large storm. The observed reappearance of pulsations on later days suggests a filling of the plasmasphere, as observed in whistler measurements (Park, 1970). An observed similarity exists at all stations and the observed magnetic noise near conjugate locations in both hemispheres indicates a magnetospheric, rather than ionospheric, origin for the noise. (J.C.W.)

58899 INVESTIGATION OF THE IONOSPHERIC D REGION AT SUNRISE. Turco, Richard Peter Urbana, Ill.; Univ. of Illinois (1971). 295p. University Microfilms Order No. 71-21,255.

Thesis.

The growth over sunrise of the C and D layers of the ionosphere are investigated. The model which is analyzed includes the negative ion species O^-, O_2^-, O_3^-, O_4^-, NO_2^-, NO_3^-, CO_3^-, and CO_4^-; ionization sources due to galactic cosmic rays, precipitated electrons, ionization of NO by scattered Lyman-α radiation, and the direct solar-radiation ionization of NO and $O_2(^1\Delta g)$; the photodetachment of most of the negative ions; and the time variation of all of these parameters. Also calculated are the detailed sunrise behaviors of the neutral atmospheric species O, O_3, and $O_2(^1\Delta g)$. The time variations of the electron, negative ion, and positive ion densities are calculated over sunrise. From these data the mesospheric C- and D-layer development is plotted. Several model parameters are varied until the best agreement with experimentally determined electron densities is obtained. The results are discussed in light of several atmospheric parameters including the O and NO concentrations and the electron–ion recombination coefficient. (Diss. Abstr. Int, B)

58900 ELECTROSTATIC PLASMA INSTABILITIES IN THE EQUATORIAL ELECTROJET. Prakash, S.; Gupta, S. P.; Subbaraya, B. H.; Jain, C. L. (Physical Research Lab., Ahmedabad, India). Nature (London) Phys. Sci.; 233: No. 38, 56-8(20 Sep 1971).

It is stated that, during the flights of two Nike Apache rockets launched from Thumba, India on Jan. 28, 1971 and carrying Langmuir probes and other aeronomy payloads, large- and small-scale irregularities in electron density were observed. Above 100 km the amplitude of the large-scale irregularities decreased, whereas the opposite was the case for the small-scale irregularities. Results are given for the small-scale irregularities of scale sizes 1 to 15 m in the 87- to 98-km region. Spectral indices are shown graphically, and mechanisms are discussed. It appears that another mechanism may have been operating simultaneously with cross-field instability, and in this connection, electrostatic plasma instabilities in the equatorial electrojet are discussed. Simultaneous measurements of electrojet currents could not be made, but extrapolated values from another flight are used in the discussion. The amplitude of irregularities in the 105-km region correlated well with the intensity of the electrojet currents. (UK)

58901 SIMULTANEOUS SUDDEN FREQUENCY DEVIATIONS AND SUDDEN ENHANCEMENTS OF THE TOTAL ELECTRON CONTENT OF THE IONOSPHERE. Papagiannis, M. D.; Matsoukas, D. A. (Boston Univ.). Nature (London) Phys. Sci.; 233: No. 38, 55-6(20 Sep 1971).

A direct comparison is reported between sudden increases of the total electron content (SITEC) of the ionosphere during solar-flare events and sudden frequency deviations (SFD). The SITEC data were obtained at the Sagamore Hill AFCRL radio observatory,

XUM

using the vhf signals of the ATS-3 and -5 geostationary satellites, and the SFD data were recorded at Boulder, Colorado. Analysis was performed for the period Jan. 1969 to July 1970. It was found that the probability of an SFD accompanying a simultaneous SITEC increased rapidly with increasing peak frequency deviation. Also investigated was the time correspondence of SFD and SITEC events; the rise time from start to maximum was found to be nearly the same (~2 min) for both. The time of the peak frequency deviation appeared to coincide with the time of the maximum rate of change in TEC (total electron content). The chief contribution to the enhanced TEC appears to be produced in the F1 and F2 regions. The results suggest that both SITEC and SFD phenomena are manifestations of enhanced ionization produced by the same euv-flare emission in the same region of the ionosphere. (UK)

58902 STUDY OF THE (4-1) AND (5-2) HYDROXYL BANDS IN THE NIGHT AIRGLOW. **Harrison, A. W. (Univ. of Calgary, Alberta); Evans, W. F. J.; Llewellyn, E. J. Can. J. Phys.; 49: No. 19, 2509-17(1 Oct 1971).**

A one-year study of the (4−1) and (5−2) hydroxyl bands in the night airglow near 1 μ revealed a nonuniform rotational temperature across the P branch of each band. The temperature increases with K' value. There is a pronounced seasonal variation of temperature showing a summer minimum and winter maximum. The average measured brightness for the (4−1) band is 4.6 kR (winter) and 3.5 kR (summer), and for the (5−2) band is 5.8 kR (winter) and 4.3 kR (summer). It is shown that the time-averaged total band intensity fluctuations during a single night are quite large, sometimes a factor of 2, and are not definitely correlated with the rotational temperature during the same period. (auth) (Canada)

58903 SOME CHARACTERISTICS OF IRREGULAR MICROPULSATIONS Pi2 AT HIGH-LATITUDE STATIONS. **Gupta, Jagdish C.; Stening, Robert J. (Dept. of Energy, Mines, and Resources, Ottawa). Can. J. Phys.; 49: No. 18, 2338-49(15 Sep 1971).**

Pi2 micropulsations were studied for the period July 12 to August 16, 1968, from four observatories at different latitudes in Canada. Maximum occurrence was near midnight with a preference for 5−6 hr UT at all longitudes studied. The relationship of Pi2 occurrence to magnetic bays and to Kp is examined. The correlation of Pi amplitudes and periods with Kp and other parameters reveals a different pattern for lower-latitude stations (Ottawa and Meanook) compared with Baker Lake (73.9°N). These results are interpreted as evidence for two different types of Pi in the different-latitude regions, the lower latitude Pi being associated with hydromagnetic waves on the plasmapause. In studies of simultaneous Pi events at the four stations, the maximum amplitude occurred most frequently at Meanook. Polarization of such events was found to be different at different stations, therefore previously reported patterns of Pi polarization could not be confirmed. (auth) (Canada)

58904 PITCH-ANGLE DISTRIBUTION OF FAST ELECTRONS. **Miyazaki, Yukio; Takeuchi, Hajime; Imai, Takashi; Watanabe, Setsuko (Inst. of Physical and Chemical Research, Wako, Japan). Tokyo Daigaku Uchu Koku Kenkyusho Hokoku; 7: No. 1, 133-44(Mar 1971). (In Japanese).**

Local pitch-angle distribution of electrons was measured in a region lower than the radiation belt at low latitude. Results show that the electrons were captured by lines of magnetic force with considerably acute pitch angle at altitude from 350 to 1200 km. If $\sin^n \alpha$ is assumed for the distribution, the exponent n is 10 or more. Intensity of high-energy electrons (≳500 keV) showed longitudinal effect of factor 2 at 140 and at 160°E, and the distribution at 160°E was more flat. Comparison was made at altitude of 1000 km. Differential energy spectra in the range of 100 to 500 keV is proposed as about $E^{-2.75}$ at an altitude from 800 to 1200 km. (Japan)

58905 EFFECT OF MAGNETIC ACTIVITY ON ELECTRON DRIFTS IN EQUATORIAL ELECTROJET REGION. **Rastogi, R. G.; Chandra, H.; Misra, R. K. (Physical Research Lab., Ahmedabad, India). Nature (London) Phys. Sci.; 233: No. 36, 13-15(Sep 1971).**

Studies are described of the variations of electron-drift speed with magnetic activity at Thumba, near the magnetic equator and histograms are shown for the apparent drift speed in the E and F regions on five international quiet and five international disturbed days during 1964 and 1967−1968. In all cases the histograms are displaced towards lower drift values for disturbed days, and the drifts over the magnetic equator decrease with increased magnetic activity both for day and night hours. The E-region electron density being larger by a factor of about 100 during the day, the changes in drift speed would affect the electrojet currents and thereby the magnetic field at ground level mainly during the daytime hours. The total electrostatic field at low latitudes could decrease with increasing magnetic activity, explaining the decrease of electron drift with magnetic activity at low latitudes. (UK)

58906 UNSTABLE RADIATION ZONE: REGION WHERE AURORAL AND SEMITRAPPED PARTICLES ARE TRAPPED. **Troshichev, O. A. Cosmic Res. (USSR) (Engl. Transl.): 8: No. 6, 836-41(Nov-Dec 1970).**

Translated from Kosm. Issled.; 8: No. 6, 915-22(Nov-Dec 1970).

The distribution of charged particles in the magnetosphere beyond the radiation belts is examined. The concept of an unstable radiation zone, i.e., a special region containing auroral and semitrapped particles, is advanced and developed. It is shown that the space−time distribution pattern of auroral and magneto-ionospheric disturbances at high latitudes is governed by the specific features of the particle distribution in this unstable radiation zone. (auth)

58907 NONADIABATIC BEHAVIOR OF RADIATION-BELT PARTICLES. **Taylor, Harold E. (Princeton Univ., N. J.); Hastie, R. J. Cosmic Electrodyn.; 2: No. 2, 211-23(Jul 1971).**

The boundary of the trapping region is observed to be at lower latitudes for higher-rigidity particles, a type of inverse Stormer effect. This effect is studied for particles having large mirror ratios by numerically tracing particle orbits and investigating nonadiabatic jumps in the first invariant. Analytical expressions for these jumps are obtained for a dipole field, and a useful condition necessary for adiabaticity is obtained and applied to a more realistic model of the geomagnetic field. The numerical techniques applied to this realistic model predict the spatial profile and rigidity dependence of the boundary of the trapping region in the midnight meridian. The predicted boundary falls midway between the observed low-latitude cutoff of cosmic rays and the observed high-latitude boundary of the trapping region. (auth)

58908 EMPIRICAL DETERMINATION OF AERODYNAMIC FACTORS FOR THE MAGNETOSPHERE. **Schieldge, J. P.; Siscoe, G. L. (Univ. of California, Los Angeles). Cosmic Electrodyn.; 2: No. 2, 141-63(Jul 1971).**

The empirical drag coefficient, the north−south component of the lift due to the inclination of the dipole axis to the solar-wind direction, and the empirical shape of the magnetosphere were determined from satellite data associated with the five geomagnetically quiet days of each month for the first half of 1967. Twenty-eight days of Fourier-analyzed ATS-1 magnetic-field data and the averages of thirteen coincident days of Explorer 33 solar-wind data were used in the study. The magnetic-field gradient near the Earth is proportional to the solar-wind stagnation pressure. The theoretical drag coefficient agrees with the experimental result if the gradient field includes contributions from the Chapman−Ferraro currents, ring current, and tail currents. There is some evidence for a tilt-associated lift that is northward in the northern-hemisphere winter, consistent with that expected for supersonic aerodynamic flow about a smooth wing profile approximating calculated tilted dipole shapes of the magnetosphere. The empirical shape is calculated by an indirect method and corresponds reasonably well with theoretical predictions of the magnetopause geometry. Differences that occur suggest that the effective shape may be blunter because of additional wave drag and/or tangential forces on the magnetospheric tail. (auth)

58909 ELECTRIC COUPLING BETWEEN THE MAGNETOSPHERE AND THE IONOSPHERE AS A CAUSE OF POLAR MAGNETIC DISTURBANCES AND AURORAL BREAK-UP. **Oguti, Takasi (Tokyo Univ.). Cosmic Electrodyn.; 2: No. 2, 164-83(Jul 1971).**

Electric currents in the polar ionosphere are considered to be transient currents, with a characteristic time scale defined by ($C_M \cdot R_I$), the combination of a magnetospheric capacitance C_M and ionospheric Pedersen resistance R_I. This time scale is of the order of one hour for a large-scale electric current system such as the DP-2 field, and the phase lag of ionospheric currents is about 10 to 15 min behind the change in the solar wind. The mechanism of DP-2 development is interpreted as the charging of the magnetosphere, being positive on the dawn side and negative on the dusk side, and is produced by the polarization current in the solar wind. The auroral electrojet is attributed to an electric discharge along a filamental structure of auroral arcs. The discharge process is described in the following way. If any heterogeneity of conductivity appears in the polar ionosphere, it modifies

XUM

the DP-2 electric field. The modification results in a transient electric field parallel to the magnetic field. This field, in turn, can accelerate thermal particles and, accordingly, makes them precipitate. The precipitation of particles makes the heterogeneity of conductivity larger. Thus, a positive feedback loop is completed, and the precipitation and the discharge grows explosively, being associated with rapid acceleration of particles. The electric discharge lasts until the distribution of the electric field attains a new quasi-steady state. The acceleration of particles occurs between the magnetosphere and the ionosphere during the discharge process. Energetic particles, thus produced, cause the inflation of the magnetosphere and, also, are the origin of electron bursts in the magnetotail. A mechanism of the plasmapause formation is discussed in conjunction with the acceleration and precipitation of the thermal plasma in the outer magnetosphere. (auth)

58910 SOME PROCESSES IN THE MAGNETOSPHERE. Shabanskii, V. P. (Inst. of Nuclear Physics, Moscow). Space Sci. Rev.; 12: No. 3, 299-418(Jul 1971).

An earlier review of some magnetospheric processes by the author (Space Sci. Rev., 8: 366(1968)) is continued under the following headings: motion of the magnetic-field lines in plasma, electromagnetic processes in the magnetotail, and trapped-particle movement in the magnetospheric core. There are 115 references cited, 43 of which are Soviet papers. (J.C.W.)

58911 SURFACE-STATE LIFETIMES AND CURRENT FLOW IN LIQUID HELIUM. Williams, R.; Crandall, R. S. (Radio Corp. of America Labs., Princeton, N. J.). Phys. Rev., A; 4: No. 5, 2024-6(Nov 1971).

The lifetime of electrons trapped at the free surface of liquid ^{4}He was determined from the temperature dependence of the current flow in the liquid. These lifetimes are in substantial agreement with the values determined directly for the liquid/gas interface in ^{4}He. New results presented for the ^{4}He/^{3}He interface give lifetimes as long as 10^5 sec. (auth)

58912 PHENOMENOLOGICAL THEORY ON CRITICAL PHENOMENA IN LIQUID HELIUM. II. Ueyama, Hiroshi (Osaka Univ.). Progr. Theor. Phys. (Kyoto); 46: No. 1, 34-41(Jul 1971).

A method proposed previously is extended to problems of anomalous attenuation of the first and second sounds below the λ-point. Both of their damping constants are shown to have the contribution of the Landau–Khalatnikov absorption and that due to fluctuations of the order parameter. The former is the same as Usui's result and the latter is symmetric around the λ point. Relations among the anomalous parts of transport coefficients above and below the λ point are clarified. (auth)

58913 COLLOQUIUM ON HELIUM AT VERY LOW TEMPERATURES, GRENOBLE, FRANCE, MARCH 23–25, 1970. J. Phys. (Paris), Colloq.; C3: No. 10, C.1-136(Oct 1970). (In French and English). (CONF-700339).

The 12 papers which introduced the various round tables are presented. The four papers concerning superfluid helium are abstracted individually. (France)

For abstracts of individual papers see: 58914–58917.

58914 TRANSPORT PROPERTIES AND PHASE COHERENCE IN SUPERFLUID HELIUM. Libchaber, A. (Ecole Normale Superieure, Paris). J. Phys. (Paris), Colloq.; C3: No. 10, C.3.5-16(Oct 1970). (In French).

From Conference on helium at very low temperatures; Grenoble, France (23 Mar 1970). See CONF-700339.

Transport properties of superfluid He under critical and subcritical flow conditions are studied. Equations of motion for the superfluid are given from two models: the hydrodynamic model, and a model associated with order parameters. The crucial experiments on permanent currents are reviewed. Superleaks and transport in liquid helium films are studied. Experiments on the Josephson–Anderson effects are analyzed. (France)

58915 HYDRODYNAMICS AND SIZE EFFECTS IN SUPERFLUID HELIUM. Guyon, E. (Paris Univ., Orsay, France). J. Phys. (Paris), Colloq.; C3: No. 10, C.3.17-27(Oct 1970). (In French).

From Conference on helium at very low temperatures; Grenoble, France (23 Mar 1970). See CONF-700339.

Two-fluid hydrodynamics is used to study waves propagated in superfluid helium. The properties of first and second sound are briefly reviewed. The properties of fourth sound, which is a temperature and density wave, are discussed for porous systems in particular cases where the normal fluid is partially unlocked. Fourth and third sound, which are surface waves in the superfluid film, give information on size effects such as superfluid density and critical velocity. These results are compared with measurements. (France)

58916 SCATTERING OF LIGHT FROM LIQUID HELIUM. Vinen, W. F.; Vaughan, J. M. (Univ. of Birmingham, Eng.). J. Phys. (Paris), Colloq.; C3: No. 10, C.3.29-38(Oct 1970).

From Conference on helium at very low temperatures; Grenoble, France (23 Mar 1970). See CONF-700339.

A review is given of the scattering of light by superfluid helium. A brief discussion is given first of the theory of Brillouin and Rayleigh scattering from an ordinary simple pure liquid. It is shown how this discussion must be modified in the case of the superfluid phase of pure ^{4}He, and experimental observations of Brillouin scattering from first sound in liquid helium are described. The discussion is extended to the case of a superfluid mixture of ^{3}He and ^{4}He, and a recent observation of Brillouin scattering from second sound in such a mixture is described. Recent work on Raman scattering from superfluid helium (two-roton production) is then discussed, and in a final section a brief review is given of the special situation that obtains in the neighborhood of the λ point. (France)

58917 IONS AND VORTICES IN ^{4}He. Gamota, G. (Bell Telephone Labs., Murray Hill, N. J.). J. Phys. (Paris), Colloq.; C3: No. 10, C.3.39-54(Oct 1970).

From Conference on helium at very low temperatures; Grenoble, France (23 Mar 1970). See CONF-700339.

Experiments carried out to investigate the properties of ions in ^{4}He are reviewed and the results obtained discussed. Theoretical ideas on quantized vorticity and rotating helium are introduced and vortex rings discussed. The interaction of ions and vortices is considered and the processes linking the creation of vortex rings with the existence of a critical velocity and a new particle, designated the neutral, are investigated. (France)

58918 EXPLICIT EXAMPLES OF OFF-DIAGONAL LONG-RANGE ORDER. Di Castro, C.; Jona-Lasinio, G. (Univ., Rome. Istituto Nazionale di Fisica Nucleare, Rome). pp 91-100 of Methods and Problems of Theoretical Physics. /Bowcock, J. E. (ed.). New York; American Elsevier Publishing Co., Inc. (1970).

From Conference on methods and problems of theoretical physics; Birmingham, England (Jun 1967).

In attempting to construct a unified picture of the characteristic properties of superfluid He, the situation arises in which uncorrelated ideas of a different nature have to be invoked according to the particular problem under consideration. Those ideas which concentrate more on the thermodynamical properties and, therefore, deal mainly with macroscopic variables are considered and certain features are pointed out which, so far, have not received enough attention. (W.D.M.)

58919 HEAT CAPACITY OF LIQUID ^{4}He AND ^{3}He–^{4}He MIXTURES AT THE LAMBDA TRANSITION. Gasparini, Francis Marino. Minneapolis; Univ. of Minnesota (1970). 166p. University Microfilms Order No. 71-18,726.

Thesis.

The heat capacity of liquid ^{4}He and ^{3}He–^{4}He mixtures up to a ^{3}He concentration of 0.390 was measured with a temperature resolution of about 10^{-7}K. The measurements made with the partly filled calorimeter were shown to be equal to Cpx, the heat capacity of the liquid at constant pressure and concentration. Measurements of Cvx at two different molar volumes and $x \cong 0.30$ were also made. The data are analyzed in the context of scaling laws and the renormalization of critical exponents. (TSS) (Diss. Abstr. Int., B)

58920 COLLECTIVE MODES IN FERMI LIQUIDS. Clarke, John Stephen. Ithaca, N. Y.; Cornell Univ. (1970). 155p. University Microfilms Order No. 71-17,636.

Thesis.

As an application of the Landau theory of Fermi liquids, a simple expression for the relationship between momentum distribution parameters for any zero sound mode m, involving two parameters of the interaction A_m and A_{m+1}, was derived. The expression is

XUM

derived with the hypothesis that higher-order parameters are negligible. It can be shown from this expression, plus constraints imposed by the conservation of momentum and particles in collisions, that the m = 0 mode has very low attenuation compared to higher-order modes. Only the m = 0 mode has been observed in liquid ^{3}He, in the millidegree range of temperatures. Landau's theory, which assumes only short-range forces, has been extended by Silin to encompass the conduction electrons in a metal. This was done by introducing a self-consistent electric field. Collective oscillations due to Fermi-liquid interactions can occur in a metal, but the presence of electric fields alters the dispersion relation. As a result, such oscillations occur when the transverse conductivity is zero. It is shown that this can only occur in the presence of a strong magnetic field, because the electron–electron interaction is weak. With the assumption of specular electron reflection at the surfaces, simple expressions can be derived for the optical constants of a parallel plane metal slab. The dynamics of electron motion are represented exclusively by the conductivity. Fermi liquid corrections do not significantly alter the reflectivity or surface impedance in this model, but transmissivity is significantly enhanced in a narrow region of frequency near the cyclotron frequency, ω_c. (TSS) (Diss. Abstr. Int., B)

58921 CRITICAL VELOCITIES IN SUPERFLUID HELIUM FLOW THROUGH 10-μm-DIAMETER PINHOLES. Hess, George B. (Univ. of Virginia, Charlottesville). Phys. Rev. Lett.; 27: No. 15, 977-9(11 Oct 1971).

The dissipation mechanism that usually limits superfluid flow to about 30 cm/sec in large pinholes is found to be suppressed by compressed-rouge superfluid filters placed in the flow path on each side of the orifice. The much larger intrinsic critical velocity is then observed for the first time in large channels. (auth)

58922 DEPENDENCE OF THE HELIUM II FILM TRANSFER RATE ON PRESSURE HEAD, FILM HEIGHT, AND SUBSTRATE. Duthler, Carl James. East Lansing, Mich.; Michigan State Univ. (1970). 90p. University Microfilms Order No. 71-18,196. Thesis.

Helium film transfer rates, σ, were measured as a function of level difference, z, and height, h to the beaker rim, for filling clean glass and neon coated beakers. Measured transfer rates as a function of level difference or pressure head are described by: $\sigma(z) = 1/[A - B(\ln z(\mathrm{cm}))]$. For T = 1.65 K and h = 7 cm, the values $A = (1.80 \pm 0.09) \times 10^4$ sec/cm^2 and $B = (8.9 \pm 1.9) \times 10^2$ sec/cm^2 are found. For T = 1.28 K and h = 7 cm, the values $A = (1.35 \pm 0.02) \times 10^4$ sec/cm^2 and $B = (8.4 \pm 1.4) \times 10^2$ sec/cm^2 are found. The dependence of the transfer rate on height is: $\sigma(h) = 10(\rho_s/\rho)h^{-(0.26\pm0.05)} \times 10^5$ cm^3/sec-cm. These observations give the dependence, $P_s \propto \exp[f(h,T)/v_s]$, of the frictional pressure, P_s which opposes the flow, on superfluid velocity, v_s. The dependence, $v_c \propto d^{-1/4}$, of the critical velocity, v_c, on film thickness, d, is also determined from these results. A 16% decrease is observed in σ going from a clean glass substrate to a neon coated substrate in the same apparatus. This result is in reasonable agreement with the calculated helium film thickness for a neon substrate of $2.3h^{-1/3} \times 10^{-6}$ cm. (Diss. Abstr. Int., B)

58923 CORE STRUCTURE OF A QUANTIZED VORTEX. Fetter, Alexander L. (Stanford Univ., Calif.). Phys. Rev. Lett.; 27: No. 15, 986-8(11 Oct 1971).

The core of a singly quantized vortex is shown to consist of both condensed and noncondensed particles. Model calculations with an imperfect Bose gas suggest a plausible core structure in liquid helium. (auth)

58924 SUM RULES FOR A BINARY SOLUTION OF EFFECTIVE INTERACTIONS BETWEEN ^{3}He QUASI PARTICLES IN SUPERFLUID ^{4}He. Tan, Hing-tat (Univ. of Minnesota, Minneapolis); Woo, Chia-wei; Wu, F. Y. Contract AT(11-1)-1569. J. Low Temp. Phys.; 5: No. 3, 261-5(Sep 1971).

Sum rules are derived for dynamic structure factors for a binary solution and applied to the Woo–Tan–Massey theory of ^{3}He–^{4}He solutions. It is demonstrated that in the long-wavelength region the effective ^{3}He quasi-particle interaction V_k contains no linear k dependence. In other words, $V_k \rightarrow A + Bk^2$, as $k \rightarrow 0$. This result is exact, and requires no empirical information. It is consistent with expressions of V_k assumed by Eckstein, Eckstein, Kuper, and Ron, and by Ebner, based on fitting experimental data such as osmotic pressure measurements. (auth)

58925 POTENTIAL-PROBE DISSIPATION MEASUREMENTS IN A FLOWING SUPERFLUID HELIUM FILM. Liebenberg, D. H. (Los Alamos Scientific Lab., N. Mex.). J. Low Temp. Phys.; 5: No. 3, 267-73(Sep 1971).

Dissipation along a thermally driven, flowing, superfluid helium film was measured using an adaptation of the Keller–Hammel potential probes. These data are described by Langer–Fisher fluctuation theory, provided the velocity dependence is characteristic of vortex ring generation. (auth)

58926 MASS AND SPIN DIFFUSION NEAR THE λ LINE IN DILUTE ^{3}He–^{4}He MIXTURES. Eggington, M. A.; Leggett, A. J. (Univ. of Sussex, Brighton, Eng.). J. Low Temp. Phys.; 5: No. 3, 275-84(Sep 1971).

The possibility of using NMR and other measurements on very weak solutions of ^{3}He in liquid ^{4}He to investigate the superfluid phase transition is examined. It is found that even for these very weak solutions the mass (D_m) and spin (D_s) diffusion coefficients associated with the ^{3}He behave in radically different ways: D_m is predicted to diverge as T approaches T_λ from above as $(T - T_\lambda)^{-1/3}$, while the behavior of D_s depends on the type of experiment, and for the ordinary spin–echo type, has no particular singularity. (auth)

58927 FLOW DISSIPATION EQUATION IN LIQUID HELIUM II. Chester, Marvin; Ziff, Robert (Univ. of California, Los Angeles). J. Low Temp. Phys.; 5: No. 3, 285-311(Sep 1971).

At high flow rates superfluid helium exhibits dissipation in that a chemical potential gradient is necessary to drive the flow. On the basis of a specific model for the cause of this behavior, a detailed relationship between the chemical potential gradient and the resultant flow is derived. Some implications of the theory with regard to recent experiments are discussed. (auth)

Superconductivity

58928 (CALT-822-37) OCCURRENCE OF SUPERCONDUCTIVITY IN SIMPLE CUBIC $(Au_{1-x}Pd_x)Te_2$ ALLOYS. Chen, Wilkie Y. K.; Tsuei, C. C. (California Inst. of Tech., Pasadena. W. M. Keck Lab. of Engineering Materials). Oct 1971. Contract AT(04-3)-822. 9p. Dep. NTIS.

The superconducting transition temperatures and lattice parameters of metastable simple cubic alloys $(Au_{1-x}Pd_x)Te_2$, with $0 \leq x \leq 0.6$, obtained by rapid quenching from liquid state, were measured as a function of x. As x increases, the transition temperature T_C goes through a minimum of 1.6°K near x = 0.05 and then increases steadily to a maximum of 4.5°K at x = 0.45. The lattice parameter shows a slight linear decrease as x increases. Transverse magnetoresistance for the composition x = 0.2 saturates at relatively low field (~2 kG) and is unusually large (~0.14). The initial depression of T_C with increasing Pd content can be interpreted in terms of the information obtained in a previous study of binary Au–Te alloys. The unusual increase of T_C with further increase in Pd concentration is not well understood. (auth)

58929 (FRNC-TH-72) MEASUREMENT DEVICE AND NUMERICAL ANALYSIS OF ELECTRICAL RESISTIVITY FROM 4 TO 300°K. APPLICATION TO NIOBIUM–HAFNIUM ALLOYS. Teixeira, J. M. (Grenoble Univ. (France). Faculte des Sciences). 1970. 116p. (In French). Dep. NTIS (U. S. Sales Only). Thesis.

Niobium–hafnium alloys were studied from the point of view of superconductivity by making measurements at different temperatures. In this way an apparatus was developed, which uses only one cryogenic liquid and is capable of measurements between 4 and 300°K. Measurements made on a great number of samples with different concentrations and heat treatments allowed the critical temperatures and changes in parameters of the Bloch–Wilson theory to be determined. Identical resistivity laws were obtained for the strain-hardened or annealed Nb–Hf samples. (France)

58930 HIGHER ORDER EFFECTS DUE TO SUPERCONDUCTING FLUCTUATION ON ELECTRICAL CONDUCTIVITY. Takayama, Hajime (Tokyo Univ.); Maki, Kazumi. Progr. Theor. Phys. (Kyoto); 46: No. 1, 42-62(Jul 1971).

Higher-order corrections to electrical conductivity due to the fluctuation of the superconducting order parameter in the paraconducting region are studied systematically. Use is made of a perturbation expansion in powers of independent fluctuations. When $\delta \gg \epsilon_0$, where δ is a pair-breaking energy and $\epsilon_0 (= (8/\pi)(T - T_c))$ is the relaxation rate of the order parameter, it is shown that the deviation from the mean field theory can be described by use of the renormalized fluctuation propagator, consistent with the idea of the dynamical scaling theory. When $\delta \ll \epsilon_0$, on the other hand, the conductivity diverges more strongly than that expected from the analysis of the static properties and, in this case, the above idea appears not to be applicable. In particular, the most divergent series are summed up for small δ, and it is shown that the anomalous term still diverges but with a weaker δ^{-1} dependence. Fluctuation effects on other transport coefficients are also studied. (auth)

58931 SURFACE SECOND SOUND IN LIQUID HELIUM. Andreev, A. F.; Kompaneets, D. A. (Inst. of Physics Problems, Moscow). JETP Lett. (USSR) (Engl. Transl.); 13: No. 12, 511-14(20 Jun 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 13: No. 12, 720-4(20 Jun 1971).

Capillary waves can propagate over the surface of liquid helium, and in the superfluid solution ^{3}He in ^{4}He, there exist also surface impurity levels. Both can be regarded as surface elementary excitations. Their motion is accompanied by transport of mass, energy, entropy, etc., and it can be regarded as a motion of a surface normal component. The surface normal density is calculated in analogy with the volume case, and by substituting in the equation obtained the spectrum of capillary waves and the Planck function, the surface normal density of pure ^{4}He is obtained. It is noted that the spectrum of the capillary waves does not satisfy the Landau superfluidity criterion. If, however, the finite nature of the force of gravity is taken into consideration, then the critical velocity turns out to be finite. The oscillations of a plane free surface are considered, with allowance for the surface normal component. The system of equations describes two types of oscillations. Oscillations of the first type are ordinary capillary waves. Oscillations of the second type are analogous to volume second sound and are called surface second sound. (M.H.R.)

58932 ELECTRON DECELERATION BY DISLOCATIONS IN TYPE-II SUPERCONDUCTORS. Pustovalov, V. V.; Startsev, V. I.; Fomenko, V. S. (Physical-Technical Inst. of Low Temperatures, Kharkov). Dokl. Akad. Nauk SSSR; 196: No. 6, 1313-15(21 Feb 1971). (In Russian).

The effects of the superconducting-to-normal transition (s-n), the mixed state (s-m), and the reverse transitions (n-s and m-s) on the deforming voltage were studied in Type-II superconductors in comparison with those of Type-I (Pb, In, Tl, Sn, Hg). Tests were conducted on Pb−In alloys prepared from 99.999% pure Pb and In. Polycrystalline samples were deformed by voltage at low temperatures. The In−3.9 at. % Pb alloy, in particular, was useful in the determination of magnetization curves and thermal conductivity because this alloy exhibits Type-I superconductivity at $T > 2.25°K$, and Type II at $T < 2.25°K$. The deforming voltage behavior was a feature that differentiated Type-I and Type-II superconductors. (K.S.W.)

58933 ANOMALOUS BEHAVIOR OF THE SUPERCONDUCTING TRANSITION TEMPERATURE OF LEAD WITH A DISTORTED CRYSTAL LATTICE. Lazarev, B. G.; Semenenko, E. E.; Tutov, V. I. (Physical-Technical Inst., Kharkov). Dokl. Akad. Nauk SSSR; 196: No. 6, 1329-30(21 Feb 1971). (In Russian).

The superconducting transition temperature is generally raised by the presence of a deformed metal lattice, with a concomitant broadening of the interval of transition. Condensation of the vapor from molten lead upon a surface chilled in liquid helium provided a deformed crystalline lattice of lead in the form of a film of any desired thickness. The results of superconductivity measurement showed that a thick lead film (2,000 Å) exhibited an insignificantly small displacement of the transition temperature. In contrast, a thin (50 Å) lead film exhibited a 10% shift in the absolute temperature of transition (6.4°K instead of the 7.2°K characteristic of massive lead). Studies were made on thicknesses between the above values, and a brief discussion of their corresponding resistances is included. (K.S.W.)

58934 HIGH-TEMPERATURE SUPERCONDUCTIVITY. Ginzburg, V. L.; Kirzhnits, D. A. Vestn. Akad. Nauk SSSR; No. 5, 78-85(May 1971). (In Russian).

Advances in superconductivity from 1911 (its discovery) to the present are reviewed. With the advent of time, materials with higher critical temperatures are being discovered; thus it is predicted that T_c's of 20 to 25°C should be known within the next 20 years. Three avenues are open for search for exciton (high temperature) superconductors: metals or nonmetals (with a small number of conducting electrons), organic or polymer materials (quasi-one-dimensional chains), and plane systems (sandwich and layer compounds, quasi-two-dimensional networks). The latter is illustrated by alternate layers of TaS_2 and pyridine molecules. (K.S.W.)

58935 NON-MAGNETIC RESONANCE SCATTERING IN TWO-BAND SUPERCONDUCTORS. Kusakabe, Takashi (Tokyo Univ. of Education). Progr. Theor. Phys. (Kyoto); 45: No. 5, 1376-81(May 1971).

The Anderson model extended to two overlapping bands is used to investigate the effect of ferromagnetic transition-metal impurities on superconductors of some transition metals due to nonmagnetic resonance scattering. The initial change in the superconducting critical temperature T_c is calculated. The results are very similar to those obtained in a previous paper, i.e., T_c is found to increase linearly with the impurity concentration for $\alpha > 1$ and, of course, to decrease linearly with the concentration for $\alpha < 1$; α is a certain parameter given by a previous paper. However, one may expect that nonmagnetic resonance scattering has a remarkably large effect as in the one-band model. The correlation effect among the localized electrons is found to be very small in comparison with the influence of nonmagnetic resonance scattering in contrast to expectations in the one-band model. Finally, it may be said that the influence of the nonmagnetic impurity scattering is very important because it reflects the more precise nature of superconductivity of some transition metals. (auth)

58936 SUPERCONDUCTING FLUCTUATION EFFECTS ON THE S-I-N JUNCTION CURRENT. Takayama, Hajime (Tokyo Univ.). Progr. Theor. Phys. (Kyoto); 46: No. 1, 1-14(Jul 1971).

A microscopic study of superconducting fluctuation effects is applied to the investigation of various tunneling currents through an $M_1/I/M_2$ junction in which the temperature is just above the transition temperature T_c of the metallic film M_2, and is well below that of the metal M_1. The main contribution to the current in the voltage region $eV \simeq T - T_c \ll T_c$ comes from the tunneling of Cooper pairs, existing temporarily in M_2 due to fluctuation. It is found out that this current exhibits a qualitatively different behavior according to the condition whether the transmission of particles through a barrier is specular or diffuse. If it is assumed to be specular, the behavior of the current agrees qualitatively with Ferrell's and Scalapino's results obtained by semi-phenomenological discussions for the fluctuations. (auth)

58937 NATURE OF ANOMALIES IN RESISTIVE STATE OF A SUPERCONDUCTOR. Smirnov, A. P.; Fedorov, N. F. (Ioffe Inst. of Physics and Tech., Leningrad). Sov. Phys.-Solid State (Engl. Transl.); 13: No. 3, 657-9(Sep 1971).

Translated from Fiz. Tverd. Tela; 13: No. 3, 796-8(Mar 1971).

Resistivity anomalies are examined for current-induced superconductivity loss in films of indium and tin. The potential difference varies nonmonotonically with current on account of bubble boiling of the helium, which also causes antihysteresis and resistance oscillations at constant current. The effects also involve heat transfer to the liquid in the boiling turbulent flow near the surface of the specimen. The anomalies vanish when gaseous helium is used. The role of heat effects is discussed for certain anomalies observed in other solid-state experiments with liquid helium and other liquids. (auth)

58938 IMPEDANCE MATCHING A JOSEPHSON GALVANOMETER BY MEANS OF A SUPERCONDUCTING TRANSFORMER. Clarke, John; Tennant, William E.; Woody, D. (Univ. of California, Berkeley). J. Appl. Phys.; 42: No. 10, 3859-65(Sep 1971).

The concept of an effective noise temperature is developed and applied to superconducting galvanometers. It is shown that even when the device is being used at a temperature above its noise temperature, Johnson noise in a source resistance may be observed only if this resistance is below a certain value, defined as the critical resistance. A detailed design is given for a superconducting transformer that matches the galvanometer to higher resistance and thereby appreciably increases the critical resistance. The transformer may be used at zero frequency. A practical transformer is described that has been used with the Josephson device known as the Slug. The transformer increased the critical resistance from 7×10^{-8} to 2×10^{-2} Ω and could be readily adapted to match to resistances up to 1 Ω. (auth)

58939 ROLE OF SPIN–ORBIT SCATTERING IN HIGH-FIELD SUPERCONDUCTING TUNNELING. Engler, Hans (Univ., Frankfurt am Main); Fulde, Peter. Z. Phys.; 247: No. 1, 1-8(1971).

The observation of the magnetic field splitting of the quasiparticle states in thin superconducting films does make it possible to determine the size of spin−orbit interactions via tunneling experiments. The tunneling density of states of such films in the presence of spin−orbit interactions is calculated and it is demonstrated that the tunneling conductance between two films of identical material in a parallel field should be an especially sensitive function of spin−orbit scattering. Numerical results for the tunneling density of states as well as for the tunneling conductance as function of spin−orbit scattering rate are presented. (auth)

58940 EFFECTS OF BISMUTH IMPURITY UPON THE CRITICAL FIELD CURVE OF SUPERCONDUCTING TIN. Green,

XUM

Clarence Rufus. Clemson, S. C.; Clemson Univ. (1970). 88p. University Microfilms Order No. 71-17,405.

Thesis.

Approximately 40 cylindrically shaped quasi-single-crystal samples of tin doped with up to 1 at. % of bismuth impurity were prepared. The samples were 2 mm in diameter and were approximately 6 cm long. Measurements of the electrical resistivity of the samples were made at room temperature and at 4.2K to determine the residual resistivity ratio, which relates to a theoretical parameter in the theory of Markowitz and Kadanoff and in the theory of Clem. A technique for detecting the transition between the superconducting and normal phases was developed that reflected the change in magnetic susceptibility of the sample that occurs with the transition. The critical temperature was determined by linear extrapolation of the critical field to zero applied field; the critical field at absolute zero was obtained by extrapolation of H_c vs. t^2 to zero temperature. The slope of the critical field curve $(dH_c/dT_c)T_c$ was obtained from a least-squares fit of the critical field data near T_c to a straight line. The depression of T_c with addition of bismuth impurity is compared to and found to be in good agreement with the theory of Markowitz and Kadanoff and with the experimental data of Lynton, Serin and Zucker. The reduced slope of T_c for pure tin was found to lie between the values predicted by Clem and by BCS, differing from the value of Clem by about 3.5% and from the BCS value by about 1.1%. The theory of Clem predicts that the ratio H_0/T_c and the slope $(dH_c/dT)T_c$ should increase with doping to maximum deviations of 1.6% and 3% from the values for pure tin over the range of impurity concentrations used here. This work finds, however, that these quantities vary in the opposite sense from Clem's prediction, i.e., both H_0/T_c and $(dH_c/dT)T_c$ are observed to decrease initially with doping to maximum deviations of 7% and 5.5% from the corresponding values for pure tin. The reason for the discrepancy between theory and experiment is not understood. (TSS) (Diss. Abstr. Int., B)

58941 CRITICAL FIELD OF A SOLID CYLINDER WITH A COATING OF NORMAL METAL. Khamidullin, M. G. Fiz. Metal. Metalloved.; 31: No. 1, 30-6(Jan 1971). (In Russian).

Using the general macroscopic theory of superconductivity, the critical magnetic field of a solid superconducting cylinder covered with a thin film of normal metal is considered theoretically. An exact method of calculating the critical field as a function of the radius of the cylinder and the parameters of the associated magnetic system is presented. In the case in question the critical field is lower than that of a solid superconducting cylinder without a coating of normal metal; in other words, the superconductivity is partly suppressed by the coating. The critical field is an oscillatory function of the cylinder radius. (Metals Abstr.)

58942 ELECTRON MICROSCOPE INVESTIGATION OF THE STRUCTURE OF SUPERCONDUCTING ALLOY Ti–22 AT. PERCENT Nb. Vozilkin, V. A.; Buinov, N. N.; Bychkov, Yu. F.; (and others) (Inst. of Physics of Metals, Moscow. Lebedev Inst. of Physics, Moscow). Fiz. Metal. Metalloved.; 30: No. 4, 753-61(Oct 1970). (In Russian).

The structure of a superconducting Ti–22 at. % Nb alloy was studied by electron microscopy after various forms of heat treatment; the type of heat treatment leading to the appearance of ω- and α-phase precipitates was determined. Water-quenching from 800°C yielded ω-phase precipitates, the dimensions of which increased with increasing ageing temperature. Ageing above 450°C also yielded a high proportion of α-phase. The formation of ω- and α-phase precipitates 400 Å in dia was responsible for the high values of critical current density (2×10^{-3} A/cm^2) observed in some of the samples. (Metals Abstr.)

58943 DIRECT OBSERVATION OF SPIN-STATE MIXING IN SUPERCONDUCTORS. Tedrow, P. M.; Meservey, R. (Massachusetts Inst. of Tech., Cambridge). Phys. Rev. Lett.; 27: No. 14, 919-21(4 Oct 1971).

A peak in the tunneling conductance was observed between two very thin superconducting aluminum films in an intense parallel magnetic field at a voltage $V = (\Delta_1 + \Delta_2 - 2\mu H)/e$. The magnetic field dependence of this peak identifies it as that predicted by Engler and Fulde for spin-state mixing in superconductors. The spin–orbit scattering rate $b = \hbar/3\Delta\tau_{S.O.}$ obtained from this measurement is approximately 0.1. (auth)

58944 SUPERCONDUCTIVITY OF GALLIUM ARSENIDE AT HIGH PRESSURES. Berman, I. V.; Brandt, N. B.; Sidorov, V. I. (Moscow State Univ.). JETP Lett. (USSR) (Engl. Transl.); 14: No. 1, 11-12(5 Jul 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 1, 18-19(5 Jul 1971).

Superconductivity was observed in GaAs at pressures exceeding 250 kbar. In the pressure region 250 to 300 kbar, the resistance of the samples upon cooling from 240 to 5°K decreased by approximately 4 times. With further lowering of the temperature, sharply pronounced transitions to the superconducting state were observed. The temperature T_c of the transition into the superconducting state was 4.8°K at p = 260 kbar and decreased with further increase of pressure in the interval 260 to 300 kbar, at an average rate $dT_c/dp = 0.2 \times 10^{-5}$ deg/bar. (M.H.R.)

58945 DYNAMICAL FLUCTUATION OF THE ORDER PARAMETER AND DIAMAGNETISM OF SUPERCONDUCTORS. I. DIRTY LIMIT. Maki, Kazumi (Tohoku Univ., Sendai); Takayama, Hajime. J. Low Temp. Phys.; 5: No. 3, 313-23(Sep 1971).

Limiting attention to dirty superconductors, the fluctuation-induced diamagnetism above the superconducting transition is studied theoretically. It is found that the dynamical fluctuation is extremely important except in the immediate vicinity of the transition region [i.e., $T \cong T_c(H)$ or $H \cong H_{c2}(T)$, where H_{c2} is the upper critical field] and that this contribution does account for a large discrepancy between previous calculations and the recent experiment by Gollub, Beasley, and Tinkham. (auth)

58946 RESISTIVE BEHAVIOR OF THE SUPERCONDUCTING SURFACE SHEATH OF ALLOYS. Monceau, P.; Gilchrist, J. le G. (CNRS, Grenoble, France). J. Low Temp. Phys.; 5: No. 3, 363-75(Sep 1971).

Measurements are reported of the surface resistance of dirty Type-II superconductors driven into the surface-sheath regime by a static magnetic field, H_0, parallel or nearly parallel to the sample surfaces and transverse to the microwave current, in which condition the latter can excite fluctuations of the order parameter. A recent calculation by Maki has suggested that the surface resistance would be influenced by the presence of Kulik's vortex state even when the sample surface is polished and is as nearly as possible parallel to H_0. It is therefore proposed that the sample surface should be decomposed into elements that make different angles with HO, and the distribution of these angles described by a Gaussian, $\kappa_2(t)$, is deduced from the surface-resistance measurements near H_{c3}, so interpreted, and a temperature variation, $\kappa_2(t)/\kappa_2(l)$, is found that agrees reasonably with theory and with magnetization data, $[\kappa_2(l) \neq \lim_{t\to 1}(\kappa_2)]$. It is suggested that the anomalously large variation of $\kappa_2(t)$ reported by Fischer and Maki may have resulted from failure to take Kulik's vortices into account. In magnitude, present $\kappa_2(l)$ data agree with theory but not with magnetization data. (auth)

58947 PERIODIC MODES AND STRUCTURAL TRANSITION IN THE LABBE–FRIEDEL MODEL OF A_3B COMPOUNDS. Barisic, S. (Faculte des Sciences, Orsay, France). Solid State Commun.; 9: No. 17, 1507-12(1 Sep 1971).

The Labbe–Friedel model is applied to the computation of the phonon self-energy in A_3B compounds. It is shown that the linearized theory of the long-wavelength instability corresponds to the linearized Labbe–Friedel theory of the homogeneous deformation. The introduction of periodic modes does not change the first order of this transition, determined by higher-order energy terms. In the most interesting range or parameters the homogeneous deformation occurs at a temperature higher than the Kohn instability. The growth of the tetragonal phase stabilizes to some extent the Kohn mode in Nb_3Sn and the superconducting transition occurs for temperatures considerably higher than the critical temperature for the Kohn instability. (auth) (UK)

58948 SUPERCONDUCTING ALLOYS OF THE Nb–Al–Ge SYSTEM. Kalinin, G. P.; Vaulinskii, E. S.; Elyutin, O. P.; (and others). Metal Sci. Heat Treat. (USSR) (Engl. Transl.); No. 7-8, 676-8(Jul-Aug 1970).

Translated from Metalloved. Term. Obrab. Metal.; No. 8, 44-7(Aug 1970).

The properties of Nb–Al–Ge alloys in the pseudobinary Nb_3Al–Nb_3Ge section were investigated in order to obtain alloys with the highest superconducting transition temperature. On the diagram of composition vs. superconducting transition temperature for alloys of the Nb–Ge–Al system, there is a region of alloys with $T_c > 16$°K. This region is bounded by alloys with 75 to 76 at.% (89.6 to 91.6 wt.%) Nb, 3 to 5 at.% (2.8 to 4.5 wt.%) Ge, and the rest aluminum. To obtain high values of T_c it is necessary that the ratio of niobium to the total concentration of aluminum + germanium be strictly controlled (75 to 76 : 24 to 25). (TSS)

58949 EQUIVALENCE OF THE SUPERCONDUCTING TRANSITION TEMPERATURE OF PURE INDIUM AS DETERMINED BY ELECTRICAL RESISTANCE, MAGNETIC SUSCEPTIBILITY, AND HEAT-CAPACITY MEASUREMENTS. Soulen, Robert J. Jr.; Colwell, Jack H. (National Bureau of Standards, Washington, D. C.). J. Low Temp. Phys.; 5: No. 3, 325-33(Sep 1971).

The superconducting transition temperature of a well-annealed polycrystalline sample of pure indium was determined by three different techniques. The heat-capacity and susceptibility transitions are approximately 1 mK wide and span the same temperature interval. The resistance transition is less than 0.2 mK wide and occurs at the center of the other transitions. By choosing the midpoint of each transition the three measurements are identical to within 0.1 mK. (auth)

58950 ELECTRICAL BREAKDOWN OF COLD GASEOUS HELIUM. Meats, R. J. (Central Electricity Research Labs., Leatherhead, Eng.). pp 48-52 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

Although a poor insulant for most practical purposes, He gas is a potential component of insulating systems for superconducting power devices, and at the very low temperatures relevant to superconductivity its density is about 15 kg/m^3 compared with 0.17 kg/m^3 at room temperature, leading to a considerable increase in its electrical breakdown field. An investigation of the uniform field direct-voltage breakdown characteristics of He was carried out from 4.2 to 10 K, covering the temperature range for superconductive power applications. Results indicated that He is very suitable as a dielectric for superconducting power cables and similar devices. (UK)

Equipment and Devices

58951 SUPERCONDUCTIVE COMPOSITES. Maddock, B. J. Composites; 1: No. 2, 104-11(Dec 1969).

Ordinary conductors are generally used in composites with superconductors to control resistance and temperature increases. Conductors based on Nb–Ti superconductors are formed by cladding with Cu and then processing by standard techniques such as forging, swaging, extrusion or rolling. Conductors of Nb–Ti, which must be adiabatically stable, can be produced by twisting the filaments in a Cu matrix or by using a matrix of a Cu–Ni alloy. The more brittle Nb_3Sn superconductors are produced as thin layers on a Cu or stainless steel substrate by either vapor deposition or a diffusion process. Current and potential applications for the composites include electromagnets, electrical-power transmission cables, pulse-energy storage devices, and prototype MHD generators. (Metals Abstr.)

58952 NONISOTHERMAL SUPERCONDUCTING BOLOMETER. II. Konovodchenko, V. A.; Dmitriev, V. M.; Komarevskii, S. K.; Loktionov, N. F. Sb. Nauch. Tr., Fiz.-Tekh. Inst. Nizk. Temp., Akad. Nauk Ukr. SSR; No. 9, 72-84(1970). (In Russian).

The most general stationary problem of thermal conductivity of nonisothermal superconducting bolometers is studied, and a method of graphoanalytical investigation of its characteristics is developed. A system of equations for determining the current coordinates of the boundaries of the sections of the superconducting bolometer with different states of the superconductor was obtained as a result of solving this problem. A number of special cases of solving the system are investigated, which along with having independent value, also turn out to be very useful when writing and developing the program for its complete solution. (TSS) (JPRS)

58953 ELECTRICAL CONDUCTORS INCLUDING SUPERCONDUCTOR MATERIAL. (to Siemens Aktiengesellschaft). British Patent 1,247,832. 29 Sep 1971. Priority date 25 Jun 1969, Germany.

An electrical conductor is described that is comprised by a tube, for carrying coolant, and a strip-form conductive assembly extending alongside the tube and fixed flat against a lateral external face. The strip-form conductive assembly is comprised by wires of superconductor material embedded in normally electrically conducting metal at an operating temperature at which the superconductor material is in its superconducting state. These wires extend along the strip-form assembly but are twisted about a longitudinal axis of the assembly. The tube is made of metal that is normally electrically conductive at the operating temperature. (M.H.R.)

58954 SUPERCONDUCTING CONDUCTOR. Royet, Jean (to Compagnie Generale d'Electricite). British Patent 1,247,260. 22 Sep 1971. Filed 24 Dec 1969.

The conductor described is comprised of a wire or strip of superconducting material located within a tube made of a material having, at normal temperatures, an electrical conductivity of the order of that of Al. The superconductivity material may be parallel to, or extend helically around, the axis of the tube. A sheathing envelops the tube, in good thermal and electrical contact therewith; this sheathing consists preferably of Al alloy, applied around the tube by an extrusion method. (UK)

Plasma and Thermonuclear Physics

58955 TECHNOLOGY INDEX FOR PLASMAPHYSICS RESEARCH AND FUSION REACTORS. VOLUME 5, NO. 7, 1971. Frankfurt am Main; Zentralstelle fuer Atomkernenergie-Dokumentation (1971). 45p.

This listing includes 217 references on various aspects of controlled thermonuclear research. (M.O.W.)

58956 GLOBAL TEMPERATURE EFFECTS OF THE USE OF FUSION ENERGY AND THE FUSION TORCH. Porter, W. A.; Hagler, M. O.; Kristiansen, M. (Texas Tech. Univ., Lubbock). IEEE (Inst. Elec. Electron. Eng.), Trans. Nucl. Sci.; NS-18: No. 1, 31-6(Feb 1971).

From IEEE nuclear science symposium; New York, N. Y. (4 Nov 1970).

Per capita energy requirements for the world are projected for 2000 AD and 2020 AD. The release of this energy will cause the surface temperature of the earth to rise. This places a limit on world population in terms of standard of living and increase in surface temperature. (auth)

58957 FIZIKA PLAZMY I PROBLEMY UPRAVLYAEMOGO TERMOYADERNOGO SINTEZA. VYPUSK I. (Plasma Physics and Problems of Controlled Thermonuclear Synthesis. Number 1). Eight Annual Conference Held at Kharkov, May 20–28, 1968. Tolok, V. T. (ed.). Kiev; Naukova Dumka (1971). 304p. (CONF-680565).

This collection of 35 papers was presented at the Eighth Annual Conference on Plasma Physics and Problems of Controlled Thermonuclear Synthesis held May 20 to 28, 1968, at Khar'kov in Russia. The results of experimental and theoretical investigations of the high-frequency properties of a gaseous discharge plasma are discussed. Nearly half of the papers are concerned with the interaction of beams of charged particles with a plasma. Fewer papers are devoted to gaseous discharge and problems of instability. (K.S.W.)

Confinement and Heating

58958 (CEA-CONF-1807) PLASMA CONFINEMENT IN THE DECA II B CIRCULARIZED MAGNETIC WELL. Launodis, D.; Lecoustey, P.; Nicolas, M.; Tachon, J.; Kesner, J. (Commissariat a l'Energie Atomique, Saclay (France). Centre d'Etudes Nucleaires). 1971. 3p. (In French). (CONF-710527-8). Dep. NTIS (U. S. Sales Only).

From Physics conference; Evian, France (25 May 1971).

The plasma equilibrium is stable against flutes in spite of the shallow well of DECA II B. The ionic distribution function is minimum for a given angle at the beginning of the confinement. It changes during 600 μsec to reach a maximum for the same value of this angle. The causes of this change are discussed. (France)

58959 (CEA-CONF-1830) PARAMETER STUDY FOR A TRANSIT TIME MAGNETIC PUMPING EXPERIMENT IN A TORUS. Brambilla, M.; Giuffre, S. (Commissariat a l'Energie Atomique, Grenoble (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-1). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

Transit-time magnetic pumping is a slow process and must be performed in a machine already having good performances. It is shown that a T.T.M.P. experiment is possible in a Stellarator or a Tokamak having the same size as the existing devices. (France)

58960 (CEA-CONF-1831) PLASMA HEATING AT THE LOWER-HYBRID RESONANCE. Capitain, J. J.; Ichtchenko, G.; Lallia, P.; Moulin, D.; Nguyen, T. K.; Pesic, S. S. (Commissariat a l'Energie Atomique, Grenoble (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-4). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

In order to investigate the efficiency of noncollisional absorption mechanisms at high frequencies, an experimental study of the lower hybrid heating of a dense laser-produced plasma was made. The lower hybrid resonance occurred when the electron density was $2 \times 10^{14}/cm^3$. The absorption of a small part of the incident

XUM

power must be sufficient to make the collisionless contribution to the heating lower than the collisional one. (France)

58961 (CONF-711016–1) CONTAINMENT IN TOKAMAK AND BUMPY TORUS. Dory, R. A.; Guest, G. E.; Harris, E. G.; Hogan, J. T.; Widner, M. M. (Oak Ridge National Lab., Tenn.). [nd]. 4p. Dep. NTIS.

From Conference on plasma theory; Kiev, USSR (19 Oct 1971).

The energy flow and current diffusion in tokamaks were studied theoretically. It is concluded that tokamak confinement can lead to thermonuclear regimes if optimistic scaling laws hold true. A brief discussion on the bumpy torus concept is also given. (M.O.W.)

58962 (IPP-IV–25) SIMPLE LOW-LOSS COUPLING METHOD FOR RF HEATING OF PLASMA IONS BY ELECTROSTATIC ION-CYCLOTRON WAVES. Puri, S.; Tutter, M. (Institut fuer Plasmaphysik, G.m.b.H., Garching (West Germany)). Aug 1971. 11p. Dep. NTIS (U. S. Sales Only).

It is proposed to excite TEM waves in a cylindrical coaxial waveguide consisting of a metallic outer conductor with the plasma acting as the inner conductor. It is found that for frequencies of the order of the ion gyrofrequency, the penetration depth of the TEM wave fields into the plasma generally exceeds the wavelength of the electrostatic ion-cyclotron waves. The electrostatic ion-cyclotron waves thus excited propagate radially into the plasma and are collisionally absorbed if the time of energy propagation (at the wave's group velocity) over a distance of plasma diameter is of the order of or greater than the energy equipartition time due to ion–ion collisions. Numerical calculations for some representative examples indicate that this method could be used to heat plasma ions with a rather high efficiency. (auth)

58963 EXPERIMENT ON THE OHMIC HEATING OF PLASMA IN THE HELIOTRON C MAGNETIC FIELD. I. EQUILIBRIUM. Oshiyama, Hiroshi; Mohri, Akihiro; Ariga, Seiich; (and others) (Kyoto Univ.). J. Phys. Soc. Jap.: 31: No. 4, 1213-20(Oct 1971).

The equilibrium of the current-carrying toroidal plasma in the Heliotron C field is studied experimentally. The equilibrium state is very sensitive to a change in the transverse field of order 10^{-3} of the main confining field. The effect of a vertical magnetic field on the equilibrium is precisely examined by measuring the electrostatic equipotential surface of the plasma and the apparent electric conductivity of the plasma current. The observed values of the optimum vertical field B_v, which is necessary for the equilibrium of a current-carrying toroidal plasma, are about $\frac{1}{2}$ to $\frac{1}{3}$ of the theoretical values. (auth)

58964 ADIABATIC COMPRESSION OF PLASMA IN TRAPPED-PARTICLE-FREE STELLARATOR. Ikuta, Kazunari (Nagoya Univ., Japan). J. Phys. Soc. Jap.; 31: No. 4, 1237-9(Oct 1971).

The combination of the toroidal hf electric field and the stellarators with stellarator winding located on the major radius side is shown to be a possible stationary fusion reactor. The fusion ignition condition is attainable by the major radius compression of toroidal plasma. (auth)

58965 AVERAGED EQUATIONS OF LASER HEATING OF D–T PLASMA TAKING INTO CONSIDERATION THE HEAT OF THERMONUCLEAR FUSION. Kaliski, S. (Inst. of Fundamental Tech. Problems, Warsaw). Bull. Acad. Pol. Sci., Ser. Sci. Tech.; 19: No. 5, 397-403(1971).

Averaged equations for laser heating and expansion of D–T plasma are derived, taking into consideration the heat of thermonuclear fusion generated during this process. Despite the simplifications achieved by averaging (replacement of partial equations by ordinary ones), rejection of the propagation effects, shock waves, etc., the equation of the problem is still very complex. It is an ordinary differential equation of strong nonlinearity, with retarded argument, depending in a nonlinear manner on the solution and its derivatives. The equation of the problem can be considerably simplified, depending on the quantitative features of the problem; some particular cases are dealt with separately. (auth)

58966 HIGH-FREQUENCY HEATING IN TOKAMAKS. Klima, R. (International Centre for Theoretical Physics, Trieste, Italy). Nucl. Fusion; 11: No. 4, 357-62(Aug 1971).

The propagation of a magnetosonic wave in a tokamak device is considered, assuming plasma with two kinds of ions. The wave excited on the inner boundary of the tokamak torus penetrates into the high-density region under conditions that seem to be experimentally plausible. The energy of the wave can be absorbed in the high-density region via the Buchsbaum hybrid resonance and/or the transit time damping on electrons. (auth)

58967 PLASMA LOSSES IN HIGH-CURRENT PLASMA CONFIGURATIONS DUE TO THE INVERSE SKIN EFFECT. Kvartskhava, I. F.; Matveev, Yu. V.; Khautiev, E. Yu. (Physical-Technical Inst., Sukhumi, USSR). Nucl. Fusion; 11: No. 4, 349-55(Aug 1971).

Experiments on zeta pinches have shown that the surface layer of the plasma can be ejected towards the walls of the chamber. Phenomena of this type usually develop when the discharge current flowing through the circuit is decreasing, but they can also occur with a rising current when there is recurring discharge ignition. The application of an axial magnetic field does not prevent the surface layer of the plasma from being ejected towards the chamber walls; it merely limits the rate at which the process occurs. It is shown that the breakup of the plasma sheath is due mainly to a reverse current induced in the surface layer of the pinch. When the discharge current is decreasing, a reverse current is produced by the "inverse skin effect." It is suggested that plasma losses due to the "inverse skin effect" may also be observed for certain discharge régimes in theta-pinch, zeta, Tokamak, and other systems. (auth)

58968 STOCHASTIC MODEL OF ELECTRON-CYCLOTRON HEATING IN A MAGNETIC MIRROR. Kawamura, T.; Momota, H.; Namba, C.; Terashima, Y. (Nagoya Univ., Japan). Nucl. Fusion; 11: No. 4, 339-47(Aug 1971).

A heating mechanism of electron plasmas by high-power microwaves in a magnetic mirror is investigated theoretically, with reference to experiments in a device named TP–M. The heating is assumed to be due to a microwave mode propagating perpendicular to the magnetic field since higher harmonic resonances, the main features of the experiments, exist. The heating mechanism can be interpreted in terms of a stochastic process, a random walk in velocity space. It is confirmed numerically that localized resonance zones of finite width exist, the electrons are effectively heated only in the resonance zones, and that the presence of a randomization process of the relative phase relation between the wave and the electron gyration is essential for the heating process. On the basis of the numerical analysis, the heating process is treated analytically. The electrons are assumed to pass the resonance zones repeatedly in the course of oscillatory motions between turning points, and the relative phase relation is assumed to be random at each passage through the resonance zone. The heating rate is calculated and found to agree with the experimental value. The causes of phase randomization, the effects of the loss cone, and the observed saturation of electron temperature are also discussed. (auth)

58969 TARGET PLASMA TRAPPING. Colchin, R. J. (Oak Ridge National Lab., Tenn.). Nucl. Fusion; 11: No. 4, 329-37(Aug 1971).

The trapping of neutrals from a fast atom beam impinging on an electron–cyclotron-plasma target is studied. The electron–cyclotron plasma is assumed to be fed by an influx of molecular hydrogen. Radial attenuation of the feed gas and the H^0 formed by its dissociation is considered in detail. Both the addition of neutrals and depletion of the target by charge exchange with the beam are also taken into account, as is reflux from nearby walls. Given a sufficiently high target density ($\gtrsim 10^{13}$ protons/cm^3), a sufficiently low background density, and a 0.01 to 1.0-A neutral beam, it is calculated that 10^{11} to 10^{13} protons/cm^3 can be accumulated with a trapping efficiency of several per cent. (auth)

58970 ASPECT OF PLASMA DIFFUSION IN MULTIPOLES. Tanaka, M.; Takeda, T. (Japan Atomic Energy Research Inst., Tokai). Nucl. Fusion; 11: No. 4, 389-90(Aug 1971).

The diffusion of plasma in multipoles is considered for various directions, i.e., towards the current-carrying inner conductors and the outer wall. A brief theoretical discussion is given. (M.O.W.)

58971 PLASMA HEATING AT THE SECOND HARMONIC OF THE ELECTRON CYCLOTRON FREQUENCY. Patrushev, B. I.; Gozak, V. P.; Frank-Kamenetskii, D. A. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 542-3(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 692-3(Apr 1971).

The interaction of microwaves with plasma in a magnetic field having values close to those required for cyclotron resonance was studied experimentally in an open magnetic mirror configuration. It is found that at the second harmonic the plasma heating exhibits a resonance. Hot electrons are observed together with an instability in the form of a noise band at the third harmonic. (auth)

XU

58972 EFFECT OF MAGNETIC FIELD ON THE HEATING OF A HOT PLASMA CREATED BY AN ELECTRON BEAM. Bredikhin, M. Yu.; Maslov, A. I.; Skibenko, A. I.; Skibenko, E. I.; Yuferov, V. B. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 544-5(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 694-5(Apr 1971).

The possibility of heating a dense plasma by an electron beam injected in a magnetic mirror configuration was investigated experimentally. The heating efficiency is enhanced when the magnetic field at the center of the mirror is increased. For a constant density $N = 7 \times 10^{13}$ cm^{-3} the plasma energy density is 10^{17} eV/cm^3. (auth)

58973 COLLISIONLESS PLASMA HEATING AT THE ION CYCLOTRON RESONANCE. Cattanei, G. (Max-Planck-Institut fuer Plasmaphysik, Garching, Ger.). Phys. Rev. Lett.; 27: No. 15, 980-2(11 Oct 1971).

A variant of the method proposed by Stix for heating a plasma at the ion cyclotron resonance is presented. It is efficient for a wide range of densities and suitable for small aspect-ratio (r/R) toroidal configurations. An estimate of the resistive plasma loading is given and compared with the inductive reactance or, alternatively, with the Ohmic losses of the coil. (auth)

58974 DEPENDENCE OF THE ENERGY LOSS FROM A TOKAMAK PLASMA ON THE EFFECTIVE ELECTRON COLLISION FREQUENCY. Bobrovskii, G. A.; Razumova, K. A. JETP Lett. (USSR) (Engl. Transl.); 14: No. 3, 99-100(5 Aug 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 3, 153-4(5 Aug 1971).

In a discharge of relatively large hydrogen pressure, the electron temperature at a given current is practically independent of the density in a wide interval. Such a weak $T_e n_e$ dependence makes it possible to trace the variation of the transport coefficients with varying density or effective collision frequency ν_{eff}. Diagrams are given of plasma pressure versus ν_{eff}. (M.O.W.)

58975 INFLUENCE OF LONGITUDINAL STREAMS OF CHARGED PARTICLES ON THE DIFFUSION OF PLASMA IN A STELLARATOR. Kossyi, I. A. (Lebedev Inst. of Physics, Moscow). JETP Lett. (USSR) (Engl. Transl.); 14: No. 3, 124-7(5 Aug 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 3, 188-91(5 Aug 1971).

In order to explain the mechanism of plasma loss in closed traps, the existence of an average velocity of the ion component (u_{z_i}) along the minor axis of the toroidal chamber of the L-1 stellarator is analyzed. An earlier analysis enabled one to state that the longitudinal ion streams should of necessity arise in closed traps in the regime of weak collisional plasma with a radial electric field E_γ. Electron diffusion in the traps is described. (M.O.W.)

58976 INFLUENCE OF HIGH-FREQUENCY POTENTIAL OF A TOROIDAL ELECTRIC FIELD ON THE TRAPPING OF CHARGED PARTICLES IN A CLOSED MAGNETIC TRAP. Demirkhanov, R. A.; Stotland, M. A.; Khil, Sh. V.; Baratov, D. G. JETP Lett. (USSR) (Engl. Transl.); 14: No. 3, 122-4(5 Aug 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 3, 184-7(5 Aug 1971).

Attention is called to the fact that the toroidal inhomogeneity of the longitudinal electric field, possessed by closed traps, can lead, in the case of an hf electric field, to an increase of the degree of trapping of the particles and to a deterioration of their containment. Diagrams are given of trajectories of the particles with initial values $V_\perp/V_0 = 0.9$ on the meridional plane. The effects of hf fields are shown. (M.O.W.)

Diagnostics

58977 (AEC-tr-7271) PLASMA DENSITY MEASUREMENT BY MEANS OF AN OPEN RESONATOR. Ulshmid, I.; Bez'yazychnii, I. A. (Akademiya Nauk Ukrainskoi SSR, Kharkov. Fiziko-Tekhnicheskii Institut). Translation of report KHFTI-69-51. 19p. Dep. NTIS.

A survey is given of plasma density measurements in a metal chamber using an open-resonator method. The performance of the open-resonator method is discussed. (M.O.W.)

58978 (CEA-CONF-1829) OPTICAL METHOD FOR STUDYING THE ION VELOCITY IN AN ACCELERATED PLASMA BEAM. Hess, W. R. (Commissariat a l'Energie Atomique, Grenoble (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-7). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

Charge exchange with excitation from energetic ions in a residual neutral gas in plasma experimental devices can be used for plasma diagnostics. An optical method for measuring the proton velocity distribution in a hot plasma source is described. (France)

58979 (JAERI-Memo-4530) MICROWAVE INTERFEROMETRIC MEASUREMENTS IN THE MEDIUM-BETA TORUS (JFT-2). Funahashi, Akimasa; Itoh, Satoshi (Japan Atomic Energy Research Inst., Tokyo). Jul 1971. 24p. (In Japanese). Dep. NTIS (U. S. Sales Only).

Eight-channel, 2-mm microwave interferometric measurements were made in order to determine the distribution of plasma density in the Tokamak-type apparatus, JFT-2. The plasma density measurements performed in Tokamak apparatus are first reviewed. Then, the 2-mm wave measurements in the JFT-2 apparatus are explained in detail, including the multichannel interferometric circuits and the numerical method of determining the density distributions without axial symmetry from the measured phase shifts. In addition, the refractive shift of the 2-mm wave path due to the radial distribution of plasma density is also discussed. The report is expected to be a manual for obtaining the density distributions from the observed interferometric traces. (auth) (Japan)

58980 (JAERI-Memo-4531) MEASUREMENT OF THE PLASMA CURRENT DISTRIBUTION IN A TOKAMAK DEVICE WITH ALPHA-PARTICLES INJECTED TRANSVERSE OR PARALLEL TO THE TOROIDAL AXIS. Kawasaki, S.; Inoue, K.; Takeda, T.; Yoshikawa, M. (Japan Atomic Energy Research Inst., Tokai. Tokai Research Establishment). Jul 1971. 31p. Dep. NTIS (U. S. Sales Only).

A method is proposed for measuring the current distribution in a tokamak plasma column by injecting α particles from a radioisotope. In this method, the plasma current distribution is determined by injecting the α particles into a plasma column and analyzing their orbits with and without the plasma current. The orbit analysis is presented for the axisymmetric linear geometry. The deviation calculated for the JFT-2 tokamak parameters indicates that the present method is feasible. The problems of measurement resolution, toroidal effect, α source, and detector are also described. (auth) (Japan)

58981 EFFECT OF ELECTRON AND ION DRIFTS ON DOUBLE PROBES. Ariga, Seiichi (Kyoto Univ.). J. Phys. Soc. Jap.; 31: No. 4, 1221-31(Oct 1971).

The characteristics of double probes immersed in plasmas in which electrons and ions have drifted Maxwellian distributions are theoretically investigated by computer. The results about a double probe with "two frontal electrodes" show that the electron drift changes the inclination of the characteristic curve; therefore, the electron temperature estimated from the curve contains an appreciable error. On the contrary, the results about a probe with "back-to-back electrodes" show that the electron drift shifts the idealized characteristic curve parallel to the potential axis of the figure and the ion drift parallel to the current axis, but the original pattern is still conserved; therefore, the estimated temperature is valid in this case when the drift velocity of electrons or ions is far lower than their thermal velocity. (auth)

58982 THEORY OF A COOLED SPHERICAL ELECTROSTATIC PROBE IN A CONTINUUM GAS. Chapkis, Robert L.; Baum, Eric (TRW Systems Group, Redondo Beach, Calif.). AIAA (Amer. Inst. Aeronaut. Astronaut.) J.; 9: No. 10, 1963-8 (Oct 1971).

The idealized problem of a cooled spherical electrostatic probe in a quiescent continuum slightly ionized chemically frozen gas was investigated. The electron temperature is described by two limiting models; either the electrons are assumed to be at local thermal equilibrium, or they are assumed frozen at the ambient temperature far from the probe. From numerical solutions of the governing equations, it was found that with the frozen electron temperature assumption, the probe characteristics for a cold probe are only slightly altered from those of an adiabatic probe. With the electrons at thermal equilibrium, the probe characteristic is only slightly altered when the bias potential is large, but significant changes in the probe characteristics do occur when the bias potential is small, including a significant shift in the floating potential. (auth)

58983 PROBE GEOMETRY EFFECTS ON TURBULENT PLASMA DIAGNOSTICS. Ghosh, A. K.; Richard, C. (RCA Victor Co., Ltd., Montreal). AIAA (Amer. Inst. Aeronaut. Astronaut.) J.; 9: No. 10, 2104-6(Oct 1971).

XUM

Studies were made on the perturbing effects of probe geometry on the turbulent plasma parameters when they are used to measure the local statistical properties of turbulent plasma flows. The effects studied are: 1) frequency filtering effects of the cylindrical electrostatic probes on the power-frequency spectrum when placed axially along the turbulent plasma flow. 2) The "wake" effect of an upstream probe on a downstream probe when the pair is used to measure various statistical moments of the turbulent plasma flow. (M.O.W.)

58984 INTERFEROMETRIC DETERMINATION OF TEMPERATURE IN A LAMINAR JET OF ARGON OR NEON PLASMA. Czernichowski, A. (Wroclaw Technical Univ.). Acta Phys. Pol.; A40: No. 3, 283-94(Sep 1971).

A Mach–Zehnder interferometer and an He–Ne laser were used in determinations of the temperature in a laminar jet of argon or neon plasma achieved in a plasmatron. Presented here are the measuring technique, the equipment used, and the numerical method of analyzing the interferograms of the jets of axial symmetry. (auth)

58985 PLASMA TEMPERATURE DETERMINATIONS NEAR A DIELECTRIC SURFACE. Andreev, S. I.; Gavrilov, V. E. Zh. Prikl. Spektrosk.; 14: No. 3, 524-7(Mar 1971). (In Russian).

Plasma temperature was determined at a quartz wall boundary. In the case when a radiative energy stream predominates, the temperature of the plasma remains high in the boundary layer 10^{-2} cm thick and comprises approximately 80% of the temperature of the plasma measured 1 to 2 mm distant from the wall. (tr-auth)

58986 MEASUREMENT OF THE PARAMETERS OF A CESIUM PLASMA. COMPARISON OF THE RESULTS OBTAINED USING A HOT LANGMUIR PROBE WITH THOSE OBTAINED USING A COOLED PROBE. Michel, Claude; Kornmann, Michel; Cussenot, J. R. (Nancy Univ.). Compt. Rend., Ser. B; 272: No. 24, 1350-3(14 Jun 1971). (In French).

When the parameters of a hot-cathode cesium plasma are determined with a Langmuir probe, secondary emission currents from the collector surface and a poorly defined work function can introduce considerable error. These inconveniences can be suppressed by cooling the collector surface. (France)

58987 EXPERIMENTAL DETERMINATION OF THE ELECTRON CONCENTRATION AND TEMPERATURE OF AN ARGON PLASMA JET BY MEANS OF LASERS. Aksenov, V. V.; Bespalov, M. S.; Eroshenko, V. M.; Mushinskii, A. A. Zh. Prikl. Spektrosk.; 14: No. 3, 393-6(Mar 1971). (In Russian).

The electron temperature and density were experimentally determined by means of a laser of modulated figure of merit. An argon plasma jet was obtained at atmospheric pressure in a water-cooled 3.5 KV plasmatron. The electron temperature and concentration were derived from the spectrum of scattered radiation, and are equivalent to the corresponding values obtained from the spectroscopic method. (tr-auth)

58988 TEMPERATURE MEASUREMENT OF HEAVY PARTICLES IN A PLASMA IN A MAGNETIC FIELD. Khmelinin, B. A. Zh. Prikl. Spektrosk.; 14: No. 1, 37-40(Jan 1971). (In Russian).

The method of measuring the temperature of atoms and ions according to the Doppler broadening of lines during the combined effects of Doppler and Zeeman was investigated for the case when it is possible to neglect relatively small concentrations of electrons by the Stark effect. The dependence of the Doppler line broadening on the experimental half-width was calculated for a series of lines of neutral and ionized argon. The limiting concentration of electrons was calculated as a function of the measured temperatures for a series of argon lines. (tr-auth)

58989 DEVICE FOR MEASUREMENT OF TIME-RESOLVED PROFILES OF A LINE SPECTRUM EMITTED FROM A PLASMA. Goto, Seiichi; Ishimura, Tsutomu (Osaka Univ.). Jap. J. Appl. Phys.; 10: No. 10, 1450-8(Oct 1971).

A device is constructed to display eight successive time-resolved profiles of a spectral line from a pulsed plasma on the screen of a usual oscilloscope. It takes 2 μs to display one profile and the time interval between two successive profiles is chosen to be 10, 15, 20, or 30 μs. The wavelength band width of each picture on the screen is chosen to be 15, 10, or 6.3 Å. The device is composed of a grating monochromator, a set of 3 light guides of 16 channels, and an electronic signal processor. The signals corresponding to the 16 wavelength components are sampled and mixed in the processor so that the resultant signal is fed to the vertical input terminal of the oscilloscope. Simultaneously, the horizontal sweep and the brightness modulation waveforms are produced by the processor and applied to the corresponding terminals. (auth)

58990 DOUBLE MICROFIELD PROBE. Storey, Owen; Chauliaguet, Charles (Centre National de la Recherche Scientifique, Saint-Maur-des-Fosses, France). Compt. Rend., Ser. B; 272: No. 26, 1496-9(28 Jun 1971). (In French).

It is suggested that the electron density and electron temperature of a plasma may be determined from measurements made as a function of frequency of the crossed spectra of two random signals received by two small dipole antennas in the medium. These spectra were studied for a plasma in thermal equilibrium, without a magnetic field, and free from collisions. It presents a maximum just above the plasma frequency; this maximum becomes sharper on increasing the separation of the antennas in relation to the Debye length. (France)

58991 SPECTRAL DIAGNOSTICS OF ARGON AND NEON PLASMAS IN PSEUDO EQUILIBRIUM. Czernichowski, A. (Ecole Polytechnique, Wroclaw). Acta Phys. Pol.; A40: No. 3, 295-308(Sep 1971). (In French).

Using spectral methods, electron density distributions and the excited-state density of Ar I and Ne I in a laminar jet of argon and neon plasma produced in a plasmatron were studied. The parameters for the temperature distribution of neutrals were compared. This distribution was determined with the help of a Pitot tube and the Mach–Zehnder interferometer. It was found that the populations relative to all the excited levels as well as the electron density correspond to equilibrium for the temperature of the neutrals (about 4000°K), but that the absolute values of the populations are very high and correspond to a temperature of 10,000°K. (tr-auth)

58992 PLASMA POTENTIAL MEASUREMENT. Makov, B. N. Dokl. Akad. Nauk SSSR; 198: No. 2, 327-9(11 May 1971). (In Russian).

An electrode immersed in a plasma, and with a different potential, is surrounded by a narrow region of space charge, the thickness of which is determined by the Child–Langmuir law. A novel method of determining the plasma potential is offered if the space charge is absent on the surface of the probe, a condition which evidences a disappearance of electrical field between the probe and the plasma. A schematic diagram of the probe circuitry is provided, and its mode of operation is outlined. (K.S.W.)

58993 DETERMINATION OF PLASMA PARAMETERS ACCORDING TO INTENSITY OF CONTINUOUS SPECTRA. Chelnokov, M. B. (Moscow Aviation Inst.). Izv. Vyssh. Ucheb. Zaved., Fiz.; No. 1, 12-17(1969). (In Russian).

The relation between the spectral intensity of recombination radiation and the recombination coefficient is obtained. It is shown that determination of electron temperature according to the intensity of the continuous spectra is possible even in the unknown relation of intensities of recombination and bremsstrahlung. Methods are developed for determination of recombination coefficients and electron velocity distribution functions according to the intensity of the continuous spectra. (tr-auth)

58994 CORPUSCULAR PLASMA DIAGNOSTICS. Afrosimov, V. V. (Ioffe Inst. of Physics and Tech., Leningrad). pp 535-62 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Plasma energy loss determination by measurement of associated particle fluxes is described. Plasma diagnostics using interacting charged-particle beams are then discussed. 26 references. (M.O.W.)

58995 METHODS OF PLASMA INVESTIGATION BY MICROWAVE REFLECTION. Ipatov, V. A. (Ioffe Inst. of Physics and Tech., Leningrad). pp 614-33 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

The application of the reflected-wave method in plasma diagnostics is discussed and it is shown that the region of applicability can be extended to the range of density from n = 0 to n = $10^4 n_{cr}$. (M.O.W.)

58996 METHODS OF INVESTIGATION OF TURBULENT PHENOMENA IN PLASMA BY SCATTERING OF SHF WAVES. Larionov, M. M. (Ioffe Inst. of Physics and Tech., Leningrad). pp 634-52 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Theoretical analyses are presented for different cases of super-high-frequency wave scattering on various fluctuations in turbulent plasmas. Various incident angles for the shf waves are considered in particular. (M.O.W.)

58997 EXPERIMENTAL INVESTIGATION AND APPLICATION TO PLASMA DIAGNOSTICS OF THE DOPPLER EFFECT AT THE CYCLOTRON FREQUENCY. Ivanov, B. I. (Physical-Technical Inst., Kharkov). pp 653-77 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

The possibility of application of the Doppler effect at the electron cyclotron frequency for the investigation of electron longitudinal velocity distributions in plasmas and beams is considered. Relations establishing the correspondence between the line profile of cyclotron damping and the electron distribution function are given. The Doppler effect at the electron cyclotron frequency is studied experimentally. The measurements are carried out on an electron beam passing along the axis of an overmoded cavity in the 10-cm band. Both nonrelativistic and relativistic Doppler shifts of the electron cyclotron frequency were observed. On the basis of these investigations, a new shf method for the electron distribution functions is proposed. The method is used to determine the electron velocity distribution in a beam–plasma discharge. A comparison of the new method with the retarding-potential method was made and satisfactory results were obtained. An advantage of the newly developed method is the possiblity to measure the absolute (not relative) values of the velocity distribution function without introducing perturbing bodies in contact with the plasma. (auth)

58998 INVESTIGATIONS IN PHYSICAL CHEMISTRY OF THE ARC PLASMA. Vukanovic, V. (Univ., Belgrade). pp 706-28 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Spectral analysis of a gaseous plasma in free-burning arcs is discussed from the physical chemistry standpoint. A brief theoretical analysis of the problem is presented. (M.O.W.)

58999 BEHAVIOUR OF LOW-DENSITY PLASMA IN THE PRESENCE OF CYLINDRICAL LANGMUIR PROBES. Szuszczewicz, E. P.; Weber, A. H. (St. Louis Univ.). pp 147-51 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

It is stated that although the use of electrostatic probes in plasma diagnostics has had a relatively long history, the problem of interpreting Langmuir probe current–voltage characteristics is not completely solved for the entire range of probe–plasma parameters. The theoretical and experimental work done in this field is reviewed, and in particular that of Laframboise (UTIAS Report No. 100(1966)). Both collisionless plasmas and collision effects are discussed, and particular reference is made to OML (orbital motion limited) current behavior. (UK)

59000 PLASMA DIAGNOSTICS OF A URANIUM PLASMA. Schneider, R. T.; Kylstra, C. D.; Campbell, H. D. (Univ. of Florida, Gainesville). pp 157-61 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

The development of plasma core nuclear reactors for propulsion or other applications such as nuclear pumped lasers will require a knowledge of the radiation emitted by uranium plasmas as a function of operating pressures, temperatures, wavelengths, and geometry. A knowledge is also needed of plasma composition (partial pressure distribution of the various U ionic species and the electrons). Calculations concerning criticality, radiative heat transfer to the working fluid, and system startup and control all require this information. These calculations must at present rest on theoretical predictions of radiation emission and plasma composition, but little is known concerning U plasma physical constants, particularly at the temperatures and pressures usually quoted for propulsion plasma core reactors. Some initial measurements on a U plasma are described, together with the diagnostic methods developed to analyze the data. The measurements included emission and absorption coefficients as a function of pressure and temperature, and results are reported for a plasma of pressure 0.1 to 0.5 atm. at 7,500 to 10,000K. Novel methods for diagnosing U plasmas were developed. (UK)

59001 PLASMA DIAGNOSTICS UTILISING OPTICAL INTERFEROMETRY AND HOLOGRAPHIC TECHNIQUES. Friedrich, O. M. (Univ. of Texas, Austin); Weigl, F.; Dougal, A. A. pp 557-61 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

It is stated that two-beam optical interferometry and holographic techniques are very valuable for space- and time-resolved quantitative measurements of the refractive index of transparent media, and the possibility of using optical holography for plasma diagnostics was demonstrated by Ostrovskaya and Ostrovskii in 1966; employing holographic techniques they determined the refractive index of the plasma produced by a laser-induced spark. The principles of holography are outlined and it is stated that a hologram permits storing light waves that have passed through a plasma and later studying changes introduced in the light waves by the plasma. Advantages of optical holographic techniques for plasma diagnostics include the possibility of determining the spatial distribution of plasma parameters, optical recording which can be made insensitive to the self-radiation of the plasma, optical interferometry without high-quality optical windows on the plasma vessel by employing double-pulse differential holographic interferometry, and variable-sensitivitv interferometry. These aspects are discussed in detail. (UK)

59002 LOW-PRESSURE TOROIDAL GLOW DISCHARGE IN THE RADIAL MAGNETIC FIELD. Pekarek, S. (Czech Technical Univ., Prague). Czech. J. Phys.; 21: No. 9, 930-5 (1971).

The behavior of the plasma of a low-pressure toroidal glow discharge in a radial magnetic field is studied experimentally. Results concerning the plasma velocity as a function of the magnetic field for different pressures are given. (auth)

59003 MEASUREMENT OF ATOMIC METASTABLE DENSITIES IN NOBLE-GAS PLASMAS CREATED BY NUCLEAR RADIATIONS. Guyot, Jean Charles. Urbana, Ill.; Univ. of Illinois (1971). 243p. University Microfilms Order No. 71-21,132. Thesis.

Measurement of metastable densities in He, Ne, and He–Ne plasmas is reported. The University of Illinois TRIGA Nuclear Reactor was operated in the pulse mode to provide a source of neutrons to induce ionization and excitation in these gases, via the nuclear reaction $^{10}B(n,\alpha)^{7}Li$ in a boron coating on the walls of the gas container. An optical absorption technique was used wherein a light source illuminated the gas under investigation, which was in a cell placed near the core of the reactor. This cell contained boron-coated aluminum tubes providing the source of heavy charged particles. The amount of the light at a given wavelength traversing the cell was measured during a reactor pulse. These absorption data were interpreted in terms of metastable densities, including a correction due to pressure broadening. The experiments covered a gas pressure range from ~0 to 1000 torr, with neutron fluxes from 10^{12} to 10^{16} n/cm^{-2}-sec. The He(2^1S)- and He(2^3S)-metastable densities in pure helium were studied, as well as the Ne($1s_5$)- and Ne($1s_3$)-metastable densities in pure neon and (9/1) helium–neon mixtures. These results are presented graphically versus gas pressure and neutron flux. Also, a value of the He(2^3S) density equal to 1.5×10^{10} atoms/cm^3 was measured in a (9/1) He–Ne mixture, at a total pressure of 163 torr, for a flux of 4.3×10^{15} n/cm^2-sec. Gain-measurement experiments were conducted at 3.39 and 1.15μ in He–Ne to investigate the possibility of an inversion of population between known laser levels. There appears to be a small gain at both wavelengths (less than 4% per meter), but the present detection technique was not sensitive enough to unambiguously prove its existence. A theoretical model developed describes the transport of heavy-charged particles and the plasma kinetics. In general, this model predicted the behavior of the metastable densities quite well, the largest discrepancy being for the case of the He(2^3S) density in pure He. It would, however, predict a gain at 3.39μ larger than observed experimentally. Gain and absorption experiments in He–Ne at higher pressures (700 to 1000 torr) were hampered by the appearance of an anomalous effect tentatively attributed to the formation of a gas lens due to uneven heating of the high-pressure gas. (Diss. Abstr. Int., B)

59004 COMPUTER SIMULATION OF ELECTRICAL BREAKDOWN IN GASES. Kline, Laurence Earl. Pittsburgh; Carnegie-

Mellon Univ. (1971). 174p. University Microfilms Order No. 71-20,637.

Thesis.

A new method is presented for the simulation of electrical breakdown phenomena, and plasma phenomena where both binary electron–neutral gas molecule collisions and collective interactions among charged particles are important. Elastic, exciting, and ionizing electron–neutral gas molecule collisions are included using a Monte Carlo technique. Electron–ion pairs are released in ionizing collisions. Collective interaction is included using a one-dimensional plasma model that regards the charged particles as charge sheets. Poisson's equation is solved in one dimension based on the positions of the charge sheets to find the accelerating forces on the sheets. The simulation also includes the release of electron–ion pairs by photoionization. The method is used to simulate the growth of electron avalanches and electron streamers in nitrogen-filled parallel plane gaps. Avalanche simulation results are used to calculate values for three transport coefficients: the drift velocity, ionization coefficient, and characteristic energy in nitrogen. The calculated values of the transport coefficients agree with experimental values over a wide range of E/p, the applied electric field divided by the pressure. Velocities for anode- and cathode-directed streamers are calculated based on the streamer simulation results. The calculated streamer velocities agree with available experimentally measured streamer velocities. The streamer simulation results also show that photoionization is an important mechanism in streamer growth. (Diss. Abstr. Int., B)

59005 ARC DISCHARGES IN STRONG MAGNETIC FIELDS. Wienecke, R. (Univ., Stuttgart). pp 687-93 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Thermodynamic properties of an electric arc are discussed. The effects of an external magnetic field on the energy balance in an arc are described. Some experimental results are shown. (M.O.W.)

59006 VACUUM-UV EMISSION OF HIGH-DENSITY PLASMA GENERATED IN WALL-STABILIZED ARC. Mueller, D. (Max-Planck Inst., Munich). pp 694-705 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

A wall-stabilized argon arc for spectroscopic measurements in the vacuum-uv range is described. Temperature measurements and atomic-parameter measurements in the arc are discussed. (M.O.W.)

59007 RELAXATION AND TEMPERATURE DIFFERENCE IN QUASI-LINEAR APPROXIMATION FROM CALCULATIONS OF COLLISIONS FOR MAGNETOACTIVE PLASMA. Machabeli, G. Z. Zh. Prikl. Mekh. Tekh. Fiz.; No. 2, 47-51(Mar-Apr 1969). (In Russian).

Equations for longitudinal waves were obtained in the quasilinear approximation from calculations of collisions for plasma placed in a constant magnetic field. The contribution to the relaxation of temperatures of a two-component plasma as a result of the interaction of waves with resonance particles is obtained. The difference of temperatures of electrons and ions in the steady-state case and also the perpendicular and parallel difference in relation to magnetic field of constituent temperatures for each type of particle in the electric field of the wave are found. (tr-auth)

59008 POPULATION OF EXCITED ATOMIC STATES AND IONIZATION IN A NONEQUILIBRIUM CESIUM PLASMA AT LOW PRESSURE. Chelnokov, M. B. (Moscow Aviation Inst.). Izv. Vyssh. Ucheb. Zaved., Fiz.; No. 1, 52-6(1969). (In Russian).

The system of nonlinear algebraic equations was obtained for determination of the population of 20 lower levels of cesium in nonequilibrium low-pressure plasma, with consideration of high output from the elementary processes. Solutions for this system were accomplished by computer. Results were compared with experimental results of the literature, and agreement was satisfactory. Results of the solution obtained, besides level populations, were ionization coefficients and concentrations of molecular ions of cesium. It was found that the ionization yield is maximum at the $6P_{1/2}$ level, after which it falls rapidly so that the lower 20 levels give practically all of the ionization yield. Therefore, disregard of the other levels does not introduce errors in calculation of the ionization coefficient. (tr-auth)

59009 GAS DISCHARGES. International Conference Held in London, 15–18 September 1970. Conference Publication No. 70. London; Institution of Electrical Engineers (1970). 599p. (CONF-700969).

122 papers were presented at this conference. Separate abstracts were prepared for eleven of these. (UK)

For abstracts of individual papers see: 57902, 58950, 58999–59001, 59010, 59011, 59022, 59023, 59072, and 59080.

59010 ESTIMATION AND MEASUREMENT OF ELECTRON LOSSES FROM AVALANCHES IN HYDROGEN. Allen, N. L.; Mitchell, P. (Univ. of Leeds, Eng.). pp 53-7 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

The situation is discussed in which the breakdown of a plane-paralled gap, in the region of the Paschen minimum, is influenced by the proximity of walls or other surfaces. In particular, electron diffusion loss from an avalanche is considered. An electron avalanche expands by diffusion, and preliminary experiments showed that the resulting absorption of particles by the containing walls leads to an increase in breakdown potential. A model is adopted to calculate particle losses from avalanches, and the results are compared with experimental data obtained by measurement of pre-breakdown currents in a cylindrical tube. This model offers an alternative to the rigorous analytical approach of Lucas (Proc. IEE, 2: 867(1969)). In the experimental work, extensive sets of wall and anode current measurements were made in H_2. (UK)

59011 MERCURY ELECTRON-BOMBARDMENT ION THRUSTERS. King, H. J. (Hughes Aircraft Co., Malibu, Calif.). pp 262-5 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

It is stated that ion propulsion has two immediate applications: primary propulsion for unmanned space probes or raising of communication satellites to synchronous orbit; and control propulsion to position or reorientate a satellite with respect to some fixed reference. Details are given of prime propulsion systems and their applications and satellite attitude control and station keeping systems. Two designs of mercury electron-bombardment ion thrusters are described, each having a sufficiently high performance to fulfill requirements for current space missions, and in which the hollow cathode was improved so as to provide electron currents of 10 A or more without showing any visible erosion after 500 hours, and the useful life of which is at least ten times this period. An electrical isolator system was developed to permit all thrusters in an array to be operated simultaneously from a single grounded mercury reservoir without electrical interaction between the thrusters; this is essential to make best use of the mercury propellant whilst still permitting one thruster to sustain an electrical short to ground without making all thrusters inoperative. (UK)

59012 (CEA-CONF-1833) DEFORMATION OF THE ELECTRON DISTRIBUTION FUNCTION UNDER THE INFLUENCE OF A LARGE AMPLITUDE WAVE. Guillemot, M.; Olivain, J.; Perceval, F.; Quemeneur, A. (Commissariat a l'Energie Atomique, Fontenay-aux-Roses (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920–6). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

The deformation of the electron distribution due to its interaction with a large-amplitude plasma wave is measured and shows good agreement with theoretical predictions. (France)

59013 (CEA-CONF-1835) NONLINEAR HARMONIC GENERATION IN A THERMAL MAGNETIZED PLASMA. Cano, R.; Fidone, I.; Schwartz, M. J.; Zanfagna, B. (Commissariat a l'Energie Atomique, Fontenay-aux-Roses (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920–2). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

An experiment is discussed in which a radiation was observed at the second harmonic of an incident microwave beam. The experimental results are in good agreement with the theory of nonlinear harmonic generation in inhomogeneous plasmas. (France)

59014 ION PRODUCTION AND LOSS PROCESSES IN HELIUM-NITROGEN MIXTURES. Maerk, Tilmann D.; Oskam, H. J.

(Univ. of Minnesota, Minneapolis). Phys. Rev., A: 4: No. 4, 1445-52(Oct 1971).

Detailed studies of the time dependence of the number density of ions were made during the decay period of plasmas produced in He containing various concentrations of nitrogen molecules. Various reaction-rate constants were obtained: He $(2\ ^3S) + N_2 \rightarrow N_2^+ + He + e$ $[(6.3 \pm 1.0) \times 10^{-11}$ cm^3 sec$^{-1}]$; $N_2^+ + N_2 + He \rightarrow N_4^+ + He$ $[(5.3 \pm 0.3) \times 10^{-30}$ cm^6 sec$^{-1}]$ and $N^+ + N_2 + He \rightarrow N_3^+ + He$ $[(4.6 \pm 0.4) \times 10^{-29}$ cm^6 sec$^{-1}]$. Evidence for the charge-transfer process $N_2^+ + N \rightarrow N^+ + N_2$ was obtained. The values of the ambipolar-diffusion coefficients of nitrogen ions in He were found to be $D_ap_0(N^+) = 970 \pm 50$; $D_ap_0(N_2^+) = 920 \pm 40$, and $D_ap_0(N_3^+) = 840 \pm 70$ cm^2 sec^{-1} torr, while the diffusion coefficient of He $(2\ ^3S)$ was $D_mp_0 = 480 \pm 30$ cm^2 sec^{-1} torr. (auth)

59015 ROLE OF RECURRING DISCHARGE IGNITION IN A DYNAMIC Z PINCH. Kvartskhava, I. F.; Matveev, Yu. V. (Physical-Technical Inst., Sukhumi, USSR). Nucl. Fusion; 11: No. 4, 385-7(Aug 1971).

Several of the unexplained properties of a dynamic z pinch are considered. The singularities observed when there are distinct breaks in the voltage and discharge current oscillograms are analyzed. The m = 0 instability and the processes occurring at the electrodes of the pinch are then discussed. (M.O.W.)

59016 PROPERTIES OF DENSE HELIUM PLASMA IN RECOMBINATION STAGES. Razmadze, N. A.; Chkuaseli, Z. D.; Sholin, G. V. Zh. Prikl. Spektrosk.; 14: No. 1, 30-3(Jan 1971). (In Russian).

The contours and intensity of the spectral lines of He II 4686 Å and He I 4471 Å were measured in a collapsing helium arc formed by means of an electrodeless pulse discharge of average power. The electron concentration was accordingly calculated to be between 10^{17} and 10^{16} cm^{-3}, the temperature 6 to 1 eV. The estimate of the recombination coefficient (10^{-12} to 10^{-11} cm^3/sec) supports the impact-radiative mechanism of plasma decay. (tr-auth)

59017 PLASMA PARAMETERS AND THE POPULATION OF EXCITED ATOMIC STATES IN A LOW-CURRENT HELIUM ARC. Gol'dfarb, V. M.; Il'ina, E. V.; Kasakov, A. I. Zh. Prikl. Spektrosk.; 14: No. 1, 34-6(Jan 1971). (In Russian).

A plasma column of a helium arc (10 A) was used at atmospheric pressure. The temperature of the atoms and electrons on the discharge axis was about 7,000 and 15,000°K. The concentration of the electrons, determined by the broadening of the H_β line of He, was 8×10^{14} cm^{-3}. The population of the upper levels of He was noticeably smaller than equilibrium. The distribution temperature, determined by the relative population levels ($n_1/n_2 = 3/4$; $3/5$), was close to gas temperature. Possible causes of a significant non-equilibrium of the plasma are discussed. (tr-auth)

59018 INTERACTION OF ARGON AND NEON PLASMAS IN PSEUDO EQUILIBRIUM WITH ADDITIONS. Czernichowski, A. (Ecole Polytechnique, Wroclaw). Acta Phys. Pol.; A40: No. 3, 309-13(Sep 1971). (In French).

Experiments were carried out on the interaction of plasmas of argon or neon in pseudo equilibrium with nitrogen, oxygen, hydrogen, helium, neon, carbonic gas, and pentane. Spectroscopic observations show the role of the metastable states as well as the role of the resonance radiation in the establishment of equilibria in argon or very pure neon plasma. The reduction of the argon or neon plasma in pseudoequilibrium with a local thermodynamic equilibrium state can be made with the help of additions having quantum or continuous internal energy states situated near resonance levels or near metastable levels of the principal components of the plasma. (tr-auth)

59019 PRODUCTION AND LOSS OF N_2^+, Ne^+ AND Ne_2^+ DURING THE DECAY PERIOD OF PLASMAS PRODUCED IN NEON–NITROGEN MIXTURES. Maerk, Tilmann D. (Univ., Innsbruck); Oskam, H. J. Z. Phys.; 247: No. 1, 84-94(1971).

Studies of the time dependencies of the number density of N_2^+, Ne^+, and Ne_2^+ ions were made during the decay period of plasmas produced in neon containing various concentrations of nitrogen molecules. Reaction rate constants were obtained for $N_2^+ + N_2 + Ne \rightarrow N_4^+ + Ne$ $((1.2 \pm 0.2) \times 10^{-29}$ cm^6 sec$^{-1})$ and $Ne^+ + N_2 \rightarrow N_2^+ + Ne$ $((2.9 \pm 0.3) \times 10^{-12}$ cm^3 sec$^{-1})$. The ambipolar diffusion coefficient of N_2^+ in neon was found to be $D_ap_0 = 350 \pm 20$ cm^2 sec^{-1} torr. (auth)

59020 EVOLUTION OF TURBULENT ELECTROSTATIC SHOCKS. Wong, A. Y.; Means, R. W. (Univ. of California, Los Angeles). Contract AT(11-1)-34. Phys. Rev. Lett.; 27: No. 15, 973-6(11 Oct 1971).

Turbulent low-Mach-number electrostatic ion shocks are observed when ion reflections ahead of shocks are controlled by new methods. The spatial growth of the turbulence is mapped by a test-wave method and correlated with the distribution of reflected ions. Disagreements with computer experiments are explained. (auth)

59021 HIGH-TEMPERATURE ELECTRON PLASMA BY SLOW MIRROR THETA PINCH. Shiina, Syoiti; Ohnishi, Haruyuki; Murata, Hideo; Sato, Kazuo; Mashiba, Tadashi (Tokyo Coll. of Science and Engineering). Kakuyugo Kenkyu; 26: No. 2, 93-111(Mar 1971). (In Japanese).

The hot electron plasma of 50- to 80-keV average energy is produced by the slow theta-pinch helium discharge and confined in the magnetic mirror field (mirror ratio 1:1.48). The density of the confined plasma ($\gtrsim 10^{13}$/cm^3) is higher than that of the plasmas produced by other methods of the hot electron plasma production. The confinement time is about 200 μsec; this value can be explained by the multiple scatterings of the hot electrons with neutral atoms. The plasma column is a little deformed, but the deformation does not grow during 200 μsec. During the low-density phase in the discharge, a burst of hot electrons is observed across the magnetic lines of force. The radial burst occurs at the midplane of the mirror field, and is not observed at the mirror plane. The time of the occurrence of the burst depends sensitively on the initial gas pressure or cold electron density. The radial burst arises from the flute-type instability, which is conditioned by the cold-to-hot density ratio. The axial loss of hot electrons along the magnetic lines of force is also observed independently of the radial burst and independently of the initial gas pressure. The axial burst is composed of hot electrons with energies below 90 keV. The energy distribution of escaping hot electron flux shows a non-Maxwellian distribution, which does not significantly change before and after the burst. The burst is observed in the plasma condition $\omega_{pe}/\omega_{ce} \lesssim 1$. The buildup time of the burst is a few microseconds, much greater than that of the radial burst. The mechanisms of axial burst are discussed. (auth) (Japan)

59022 INITIATING AN INTENSE DISCHARGE PLASMA AT VERY LOW GAS PRESSURES WITH THE HELP OF AN AUXILIARY DISCHARGE. Chandraker, K. (Univ. of Salford, Eng.). pp 58-62 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

An experimental investigation is described with a view to producing a plasma of high degree of ionization at gas pressures of 10^{-6} to 10^{-3} torr. Difficulties arise in starting an electrical discharge under vacuum conditions, and various methods were devised with a view to overcoming this. In the experiment described an auxiliary discharge was first started between one of the main electrodes and an auxiliary electrode located in the vicinity of the former and a voltage then applied between the main electrodes to initiate an intense electrical discharge. Most of the preliminary observations were made with H_2, but He and Ne were subsequently used to ascertain whether the nature of the gas had any effect on development of the discharge. Details are given of the development of the auxiliary and main discharges. (UK)

59023 PROPERTIES OF A HIGH-CURRENT DISCHARGE IN ALKALI-METAL-SEEDED RARE GASES. Ellington, H. I. (Robert Gordon Inst. of Tech., Aberdeen, Scotland); Dunn, P. D. pp 313-17 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

The discharge described is stated to have potential applications in the field of closed-cycle magnetohydrodynamic power generation, and shows some unusual features that make it of considerable scientific interest. It carries a current of the order of amps between plane-metal electrodes immersed in atmospheric-pressure He, Ne, or Ar at 800 to 1250°K to which a small quantity of Cs, K, or Na vapor is added as an easily ionized seed, and operates at an applied voltage of a few volts or tens of volts when the electrode spacing is a few mm or cm, respectively. It appears to consist of two distinct regions—a thin highly luminous sheath covering the entire cathode surface and a brightly glowing cylindrical positive column extending from the anode surface to within a mm or so of the cathode surface, diverging and becoming fainter as it nears the latter. The two luminous regions are separated by a narrow but clearly visible dark space. The interelectrode potential drop also consists of two distinct parts— a sharp voltage drop immediately in front of the cathode surface, and a uniform drop along the positive column. The process by which the discharge is initiated is first examined, followed by an examination of the discharge itself, dealing in turn with the cathode regions and positive column. (UK)

XUM

59024 FINE STRUCTURE OF THE DISTRIBUTION FUNCTION OF IONS IN THE PLASMA OF A STRONG-CURRENT z DISCHARGE. Gosteva, T. S.; Fedyakov, V. P. JETP Lett. (USSR) (Engl. Transl.); 14: No. 3, 103-5(5 Aug 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 3, 158-60(5 Aug 1971).

The spectra of ions leaving the plasma of a strong-current z discharge along the field through the mirrors, and also of the neutrals leaving in a direction transverse to the field were studied. The experimental conditions were: discharge current 20 to 40 kA, plasma diameter ~7 cm, longitudinal field $H_0 \sim 2kOe$, initial hydrogen pressure in the chamber $p \sim 10^{-4}$ to 6×10^{-3} mm Hg. (M.O.W.)

59025 (CEA-CONF-1832) ACCESSIBILITY OF EXACT NONLINEAR STATIONARY STATES IN WATER-BAG MODEL COMPUTER EXPERIMENTS. Finzi, U. (Commissariat a l'Energie Atomique, Grenoble (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-5). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

The initial configuration was assumed to be a uniform state which has the same constants of motion as a Bernstein–Greene–Krushal (BGK) periodic stationary state, and an initial perturbation of finite amplitude and whose wavelength is equal to the periodicity length of this stationary state was applied to it. Computer experiments showed that the system starts its evolution thanks to nonlinear instability and reaches, within a few plasma periods, the exact nonlinear BGK equilibrium expected. (France)

59026 (CEA-CONF-1834) ELECTRON CORRELATIONS IN UNIFIED LINE SHAPES. Capes, H.; Voslamber, D. (Commissariat a l'Energie Atomique, Fontenay-aux-Roses (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-3). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

Electron correlations were introduced in the unified model for Stark broadening by electrons. (France)

59027 (IPP-6/94) ON THE VALIDITY OF THE QUASI-LINEAR APPROXIMATION FOR TURBULENT PLASMAS. Biskamp, D.; Welter, H. (Institut fuer Plasmaphysik, G.m.b.H., Garching (West Germany)). Mar 1971. 41p. Dep. NTIS (U. S. Sales Only).

Theoretical conditions for applicability of the quasi-linear theory (QLT) are formulated. To investigate the importance of these conditions, numerical experiments are performed on two different types of weak one-dimensional plasma instabilities. It is found that the behavior of the bump-in-tail instability is consistent with QLT (saturation field energy $\langle \hat{\mathcal{E}} \rangle / \gamma \pi n T \sim$ linear growth rate γ) if these conditions are satisfied, while in the opposite case, trapping stabilization is important (trapped particle bound frequency $\omega_b \sim \gamma$). The weak symmetric two-stream instability never satisfied the criterion for validity of QLT, since all particles that are supposed to diffuse are trapped ($\Delta v_{diff} \sim \Delta v_{trap}$). Incidentally, however, the first saturation level predicted by QLT is the same as given by the condition for trapping stabilization, $\omega_b \sim \gamma$. The important deviation in this case from weakly turbulent behavior is apparent from the coherent-mode coupling process, which becomes (relatively) stronger, the weaker the instability. (auth)

59028 RELAXATION OF DIFFERENCE BETWEEN ION AND ELECTRON TEMPERATURES IN A PLASMA. Aono, Osamu; Tange, Toshio (Tokyo Univ.). J. Phys. Soc. Jap.; 31: No. 4, 1234-6(Oct 1971).

The relaxation rate is obtained on the basis of the unified theory. When the ion temperature is of the same order of magnitude as the electron temperature, the effective screening length of the interaction is the electron Debye length. As the ion temperature decreases, the effective screening length decreases. The low ion-temperature asymptote is obtained. Numerical values are given graphically. (auth)

59029 VISCOSITY COEFFICIENTS OF A PLASMA IN A STRONG MAGNETIC FIELD: APPLICATION OF THE QUANTUM MECHANICAL UNIFIED THEORY. Kaneko, Shobu (Univ. of Tennessee, Knoxville). J. Phys. Soc. Jap.; 31: No. 4, 1240-5(Oct 1971).

The Coulomb logarithm for the viscosity coefficient of a plasma in a magnetic field is determined exactly by the quantum-mechanical unified theory. The magnetic field is assumed so strong that the condition, Debyelength ≪ ion gyration radius ≪ mean free path, is satisfied. For a hydrogenic plasma, the quantum correction to the Coulomb logarithm can not be neglected if the temperature is higher than 10^6 K. (auth)

59030 PENETRATION OF FAST HYDROGEN ATOMS INTO A FUSION REACTOR PLASMA. Riviere, A. C. (United Kingdom Atomic Energy Authority, Abingdon, Eng.). Nucl. Fusion; 11: No. 4, 363-9(Aug 1971).

The depth of penetration of fast hydrogen atoms into a fusion reactor plasma, before they become ionized and held by the magnetic field, is of importance in connection with the heating and refueling of such a plasma. Here, the experimental cross sections for the important collision processes are reviewed, and analytic expressions are formed that describe the data reasonably well. The ion and electron energy distributions to be expected in both toroidal and mirror reactors are used, with the analytic expressions for the cross sections, to calculate rate coefficients. The plasma thickness T for an 1/e reduction in intensity of the atom beam is then obtained as a function of beam energy and plasma temperature over the range 0.1 to 2000 keV (D^+, D^0). As an example, a 1-MeV deuterium atom beam entering a toroidal reactor plasma has $T = 1.7 \times 10^{16}$ and 2.5×10^{16} cm^{-2} for plasma temperatures of 1 and 100 keV, respectively. (auth)

59031 NEUTRAL-GAS ACCELERATION BY AN ELECTROMAGNETIC PLASMA GUN. Pert, G. J. (Univ. of Alberta, Edmonton). Nucl. Fusion; 11: No. 4, 371-5(Aug 1971).

It has recently been found (Pert, 1970) that an un-ionized shock wave is formed during the early discharge in a parallel-plate rail gun. Using this result it is possible to accelerate neutral gas to high velocities with a low ionization level. A system utilizing this principle is proposed to accelerate neutral gas to high velocity. An analysis of the proposed system is presented. (auth)

59032 FRANCK–CONDON PRINCIPLE AND BROADENING OF ISOLATED SPECTRAL LINES IN PLASMAS. Szudy, J. (Nicholas Copernicus Univ., Torun, Poland). Acta Phys. Pol.; A40: No. 3, 361-361-78(Sep 1971).

The role of the Franck–Condon principle in the description of the pressure broadening of isolated spectral lines is investigated on the basis of the Jabłoński theory. Expressions for the correlation function of this theory are derived both in the semiclassical approximation as well as in a general way. First it is shown that the quasi-static Margenau–Holtsmark theory of line broadening follows from that of Jabłoński in the asymptotic case of heavy perturbers when the classical form of the Franck–Condon principle can be applied. On the other hand, the results of quantum-mechanical impact theory of line broadening due to electrons are re-derived under assumptions analogous to those used in the theories of scattering processes. For the nonspherically symmetrical interactions, a general expression for the line shape is given that is in a close analogy with that derived on the basis of the resolvent operator technique. (auth)

59033 MEASUREMENTS OF COLLISION AND HEATING TIMES IN A TWO-DIMENSIONAL THERMAL COMPUTER PLASMA. Hockney, R. W. (IBM Watson Research Center, Yorktown Heights, N. Y.). J. Comput. Phys.; 8: No. 1, 19-44 (Aug 1971).

The nearest grid point (NGP) and the cloud in cell (CIC) particle models of a plasma were studied, together with two other models obtained from the above by smoothing the potential before use (HNGP and HCIC models). The collision time is found to be only slightly dependent on the model and is given to 20% by $(\tau_{coll}/\tau_{pe}) = n(\lambda_{D^2} + W^2)$, where n is the density and W the width of the particles (W = H, the mesh spacing for NGP and CIC; W = 2H for HNGP and HCIC). The ratio of electric-field energy to particle energy is given by $\langle \mathcal{E}^2 \rangle / 8\pi \div nmv_{th}^2 = 0.12/n(\lambda_{D^2} + W^2)$. Stochastic heating due to the finite size of the space mesh and the time step DT is correlated as a function of H/λ_D and $\omega_{pe}DT$. An optimum path in this parameter plane is found to be $(\omega_{pe}DT)_{opt} = \min[\tfrac{1}{2}H/\lambda_D, 1]$. On this path the ratio of the heating time (the time for the average kinetic energy of an electron to increase by $\tfrac{1}{2}kT$) to the collision time is $(\tau_H/\tau_{coll}) = K_2/(H/\lambda_D)^2$, where K_2 = 2.1(NGP), 6.4 (HNGP), 41 (CIC), 200 (HCIC). The models are compared on the basis of the cost in computer time per square collisionless plasma period per mesh cell. If we permit computing provided $(\tau_H/\tau_{coll}) > 10$ (or better than 2.5% energy conservation in a collision time) then the most economic model to use is given by the table: 0 ← NGP → 0.45 ← HNGP → 0.8 ← CIC → 2.0 ← HCIC → 4.5, where the name of the model is written between the values of H/λ_D for which it is best suited. Alternatively, if one accepts a model provided

$(\tau_H/\tau_{coll}) > 1$ (or better than 25% energy conservation in a collision time), then the favored ranges for the different models are $0 \leftarrow$ NGP $\rightarrow 1.5 \leftarrow$ HNGP $\rightarrow 2.5 \leftarrow$ CIC $\rightarrow 6.5 \leftarrow$ HCIC $\rightarrow 14$. None of the models considered may be used for $H/\lambda_D > 14$. (auth)

59034 DETERMINATION OF PARAMETERS OF NONEQUILIBRIUM PLASMA IN A RESTRICTED VOLUME ALLOWING FOR STEP-WISE IONIZATION. Gavryushenko, B. S.; Latyshev, L. A.; Chelnokov, M. B. Zh. Prikl. Spektrosk.; 14: No. 3, 389-92(Mar 1971). (In Russian).

The population of excited levels and the contribution of these levels in ionization were determined, allowing for a large number of elementary processes including photon absorption. A system of equations and their solution were obtained for a non-equilibrium, low-pressure plasma for a Maxwell electron distribution. The calculated results agree with experimental data. The maximum contribution in the ionization of cesium gives the level $6P_{1/2}$ over a broad range of plasma parameters. (tr-auth)

59035 CATHODE SHEATH IN A DISTRIBUTED MAGNETOPLASMA WITH INTERACTIONS BETWEEN PLASMA PARTICLES AND THE CATHODE. Minyatov, A. V.; Pankratov, V. G. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 583-8(Oct 1971).
Translated from Zh. Tekh. Fiz.; 41: No. 4, 744-51(Apr 1971).

A solution of Maxwell's equations for the electric field E is used to obtain a relationship between the electric field at the cathode surface, which enters into the Schottky correction to the Richardson formula, and the potential drop in the cathode sheath. A current balance equation is used to determine the voltage–current characteristics. Results of the computations are presented. (auth)

59036 RADIAL DISTRIBUTION OF RADIATION INTENSITY IN AXISYMMETRIC DENSE PLASMA. Ambrok, G. S. Zh. Prikl. Spektrosk.; 14: No. 3, 383-8(Mar 1971). (In Russian).

An analytical scaling method is proposed for approximating the transverse integral intensity distribution according to the radius in an axially symmetric dense plasma. The approximation is included in a substitute for the absorption coefficient, which becomes an integral equation of the first order, by its average value. The Laplace transform is used to solve the integral equation. For transparent media, the solution leads to a solution of Abel's equation, which holds valid for optical transparency of over 80%. For denser plasmas, a solution of the general equation is necessary. (tr-auth)

59037 NONLINEAR THEORY OF PLASMA MOTION IN A HIGH-FREQUENCY ELECTROMAGNETIC FIELD. Vas'kov, V. V.; Karpman, V. I. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 529-32(Oct 1971).
Translated from Zh. Tekh. Fiz.; 41: No. 4, 676-9(Apr 1971).

The nonlinear motion of a nonisothermal plasma is considered in a strong high-frequency electromagnetic field due to traveling TE waves. The general properties of solitary and periodic waves are investigated. (auth)

59038 INHERENT MAGNETIC FIELD IN THE POSITIVE COLUMN. Belousova, L. E. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 524-8(Oct 1971).
Translated from Zh. Tekh. Fiz.; 41: No. 4, 669-75(Apr 1971).

An approximate solution is obtained for the electron balance equation by means of Galerkin's method in a stationary positive column; account is taken of the inherent magnetic field for direct and stepwise ionization. The effect of the charged particle density at the boundary on the distribution curve is considered. An approximate solution is found which takes into account the inherent magnetic field and Coulomb collisions. An expresssion is obtained for the electron equilibrium distribution under the effect of the inherent magnetic field and Coulomb collisions. (auth)

59039 ANOMALOUSLY LARGE SCATTERING BY A TURBULENT, WEAKLY IONIZED PLASMA. Bugnolo, Dimitri S. Phys. Rev. Lett.; 27: No. 16, 1042-4(18 Oct 1971).

An anomalously large result is predicted in the first Born approximation for the scattering cross section of a turbulent, weakly ionized plasma for the case when $\omega > \omega_p$, $\nu_{en} > \omega_p$, and $\omega \sim \nu_{en}$. (auth)

59040 NUMERICAL INTEGRATION METHODS OF THE VLASOV EQUATION. Joyce, Glenn (Univ. of Iowa, Iowa City); Knorr, Georg; Meier, Homer K. Contract AT(11-1)-2059. J. Comput. Phys.; 8: No. 1, 53-63(Aug 1971).

The methods of integrating the nonlinear Vlasov equation are reviewed, compared, and interrelations are investigated. Another method is given that allows a truncation of the resulting infinite matrix without causing numerical instabilities. Its application to the linear and nonlinear Vlasov equation is discussed. It is shown that the cause for numerical instability is based on approximating a continuous eigenvalue spectrum by a discrete spectrum. (auth)

59041 APPLICATION OF THE GENERALIZED NEWTON–RAPHSON METHOD IN RADIATIVE-TRANSFER PROBLEMS. Skumanich, A.; Domenico, B. A. (National Center for Atmospheric Research, Boulder, Colo. Univ. of Colorado, Boulder). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 547-57(Jun 1971).
From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

The simultaneous excitation and transfer of radiation in a plasma gives rise to nonlinear operator equations for the atomic occupation numbers. An iterative method for solving such equations, based on a generalized Newton–Raphson scheme, is described and applied to the problem of the formation (under the condition of complete redistribution) for a resonance emission line interacting with two associated subsidiary lines (the three-level atom or ($L\alpha$, $L\beta$, $H\alpha$) problem). (auth) (UK)

59042 EFFECTIVE POTENTIALS BETWEEN THE COMPONENTS OF A HYDROGENEOUS PLASMA. Barker, A. A. (Univ. of Florida, Gainesville). J. Chem. Phys.; 55: No. 4, 1751-9(15 Aug 1971).

Two-particle "effective potentials," which incorporate the quantum mechanical effects into the pair interaction potential, are evaluated accurately. Tables and graphs of these potentials between electron–proton, parallel spin electron–electron, antiparallel spin electron–electron, and proton–proton are presented for a wide range of temperatures. The range of validity and analytic properties of the effective potentials in certain regions are given. Possible uses of these potentials to evaluate thermodynamic properties and percentage ionization of the plasma are discussed. (auth)

59043 DETONATION WAVES IN RELATIVISTIC MAGNETOHYDRODYNAMICS. Cissoko, M. Compt. Rend., Ser. A; 273: No. 1, 54-7(5 Jul 1971). (In French).

The Lichnerowicz formalism is applied to the study of the general properties of detonation waves in relativistic magnetohydrodynamics. The classical results are generalized in both general and special relativity. (France)

59044 HIGH-MACH-NUMBER TURBULENT MAGNETOSONIC SHOCKS. Papadopoulos, K.; Wagner, C. E.; Haber, I. (Naval Research Lab., Washington, D. C.). Phys. Rev. Lett.; 27: No. 15, 982-6(11 Oct 1971).

High-Mach-number turbulent magnetosonic shocks caused by driving a purely reflecting piston into a plasma were simulated using an electromagnetic particle code. A physical analysis of the results is presented, together with scaling arguments and comparisons with experimental data. (auth)

59045 BREMSSTRAHLUNG POWER DENSITY: SEMICLASSICAL CALCULATIONS. Modesitt, G. E. (Rand Corp., Santa Monica, Calif.). Phys. Rev. Lett.; 27: No. 15, 971-3(11 Oct 1971).

Quantum limitations on classical bremsstrahlung calculations are discussed. It is shown that the minimum impact parameter for low-energy ($\lesssim$13-Ev) electrons is $\sim(e^4\hbar/m^3v^5)^{1/3}$. Oppenheim's results, purporting to show that the power radiated in a plasma is greater than previously predicted, are explained and shown to be invalid. (auth)

59046 ELECTRICAL CONDUCTIVITY IN TOROIDAL PLASMA WITH TRAPPED PARTICLES. Daybelge, Umur (Massachusetts Inst. of Tech., Cambridge). Phys. Rev. Lett.; 27: No. 14, 916-19(4 Oct 1971).

The electrical conductivity in a toroidal plasma was calculated, using the exact Fokker–Planck operators for electron–electron and electron–ion collisions. It is found that the nonlinear effects of the electron–electron operator are of order r/R, where r and R are the minor and major radii of a flux surface. The conductivity can be written as $\sigma = \sigma_{Spitzer} [1 - \frac{3}{2}(r/R)^{1/2} + O(r/R)]$. (auth)

59047 MIXED THREE-DIMENSIONAL FLOWS OF GAS IN LONGITUDINAL MAGNETIC FIELDS. Gorskii, V. B. Zh. Prikl. Mekh. Tekh. Fiz.; No. 2, 34-7(Mar-Apr 1969). (In Russian).

Spatially mixed flows of gas with infinite conductivity in a longitudinal magnetic field are considered. By the method of small perturbations, approximate equations are found of the magnetic potential of velocity of perturbation for all of the possible mixed flows; also, certain special integrals were obtained. (tr-auth)

XUM

59048 STEADY-STATE DISTRIBUTION OF CHARGED PARTICLES IN THE DIFFUSION APPROACH. **Aleksandrov, A. F.; Ambaryan, S. S.; Mitsuk, V. E.; Pogosyan, V. A. Zh. Prikl. Mekh. Tekh. Fiz.; No. 2, 61-6(Mar-Apr 1969). (In Russian).**

The problem concerning the steady-state density distribution of charged particles in weakly ionized plasma is examined in the presence of processes of volumetric ionization, recombination, and diffusion in space-charge fields. The solution of balance equations of charged particles together with Poisson equations for the case of a plane, cylindrical configuration of plasma are obtained, satisfying the Schottky condition at the boundaries of the region. The solution of the problem is also found when the ionization process is localized in the spherically symmetric volume, and the Schottky condition is realized to infinity. The conditions for existence of the steady state and analysis are adduced. (tr-auth)

59049 EXPANSION IN VACUUM OF RAREFIED PLASMA WITH IONS OF TWO TYPES. **Gefter, V. M. Zh. Prikl. Mekh. Tekh. Fiz.; No. 1, 32-8(Jan-Feb 1970). (In Russian).**

One-dimensional expansion in the vacuum of multi-temperature plasmas with two varieties of ions was studied. In plasma with a Maxwellian ion velocity distribution, wave propagation at reduced pressure was noted, the boundary of which is a weak discontinuity that moves with the velocity of the ion sound in the plasma. The magnitude of this velocity was found. The first two moments of the distribution function were found. The approximate asymptotic solution of the system of transport equations was obtained in the case of closeness of mass of both varieties of ions; their numerical solution was done by computer. (tr-auth)

59050 DIELECTRIC PERMITTIVITY OF A WEAKLY IONIZED PLASMA PLACED IN CROSSED FIELDS. **Cristea, M. Stud. Univ. Babes-Bolyai, Ser. Phys.; 16: No. 1, 29-46(1971). (In Rumanian).**

The dielectric permittivity of a weakly ionized plasma situated in crossed fields $\vec{E}_0$ and $\vec{B}_0$ was determined. The homogeneous infinite plasma is described by an integral kinetic equation of the BGK collision type. Only the case in which the wave vector of the perturbation is located in the plane determined by the vectors $\vec{E}_0$ and $\vec{B}_0$ was studied. (tr-auth)

59051 APPROXIMATION METHOD OF CALCULATION OF THE BOUNDARY LAYER OF DUAL-TEMPERATURE PLASMAS ON ELECTRODES AT HIGHER VALUES OF THE HALL PARAMETER. **Kalikhman, L. E. Zh. Prikl. Mekh. Tekh. Fiz.; No. 1, 44-52(Jan-Feb 1970). (In Russian).**

Processes that occur in the boundary layer of plasma on electrodes are described by a complex system of differential equations with boundary conditions specified on two boundaries. Approximation methods for calculating boundary processes are discussed. (tr-auth)

59052 EIGENVALUE PROBLEMS FOR LAGRANGIAN SYSTEMS. V. **Barston, E. M. (New York Univ., N. Y.). J. Math. Phys. (N. Y.); 12: No. 9, 1867-72(Sep 1971).**

Sufficient conditions for exponential instability are obtained for a class of infinite-dimensional gyroscopic Lagrangian systems. Applications are made to the problems of the stability of a rotating thin annular elastic disk and the stability of the steady flow of a one-dimensional warm electron plasma. (auth)

59053 POLYNOMIAL EXPANSION METHOD FOR PROBLEMS INVOLVING A RELATIVISTIC MAXWELLIAN DISTRIBUTION. **Nishimura, Keiichi (Univ. of California, Livermore). J. Math. Phys. (N. Y.); 12: No. 9, 1840-5(Sep 1971).**

With the aim of extending the Sonine polynomial expansion method to the region of relativistic Maxwellian distribution functions, a new set of polynomials is introduced in terms of their orthogonality equation. Their coefficients are derived and tabulated as functions of the temperature for several lower orders. (auth)

Production

59054 (MATT-782) USE OF LONG-WAVELENGTH, HIGH-POWERED LASERS FOR CONTROLLED THERMONUCLEAR FUSION. **Dawson, J. M.; Kidder, R. E.; Hertzberg, A. (Princeton Univ., N. J. Plasma Physics Lab.). Sep 1971. Contract AT(30-1)-1238. 38p. Dep. NTIS.**

The possibilities for applying low-frequency lasers, in particular the 10-μ CO_2 laser, to the problem of controlled thermonuclear reaction are discussed. The 10-μ CO_2 laser can be effective for heating plasmas in the density range of 10^{17} to 10^{19} up to a temperature of several keV. If enough passes of the beam through the plasma can be achieved, effective heating at densities as low as 10^{16} might occur. The development of powerful lasers for 100-μ radiation would make this a definite possibility. It appears that such a laser is a very versatile tool for producing plasma, and many possible plasma configurations can be evisioned. A number of possible fusion devices are presented. These merely represent examples of what might be considered, and are intended to give some feeling for what is possible. Possibilities both for full-scale working reactors and for doing significant experiments today are discussed. (auth)

59055 PRODUCTION OF A VERY QUIESCENT PLASMA IN SKIPPING MAGNETIC FIELDS. **Goede, A.; Brakenhoff, G. J.; Hopman, H. J.; Massmann, P. (FOM-Instituut voor Atoom-en Molecuulfysica, Amsterdam). Phys. Rev. Lett.; 27: No. 16, 1044-7(18 Oct 1971).**

A very quiescent helium plasma, with density fluctuations of less than 0.2%, is produced by applying the stabilizing field of permanent magnets. The steady-state plasma column created in this field, which is of the average minimum-B type, not only proves to be extremely quiescent but also has a homogeneous density distribution in the axial direction ($\Delta n/n\Delta z \approx 2 \times 10^{-3}$ cm^{-1}). The plasma has a density of 5×10^{10} cm^{-3}; the electron temperature is about 7 eV. (auth)

59056 HIGH DENSITY θ-PINCH PLASMA PRE-IONIZED BY THE SHOCK WAVE. **Takeda, Susumu; Funahashi, Akimasa; Kando, Masashi; Makihira, Tsuneichi (Nagoya Univ., Japan). Jap. J. Appl. Phys.; 10: No. 10, 1470(Oct 1971).**

Radio-frequency discharges and shock waves for pre-ionization of a theta-pinch plasma were compared. Diagrams showing the results are given. (M.O.W.)

59057 LASER LIGHT FOR FUSION FIRE. **Basov, Nilolai; Krokhin, Oleg (Lebedev Inst. of Physics, Moscow). New Sci. Sci. J.; 51: No. 771, 733-4(30 Sep 1971).**

Pulsed thermonuclear reactors would remove some of the containment problems of continuous reactors, but such devices need powerful pulsed heating systems. High-power lasers may be ideal for this. Soviet scientists claim to have already achieved laser-induced fusion in a plasma. (UK)

59058 APPLICATIONS OF LASER-PRODUCED PLASMA TO CONTROLLED THERMONUCLEAR FUSION. **Martellucci, S. (Laboratori Gas Ionizzati, Frascati, Italy). Energ. Nucl. (Milan); 18: No. 10, 541-54(Oct 1971).**

Applications of lasers to controlled thermonuclear fusion are reviewed, along with practical feasibility considerations. The physical processes of plasma ionization, heating, and dynamics are described, and particular emphasis is given to plasma production by lasers from solid materials. The conditions for obtaining a pulsed fusion reactor of unitary efficiency are defined as a function of energy and time emission characteristics of the laser source; the requirements for such a source in order to trigger the propagation of the thermonuclear reaction process into a fusionable material are also given. Finally, the present and prospective research programs in Italy and abroad are mentioned. (auth)

59059 CALCULATION OF THE CHARACTERISTICS OF STABILIZED ELECTRIC ARC HEATING OF GASES AT HIGH PRESSURES. **Suksov, I. I.; Levin, M. P. Izv. Sib. Otd. Akad. Nauk SSSR, Ser. Tekh. Nauk; No. 13, 100-5(Oct 1969). (In Russian).**

During electric-arc heating of gases in plasmatrons, the role of radiation increases strongly with increased pressure. This complicates the cooling of electrodes in experiments, and difficulties appear in theoretical results (from complexity of mechanism of radiation transport) associated with calculation of the fraction of radiation in the overall energy balance. Here, relationships are adduced for calculation by the method of successive approximations of electric and thermal characteristics during stabilized (asymptotic) heating of gas from electric arc columns in spherical channels, with radiation calculations. A simplified method is proposed for estimating the effect of radiation on the basis of data on the degree of blackness of plane-parallel layers or hemispherical volumes. Calculational results for air are given. (tr-auth)

59060 (CEA-CONF-1800) DISSIPATIVE INSTABILITY ASSOCIATED WITH ELECTRONS TRAPPED IN TOKAMAK-TYPE CONFIGURATIONS. Adam, J. C.; Laval, G.; Pellat, R. (Commissariat a l'Energie Atomique, Fontenay-aux-Roses (France). Centre d'Etudes Nucleaires). [1971]. 3p. (In French). (CONF-710527-1). Dep. NTIS (U. S. Sales Only).

From Physics conference; Evian, France (25 May 1971).

The influence of collisions on a localized instability due to trapped electrons in a toroidal configuration is studied. It is assumed that the frequency of the instability is greater than the ion bounce frequency but lower than the electron frequency. (auth)

59061 (CEA-CONF-1828) ELECTROSTATIC INSTABILITIES IN A TWO-COMPONENT ANISOTROPIC PLASMA. Jacquinot, J.; Leloup, C. (Commissariat a l'Energie Atomique, Fontenay-aux-Roses (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-8). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

Anisotropy driven electrostatic instabilities near the electron cyclotron frequency and its harmonics seem to play an important role in hot electron plasmas confined in a mirror geometry. In all the experiments that exhibit this instability, a cold plasma coexists with the hot population, the ratio of the cold to the hot densities varying between 1 and 100. The growth rate and marginal stability conditions were calculated, taking into account the cold plasma effects. Numerical solutions are given for an anisotropy ratio $\theta = 8$. (France)

59062 (IPP-6/97) ASYMPTOTIC BEHAVIOR OF THE TWO-STREAM INSTABILITY. Biskamp, D.; Chodura, R. (Institut fuer Plasmaphysik, G.m.b.H., Garching (West Germany)). Jun 1971. 15p. Dep. NTIS (U. S. Sales Only).

Some theoretical ideas are investigated to better understand the results of numerical simulations of the one-dimensional two-stream instability. The observed relation $v_{drift} = v_{the}$ implies a principle of maximum dissipation. On a microscopic level it is shown that the quasi-linear solution is inconsistent with $v_{drift} = v_{the}$, and the assumption of an adiabatically growing BGK wave can not explain the observed similarity behavior. It is proposed that the anomalous resistivity be due to an instability of a BGK wave. Speculations on the multi-dimensional case are made in connection with preliminary results of two-dimensional computations. (auth)

59063 (NP-19031) HIGH-FREQUENCY RESONANT PLASMA. Moisan, M. (Paris Univ., Orsay (France). Laboratoire de Physique des Plasmas). May 1971. 111p. (In French). (LP-130). Dep. NTIS (U. S. Sales Only).

A new type of high-frequency plasma is described that is particularly well adapted to the experimental demonstration of the parametric instabilities predicted by V.P. Silin, Yu. M. Aliev, and E. Ferlenghi and also Nishikawa, Dubois, and Goldman. Extremely intense high-frequency fields are developed within the plasma. The parameters ν_m, T_e, and E^2/T_e, which play an important role in the instability mechanism are evaluated theoretically. The experimental arrangement and the properties of the plasma over its operating regions are described in detail. It is shown that the behavior of the high-frequency plasma can be clearly interpreted on the basis of plasma resonances. (France)

59064 STABILITY OF RELATIVISTIC PLASMA. Ikuta, Kazunari (Nagoya Univ., Japan). J. Phys. Soc. Jap.; 31: No. 4, 1232-3(Oct 1971).

The $\delta\int dl(1/B)$ criterion of the plasma stability is extended to the relativistic plasma. The relativistic plasma is stable for the interchange instability if $\int(\delta B/B^2)(\Pi_{||} + \Pi_{\perp})dl > 0$, where $\Pi_{||}$ and $\Pi_{\perp}$ are the anisotropic pressure of the relativistic plasma along and perpendicular to the magnetic line of force, respectively. (auth)

59065 ORDINARY-MODE ELECTROMAGNETIC INSTABILITY IN COLLIDING PLASMA STREAMS. Lee, Kai Fong; Armstrong, James C. (Catholic Univ. of America, Washington, D. C.). Phys. Rev., A; 4: No. 5, 2087-94(Nov 1971).

The instability of the electromagnetic linearly polarized mode propagating perpendicular to the magnetic field is studied for a system composed of two colliding plasma streams, in each of which both the electrons and the ions are streaming at the same velocity. Based on the linearized Vlasov–Maxwell equations and allowing for anisotropic temperatures, it is found that in the presence of streaming ions the instability can occur in very low-β plasmas. The higher the values of β, the streaming velocity, and the temperature ratios $T_{||e}/T_{\perp e}$ and $T_{\perp e}/T_{\perp i}$, the more the plasma is susceptible to the electromagnetic instability. The ratio $T_{||i}/T_{||e}$ has negligible influence, except when the streaming velocity is smaller than the ion thermal speed. It is found that for β values of order unity, the streaming ions, while greatly enlarging the range of unstable wave numbers, contribute negligibly to the maximum growth rate, which is typically of the order of the electron cyclotron frequency. A comparison with the growth rates of the electrostatic two-stream instability is made. (auth)

59066 MAGNETOHYDRODYNAMIC INSTABILITIES IN A WEAKLY IONIZED, RADIATING PLASMA. Hougen, Merritt L.; McCune, James E. (Massachusetts Inst. of Tech., Cambridge). AIAA (Amer. Inst. Aeronaut. Astronaut.) J.; 9: No. 10, 1947-56 (Oct 1971).

A unified, linear theory is formulated for MHD waves at low magnetic Reynolds number, propagating transverse to the magnetic field in a weakly ionized, radiating plasma. The set of equations obtained from a two-fluid model yields a fifth-order dispersion relation whose roots correspond to four waves: magneto-acoustic (a paired wave), thermal, electrothermal, and "ionization-rate." To bring out the physics of each of these waves, simplifying assumptions are made, and "simple" analytical wave solutions are found. By taking advantage of the wide separation of the roots in the complex plane, "distinct" wave solutions are obtained in which many limitations of the "simple" wave solutions are absent and which are in excellent agreement with the roots of the full dispersion relation, obtained numerically. Both thermal and magneto-acoustic waves are shown to require a two-fluid model for proper description. In particular, the latter mode requires the inclusion of the rate of change of electron enthalpy for wavelengths ≤ 0.1 m at typical MHD generator conditions. The electrothermal wave instability region is much larger than previously thought, whereas the "ionization rate wave" is always stable. (auth)

59067 HIGH-FREQUENCY ELECTROSTATIC PLASMA INSTABILITIES. Freidberg, J. P.; Marder, B. M. (Los Alamos Scientific Lab., N. Mex.). Phys. Rev., A; 4: No. 4, 1549-53 (Oct 1971).

A description of the stability properties of a plasma under the influence of an external electric field oscillating near the plasma frequency is presented. (auth)

59068 KINKS AND TEARING MODES IN SIMPLE CONFIGURATIONS. Goedbloed, J. P.; Dagazian, R. Y. (International Centre for Theoretical Physics, Trieste, Italy). Phys. Rev., A; 4: No. 4, 1554-60(Oct 1971).

A plane slab of current-carrying plasma is generally shown to be stable against ideal magnetohydrodynamical modes. It is shown that some of the stability criteria appearing in the literature and contradicting this fact can be brought to bear on the stability of the tearing mode. In this connection, simple stability diagrams are shown for the tearing mode in plane and cylindrically symmetric force-free magnetic fields. (auth)

59069 LOW-FREQUENCY INSTABILITIES IN MAGNETIC PULSES. Krall, Nicholas A.; Liewer, Paulett C. (Univ. of Maryland, College Park). Phys. Rev., A; 4: No. 5, 2094-2103 (Nov 1971).

Electrons drifting relative to ions across a magnetic field are found to drive a set of intermediate-frequency long-wavelength waves ($\omega_{ci} < \omega < \omega_{ce}$) unstable for any temperature ratio T_e/T_i. One instability is caused by the coupling of a drift wave in a nonuniform plasma to either the ion plasma oscillation or a lower hybrid oscillation, depending on density and field strength. Another instability is a form of the two-stream instability, shown here to exist even for drift speeds less than electron thermal speeds. Growth rates are on the order of the ion plasma (or lower hybrid) frequency, depending on the density and field strength. (auth)

59070 ION-CYCLOTRON DRIFT INSTABILITY IN A FINITE-β PLASMA. Mikhailovskii, A. B. (Inst. of Atomic Energy, Moscow). Nucl. Fusion; 11: No. 4, 323-7(Aug 1971).

The possibility of the buildup of ion-cyclotron perturbations in an inhomogeneous plasma having a finite ratio between its pressure and the pressure of a magnetic field is investigated. It is shown that the plasma is more stable with respect to such perturbations at finite pressure than at zero pressure. The stabilization is associated with a smearing of the cyclotron resonance resulting from the velocity dependence of the magnetic drift of the ions; it is also linked with Landau damping in the electrons, the magnetic drift of which coincides with the wave phase velocity. (auth)

59071 DYNAMIC STABILIZATION OF THIN PLASMA FILAMENTS. Nikulin, M. G. Zh. Prikl. Mekh. Tekh. Fiz.; No. 1, 24-31(Jan-Feb 1970). (In Russian).

The Routh function was found for thin plasma filaments (toroidal

XUM

and linear), testing smooth long-wave perturbations of spiral or constricted type for the case when the external magnetic field is a combination of quadrupole and longitudinal fields. The different variants of dynamic stabilization of the filament are briefly discussed. The combining of dynamic stabilization of linear jets with variable current stabilized by quadrupole and longitudinal fields is studied. (tr-auth)

59072 LOW-FREQUENCY WAVES AND INSTABILITIES IN A MAGNETOPLASMA. Duncan, A. J.; Forrest, J. R. (Stanford Univ., Calif.). pp 389-93 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

Instabilities arising in the positive column of a low-pressure gas discharge are discussed, together with means to avoid or suppress them, and a simplified theory of low-frequency wave propagation for a plasma in a uniform magnetic field is presented that predicts observed wave modes and their propagation characteristics. The theory is applicable to frequencies <1 MHz, neutral gas pressures <1 torr, and magnetic fields up to several hundred gauss. A novel feature of the theory is its description of ionization wave propagation in a magnetic field; little experimental data exist for this and, for this reason, propagation experiments were carried out with a He discharge. Comparisons are made between theory and experiment, and agreement was found to be good. Ionization waves are predicted by the theory and shown to be perturbations that, with increasing magnetic field or neutral gas pressure, give rise to instabilities. (UK)

Thermonuclear Processes

59073 (GULF-GA-A-10807) CONTROLLED THERMONUCLEAR RESEARCH PROGRAM. Summary Progress Report, August 1, 1970–July 31, 1971. Ohkawa, Tihiro (Gulf General Atomic Co., San Diego, Calif.). 15 Sep 1971. Contract AT-(04-3)-167 91p Dep. NTIS.

The discussion of the dc multipole is divided into 5 subsections: (1) review of the device and its performance characteristics, (2) classical diffusion at high densities, (3) loss mechanisms at low densities, (4) design criteria and construction of the new toroidal winding, and (5) preliminary experiments with combined poloidal and toroidal magnetic fields. Research on Doublet II is discussed in four subsections: (1) vacuum system, (2) the field shaper, (3) the E-coil system, and (4) the B-coil system. (M.O.W.)

59074 (IPP-1/119) VACUUM MAGNETIC FIELDS OF LINEAR STELLARATORS WITH SHAPED COILS. Lehner, G.; Pohl, F. (Institut fuer Plasmaphysik, G.m.b.H., Garching (West Germany)). Jul 1971. 14p. Dep. NTIS (U. S. Sales Only).

The vacuum magnetic fields of linear stellarators with shaped coils are discussed. Two types of expansions are given. The fast one is valid for sufficiently slender coils and the second one for coils with a sufficiently small helical deviation. Some numerical results are described also and compared with the results of the approximations. (auth)

59075 (ORNL-TM-3593) PROPOSAL FOR COMPUTER ASSISTED DATA ACQUISITION FOR ORNL FUSION EXPERIMENTS. Betz, N.; Dory, R. A.; Francis, J. E.; Yonts, O. C. (Oak Ridge National Lab., Tenn.). Oct 1971. Contract W-7405-eng-26. 29p. Dep. NTIS.

Relatively small, inexpensive computers can provide improved efficiency and reliability for data taking and extend the range of feasible studies. The principal reasons for this are: (1) rapid data sampling with readily varied sampling procedures; (2) archival storage of machine parameters for later analysis; (3) real-time data analysis for determining parameters to be used later (time ~ minutes); (4) preparation of raw experimental data for large-scale analysis at the ORNL computer center (time ~ hours); and (5) possible direct control by computer program of some of the parameters (time ~ milliseconds). (auth)

59076 (UCRL-Trans-10556) INVESTIGATION OF THE LASER INITIATED DISCHARGE SPARK CHANNEL. Zorev, N. N.; Sklizkov, G. V.; Fedotov, S. I.; Shikanov, A. S. (Akademiya Nauk SSSR, Moscow. Institut Fiziki). Translated for Univ. of California, Lawrence Livermore Lab., from Preprint No. 56. 20p. Dep. NTIS.

Experimental measurements were made of the delay time as a function of laser energy, laser beam focus location, electrode spacing, and pressure. The high-speed schlieren method was used in the experiments. The expansion velocity of the spark channel was measured, and the analysis of gasdynamic processes occurring in the gap for the case of various regimes was considered. The results of an approximate calculation of a discharge scheme are in agreement with experimental data. Minimum risetime was evaluated. It was shown that the use of laser methods to commute discharge gaps makes it possible to form light pulses having duration less than 100 psec. (auth)

59077 EFFECT OF EQUILIBRATING MAGNETIC FIELD ON PLASMA CROSS SECTION. Zakharov, L. E. Sov. Phys. Tech. Phys. (Engl. Transl.); 16: No. 4, 645-6(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 823-4(Apr 19711)).

A study was made of equilibrium in an axisymmetric plasma annulus of elliptical cross section. A uniform current distribution is assumed. The relationship between the decay index of the equilibrating magnetic field and the ratio of the semiaxis of the cross section was found. It is shown that deviations of the field from uniformity have very little effect on the shape of the cross section. (M.O.W.)

59078 FUSION REACTIONS IN SELF-COLLIDING ORBITS. Maglic, Bogdan C. (Rutgers–The State Univ., New Brunswick, N. J.); Blewett, John P.; Colleraine, Anthony P.; Harrison, W. Craig. Phys. Rev. Lett.; 27: No. 14, 909-12(4 Oct 1971).

A principle for a small nonplasma fusion device is proposed. Energetic ions are injected through the center of a Precetron-type magnetic field. An organized non-Maxwellian mixture ("migma") of particles having a central high-density region results. The collisions are predominantly head-on and Coulomb scattering effects significantly reduced. It is shown that the device can become critical, although, in the examples considered here, only at microwatt levels. (auth)

59079 TORUS DEVICE FOR THERMONUCLEAR FUSION EQUIPMENT: JFT-1. Kazawa, Yoshiaki; Wase, Keizo; Hashimoto, Hiroshi (Hitachi Ltd., Ibaraki, Japan). Hitachi Hyoron; 53: No. 4, 333-9(Apr 1971). (In Japanese)

A torus device "JFT-1" was constructed. The device is composed of internal conductor coils and toroidal coils. Plasma was confined stably with the internal coils, and more stability was obtained with help of the toroidal magnetic field. The internal coils consist of a HC-1 coil (183 KAT), a pair of HC-2 coils (95 KAT) and a pair of auxiliary coils (70 KAT), and excited by a 130 KJ, 3 KV condenser power source with a time interval of 1 min. Investigations of electromagnetic forces due to the coils were carried out. (Japan)

59080 HIGH-CURRENT HOLLOW-CATHODE ION SOURCES. Zeyfang, E. (DFVLR, Stuttgart). pp 251-5 of Gas Discharges. London; Institution of Electrical Engineers (1970).

From International conference on gas discharges; London, England (15 Sep 1970). See CONF-700969.

Development work on ion sources for Hall Ion Thrusters (HIT) is described. In this type of ion accelerator there is no limitation of current density, since the space charge in the accelerating region is neutralized. This is accomplished by using an annular accelerator channel with a magnetic field perpendicular to the electric accelerating field; the magnetic field traps the electrons within the accelerator channel and permits acceleration of the ions within a neutralized plasma. It is necessary for efficient operation of HITs to produce the ions outside the accelerator channel, and for this reason development work is being undertaken on ion sources for HITs operated with Ar and Hg. (UK)

59081 (AEC-tr-7272) CHARACTERISTICS OF COLLISIONLESS DAMPING OF ELECTROMAGNETIC WAVE IN A REGION OF INTENSE INHOMOGENEITY OF A COLD PLASMA. Dolgopolov, V. V.; Omel'chenko, A. Ya. (Akademiya Nauk Ukrainskoi SSR, Kharkov. Fiziko-Tekhnicheskii Institut). Translation of report KHFTI-69-53. 17p. Dep. NTIS.

The electromagnetic oscillations caused by initial perturbations were studied at the boundary of a semi-infinite plasma with a vacuum with allowance for finiteness of transition region from a homogeneous plasma to the vacuum, and also in an inhomogeneous plane-parallel layer of plasma in the case when the length of a wave propagating along the layer is appreciably greater than the layer's width. It was demonstrated that the surface waves caused by an initial perturbation, in a time interval determined by the width of the region in the inhomogeneous medium, convert fully to Langmuir-type oscillations, occurring along the direction of plasma density gradient and concentrated in the vicinity of the plasma resonance point. This vicinity forms a small part of the region of the plasma's inhomogeneity. If the width of the medium's inhomogeneity region is comparable with the wave length, in general the oscillations having the same frequency in various points of an inhomogeneous medium, do not exist. In a general case (at arbitrary relationship between wave length and typical dimension of inhomogeneity) as a result of the development of initial perturbation in plasma, the Langmuir oscillations will remain (their frequency differs at various points of an inhomogeneous medium); the effective wave vector of these oscillations in the direction of the plasma's density gradient increases without limit through time. (auth)

59082 (CEA-CONF-1803) LINEAR CONVERSION OF WAVES FOR AN OBLIQUE INCIDENCE. Fichet, M.; Fidone, I.; Granata, G. (Commissariat a l'Energie Atomique, Fontenay-aux-Roses (France). Centre d'Etudes Nucleaires). [1971]. 2p. (In French). (CONF-710527-3). Dep. NTIS (U. S. Sales Only).

From Physics conference; Evian, France (25 May 1971).

Linear conversion of waves at the upper hybrid resonance for oblique propagation is considered. The conditions for the validity of a fourth-order equation near the resonance are discussed. (France)

59083 (CEA-CONF-1826) DIELECTRIC PROPERTIES OF PLASMA PENETRATED BY THE HELICON WAVE AND ITS INFLUENCE ON MICROINSTABILITIES IN THE CASE OF ANISOTROPIC ION TEMPERATURES. Teichmann, J. (Commissariat a l'Energie Atomique, Grenoble (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-10). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

The influence of the helicon wave upon several kinds of microinstabilities has been discovered recently. The effect observed is due to the particular properties of the plasma hf field system. The changes observed in the plasma dielectric properties when submitted to a strong hf field were studied. Only microinstabilities generated by the anisotropy of the ion temperature were considered. (France)

59084 (CEA-CONF-1827) LOWER-HYBRID WAVE-PLASMA INTERACTION. Pesic, S. S. (Commissariat a l'Energie Atomique, Grenoble (France). Centre d'Etudes Nucleaires). [1971]. 4p. (CONF-710920-9). Dep. NTIS (U. S. Sales Only).

From tenth international conference on phenomena in ionized gases; Oxford, England (13 Sep 1971).

In order to estimate the role of the boundedness of laboratory plasmas in wave energy transfers, the interaction between obliquely incident electromagnetic waves and a nonuniform plasma column confined in an axial static magnetic field was analyzed. The influence of the particle thermal motion on the wave absorption by the cold plasma was investigated. (France)

59085 STATIONARY SIMPLE WAVES IN A PLASMA AT ANISOTROPIC PRESSURE. Kartalev, M. D. Izv. Akad. Nauk SSSR, Mekh. Zhidk. Gaza; No. 2, 12-19(Mar-Apr 1971). (In Russian).

The character of stationary, simple waves in a plasma at anisotropic pressure is investigated, using the hydrodynamic equation of Chew, Goldberger, and Low. When the average current velocity vectors and the magnetic field intensity are parallel, the system of equations converges to two quasi-linear equations for a velocity component. For an assumed hyperbolic character of this system, a characteristic set of equations is obtained. The character of simple waves flowing around various contours is examined. In a third part of the article the change in current parameters is qualitatively discussed. The fourth part is concerned with the possible transition of the plasma into an unsteady state. (tr-auth)

59086 WEAK NONLINEAR MAGNETO-ACOUSTIC WAVES IN AN INHOMOGENEOUS PLASMA. Kakutani, Tsunehiko (Kyoto Univ.). J. Phys. Soc. Jap.; 31: No. 4, 1246-8(Oct 1971).

Effect of inhomogeneity in plasma density and magnetic field on the propagation of magneto-acoustic waves in a cold collision-free plasma is investigated. It is shown, by using a nonlinear perturbation method, that the basic system of equations governing one-dimensional plane waves with small but finite amplitude can be reduced to a modified form of the Korteweg–de Vries equation, from which one can expect damping, growing, or splitting of the waves. (auth)

59087 EXACT TEST-PARTICLE PROPAGATOR OF THE LENARD-BERNSTEIN EQUATION FOR A MAGNETOPLASMA AND ITS APPLICATION TO THE TRANSVERSE-PLASMA ECHOES. Furutani, Y. (Faculte des Sciences, Orsay, France. Univ., Paris). Phys. Rev., B: 4: No. 4, 1577-83(Oct 1971).

An exact test-particle propagator of the Lenard–Bernstein equation in the presence of an external magnetic field is obtained as a generalization of the well-known bivariate Gaussian distribution given by Chandrasekhar. This propagator is applied to the problem of temporal transverse-plasma echoes. The free-particle model used here can predict a transverse echo when one of the two external signals is transverse and the other longitudinal. When both of two external excitations are transverse, it does not explain a plasma-wave echo, unless velocity increments of particles along the external magnetic field are explicitly given as a function of their transverse energy increments. The reason is that transverse velocity increments can not properly account for the circularly polarized nature of exciting signals. (auth)

59088 WAVE ABSORPTION IN A MAGNETOACTIVE PLASMA WITH SMALL TRANSVERSE DIMENSIONS. Fedorov, V. I. (Leningrad Polytechnic Inst.). Sov. Phys. Tech. Phys. (Engl. Transl.); 16: No. 4, 533-7(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 680-6(Apr 1971).

Solutions are obtained for the wave equation for a cylindrical column of a cold, magnetoactive plasma of small radius for the approximation that the electron density in the plasma is a parabolic function of the radius. This solution is used to compute damping constants for circular and rectangular waveguides containing cylindrical plasma tubes. (auth)

59089 EDGE EFFECTS IN EXCITATION OF MAGNETO-ACOUSTIC WAVES IN PLASMA. Balakhanov, V. Ya. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 517-23(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 660-8(Apr 1971).

The excitation of magnetoacoustic waves in an infinite cylindrical plasma column is discussed. It is found that the field in the plasma is composed of the sum of the direct and oblique waves and that the oblique wave is a standing wave fixed with respect to the edge of the coil. The total field in the vicinity of the edge of the coil depends on the excitation frequency and is a complicated function of the plasma parameters. Experimental observations of the excitations of magnetoacoustic waves in the plasma can be used to determine the dissipation of the field in the plasma and the components of the dielectric tensor. The results are presented in the form of an analytic solution in a rapidly converging series. (auth)

59090 NONSTATIONARY WEAKLY NONLINEAR WAVES THAT PROPAGATE AT AN ANGLE TO THE MAGNETIC FIELD IN A MULTICOMPONENT COLD PLASMA. Pataraya, A. D. (Inst. of Physics, Tbilisi, USSR). Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 515-6(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 657-9(Apr 1971).

Nonstationary, weakly nonlinear waves that propagate at an angle to the magnetic field in a multicomponent quasineutral fully-ionized cold plasma were investigated. The perturbed plasma variables satisfy an equation similar to one found for weakly modulated waves in nonlinear optics. (auth)

59091 MICROWAVE ABSORPTION BY A PLASMA AT THE UPPER HYBRID FREQUENCY. Anisimov, A. I.; Vinogradov, N. I.; Golant, V. E.; Pakhomov, L. P. (Ioffe Inst. of Physics and Tech., Leningrad). Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 546-9(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 696-700(Apr 1971).

It was shown earlier that a collisionless plasma has a linear absorption mechanism due to transformation of electromagnetic waves to plasma waves. The region in which microwave absorption occurs when transformation is possible was investigated. The experiments were performed in a toroidal magnetic field, in which the plasma parameters are uniform along the field under appropriate conditions. (M.O.W.)

59092 SURFACE WAVES IN A MAGNETIZED PLASMA. Kotsarenko, N. Ya.; Sinkevich, E. L.; Fedorchenko, A. M. (Kiev State Univ.). Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 640-1(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 818-20(Apr 1971).

The dispersion relation is obtained for surface waves propagating along a planar vacuum–plasma boundary at an arbitrary angle θ to a magnetic field parallel to the boundary. It is shown that (except for $\theta = \pi/2$) the waves are generalized surface waves, i.e., the attenuation within the plasma is of an oscillatory nature. (auth)

59093 LOW-FREQUENCY WAVES IN DENSE PLASMA CONTAINING TWO ION SPECIES. Chechkin, V. V. Sov. Phys. Tech. Phys. (Engl. Transl.); 16: No. 4, 637-9(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 815-17(Apr 1971).

The interaction of alfven and magnetoacoustic waves with a two-component plasma is discussed. In particular, the reflection and transmission properties are examined. (M.O.W.)

59094 PROPAGATION OF LARGE-AMPLITUDE TM WAVES IN A MAGNETOACTIVE PLASMA. Demchenko, V. V.; Dolgopolov, V. V. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 661-3 (Oct 1971).

XUM

Translated from Zh. Tekh. Fiz.; 41: No. 4, 839-40(Apr 1971).

Propagation of electric electromagnetic modes along a magnetoactive plasma is examined in the case in which there is a strong nonvarying magnetic field (with gyrofrequencies much greater than the corresponding plasma frequencies and wave frequency) transverse to the layer and the pressure of the electromagnetic field of the mode is much greater than the gas-kinetic pressure of the plasma. A dispersion equation containing no amplitude or temperature terms is derived in the large-amplitude approximation. An equation is found for the plasma density of a layer of varying thickness. The plasma density distribution is also independent of the wave amplitude and plasma temperature. (auth)

59095 ION WAVES EXCITED BY A GRID IN A COLLISIONLESS PLASMA. Gresillon, D. (Ecole Polytechnique, Paris). J. Phys. (Paris); 32: No. 4, 269-82(Apr 1971). (In French).

A theoretical and experimental study of ion dynamics in longitudinal ion waves in single-ended collisionless Q machine plasma is presented. The theory gives special attention to the properties of the first Landau pole and to the grid excitation mechanism. The latter allows the calculation of the excitation coefficients of the normal modes and the development of the first-order ion distribution function f_1. The experiments show dispersion of ion waves, and the collisionless damping is measured. These aspects are discussed in connection with the simultaneous measurement of the stationary ion distribution f_0. Finally, attention is directed towards the measurement of f_1, and preliminary results are presented. (France)

59096 RESONANT INTERACTION OF CHARGED PARTICLES WITH A CYCLOTRON WAVE. Kovtoune, R. I. (CEN, Fontenay-aux-Roses, France). J. Phys. (Paris); 32: No. 4, 283-93(Apr 1971). (In French).

The resonant interaction of charged particles with a cyclotron wave is discussed in a case where the wave propagates in a boundless plasma along a strong uniform magnetic field. Particle motion is studied with the help of the asymptotic method where the amplitude of a relative perturbation of the uniform magnetic field by the wave is used as a small parameter. Explicit expressions are found for the time dependence of particle longitudinal and transversal velocities, the latter being always finite contrary to predictions of the linear theory where longitudinal velocity variations are neglected. It is shown that the solutions obtained are reduced to those given by the linear theory, when the difference between cyclotron and Doppler-shifted wave frequency becomes large. (France)

59097 INFLUENCE OF SPATIAL DISPERSION ON THE COEFFICIENT OF SPONTANEOUS EMISSION OF CYCLOTRON RADIATION IN A NONEQUILIBRIUM PLASMA. Jahn, Herbert (Zentralinstitut fuer Solar-Terrestrische Physik, Berlin). Astrophys. Space Sci.; 12: No. 1, 34-9(Jul 1971).

The coefficient of spontaneous emission of cyclotron radiation propagating in the direction of an external magnetic field in nonequilibrium plasma was calculated, including the effect of spatial dispersion on the emission process. The resulting part of the emission coefficient may become important in the vicinity of the cyclotron frequency. (auth)

59098 INTERACTION BETWEEN ION–ACOUSTIC WAVES AND IONIZATION WAVES. Franklin, R. N. (Oxford Univ.). pp 563-73 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

A brief theoretical treatment of ion waves and ionization waves in discharges is given. Some experimental data showing these waves in various gas discharges are presented. (M.O.W.)

59099 NONLINEAR INTERACTION OF ELECTRON PLASMA WAVES. Franklin, R. N. (Oxford Univ.). pp 574-85 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

The following topics are discussed in general terms: (1) large-amplitude waves, (2) resonant interactions, (3) parametric generation, (4) nonlinear Landau damping and (5) plasma wave echoes. (M.O.W.)

59100 GUIDED ELECTRON PLASMA WAVES. Anicin, B. A. (Boris Kidric Inst. of Nuclear Sciences, Belgrade). pp 586-613 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

A review is given of research carried out at the Boris Kidric Institute of Nuclear Sciences in Belgrade on slow electromagnetic waves on plasma columns. The following areas are described: (1) dispersion relations of surface waves on inhomogeneous plasma, (2) measurements of attenuation, (3) effects of phase modulation on attenuation measurements, (4) radiation fields associated with surface waves, and (5) pulse propagation on positive columns in the form of surface waves. (M.O.W.)

59101 NEW TECHNIQUE FOR THE OPTICAL GENERATION OF ELECTRON PLASMA WAVES. Burgess, D. D.; Richards, A. G.; Mahon, R. (Imperial Coll. of Science and Tech., London). J. Phys., B (London); 4: No. 9, L76-80(Sep 1971).

The coupling between transverse and longitudinal fields caused by bound electrons in a plasma provides a practical means for the optical generation of electron plasma waves (plasmons). The process has a threshold above which it becomes self-stimulated. (auth) (UK)

59102 TRANSVERSE WAVES AND INSTABILITIES IN A UNIFORM PLASMA FOR PROPAGATION ALONG THE MAGNETIC FIELD. Sestero, A.; Curatolo, M. (Laboratori Gas Ionizzati, Frascati, Italy). Nuovo Cim.; 5B: No. 2, 165-80 (11 Oct 1971).

A compact survey is presented of the linear theory of transverse waves and instabilities in a uniform plasma, for propagation along the magnetic field. Both the multifluid and the kinetic description are considered, the latter according to Landau's approach. The stability properties of the equilibrium are discussed in terms of marginal mode analysis (rather than in terms of Nyquist diagrams), leading to certain stability criteria. Damping and growth rates are explicitly evaluated in the long-wavelength limit for a number of waves and instabilities (e.g., the electron whistler mode, the electromagnetic modes, the transverse temperature anisotropy, and loss-cone instabilities). (auth)

59103 DAMPING OF DRIFT WAVES. Mazimov, R. K. Zh. Prikl. Mekh. Tekh. Fiz.; No. 1, 53-5(Jan-Feb 1970). (In Russian).

The absorption of monochromatic waves propagating in inhomogeneous plasma at angles to the magnetic field is studied. Nonlinear equations of resonance particles are resolved in the drift approximation. The nonlinear decrement of damping is calculated. (tr-auth)

59104 INFLUENCE OF LONGITUDINAL DENSITY GRADIENT ON THE TRANSFORMATION AND EMISSION OF TRANSVERSE WAVES FROM A BEAM-PLASMA DISCHARGE. Berezin, A. K.; Berezina, G. P.; Erokhin, N. S.; Moiseev, S. S.; Fainberg, Ya. B. JETP Lett. (USSR) (Engl. Transl.); 14: No. 3, 97-9(5 Aug 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 3, 149-52(5 Aug 1971).

An experimental and theoretical investigation was made of the efficiency of the processes of transformation of longitudinal waves into transverse ones as a function of the direction of the longitudinal density gradient. It is shown that the sign of the density gradient strongly influences the radiation intensity of the transverse waves. (M.O.W.)

59105 COUPLED EQUATIONS IN THE THEORY OF LINEAR WAVE CONVERSION. Fidone, I. (CEN, Fontenay-aux-Roses, France). Nuovo Cim.; 5B: No. 2, 219-36(11 Oct 1971).

The problem of linear conversion of electromagnetic waves into short-wavelength plasma modes is formulated in the framework of the theory of coupled equations for characteristic waves. The method of Clemmow and Heading is generalized to warm plasma, obtaining second-order coupled equations with the coupling reduced as far as possible. The equations have a relatively simple form for three cases, namely: (i) $k_x = 0$ and l, m, n arbitrary, (ii) $k_x \neq 0$, $m = n = 0$ and $l = 1$, and (iii) $k_x \neq 0$, $m = l = 0$ and $n = 1$. Here l, m, n are the direction cosines of the external magnetic field, k_x is the constant component of the wave vector and the plasma is weakly inhomogeneous along the z direction. The equations show that near the region where wave conversion takes place only one of the two characteristic waves of the cold plasma is of interest. A detailed analysis of the Foersterling coupling parameter for case (ii) is carried out, and the conditions for further simplifications are found. (auth)

Shielding

59106 BREMSSTRAHLUNG YIELD AS FUNCTION OF TARGET THICKNESS AND ATOMIC NUMBER IN THE ELECTRON ENERGY RANGE 12 TO 22 MeV. Kovalev, V. P.; Kharin, V. P.; Gordeev, V. V.; Borisov, M. S. At. Energ. (USSR); 31: No. 3, 289-92(Sep 1971). (In Russian).

Using a direct electron beam from a linear accelerator, the yield of bremsstrahlung was determined as a function of target thickness for Al, Ti, Cu, Mo, Ta, and W discs 40 mm in diameter. The detector was placed 1 m from the target and on the beam axis; it consisted of a thimble detector with an adapter and threshold indicators [$^{63}Cu(\gamma,n)^{62}Cu$, etc.] for sensing bremsstrahlung. Relative yields from different targets were measured with various detectors for electron-beam energies of 12.5, 16, and 22 MeV. The data are given in the form of tables and graphs. (K.S.W.)

59107 MEASUREMENT OF PHOTON INDUCED HIGH ENERGY SECONDARY ELECTRON EMISSION. Spencer, Russell Boone. Los Angeles; Univ. of California (1970). 246p. University Microfilms Order No. 71-16,365.

Thesis.

Experiments were performed to measure the energy and angular distributions of secondary electrons emanating from several target materials. Eight materials (Al, Ti, Cu, Mo, Cd, Ta, Pb and U) ranging in thickness from 0.003″ to 0.5″ were used. The photon source used for the experiment was a 3-Ci ^{60}Co source with photopeaks at 1.17 and 1.33 MeV. Pulse-height spectra (256 energy groups) of the emitted electrons were measured at 0, 10, 15, 20, 25, 30, 40, 50, and 60° to the beam forward direction for the gamma beam normal to the target. The pertinent theoretical aspects of electron generation by photons and electron emission from material are presented. Based on a general theoretical model of secondary electron generation in matter and emission from materials, two simplified models are investigated for their utility in predicting high-energy secondary electron emission. The results of numerical calculations based on the two models are compared with the results of the experiment. In addition, the results of a survey of previous experimental research concerning photon-induced secondary electron emission are summarized and compared with the results of the UCLA—NEL experiment. A computer program was developed to analyze and reduce the data collected by the pulse height analyzer. The program computes the differential and integral electron energy and angular distributions from the raw experimental data and plots them. The reduced experimental results are compared with: (1) numerical results calculated by employing a simplified secondary electron emission model, (2) numerical results obtained by using Monte Carlo techniques for predicting the photon and electron transport, and (3) experimental results obtained from other researchers. (TSS) (Diss. Abstr. Int., B)

59108 SEMIEMPIRICAL FORMULAS FOR GAMMA-RAY DOSE RATES THROUGH TWO-LAYER SLAB SHIELDS. Sharp, David A.; Carnesale, A. (North Carolina State Univ., Raleigh). Nucl. Technol.; 12: No. 4, 375-80(Dec 1971).

A series of dose-rate calculations in two-layered slab shields was performed, using a Monte Carlo technique, at combinations of source energy and slab thickness selected with the aid of a composite experiment design. Least-squares fits to the dose-buildup factors obtained from these calculations yield equations in which the dose buildup factor is represented as a quadratic function of the source energy and the thicknesses of the materials composing the shield. The accuracy of these equations was established by comparisons with existing data. (auth)

59109 TRANSPORT THEORY. Proceedings of the Symposium on Interdisciplinary Applications of Transport Theory, Oxford, England, September 1–4, 1970. Atlas Symposium No. 3. J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 511-1030 (Jun 1971). (CONF-700970).

Thirty-eight papers were presented at the Symposium. Separate abstracts were prepared for eighteen considered to be within the scope of NSA. (UK)

For abstracts of individual papers see: 58467—58474, 58543, 59041, 59110—59114, and 59682—59684.

59110 BELLMAN'S NEW APPROACH TO THE NUMERICAL SOLUTION OF FREDHOLM INTEGRAL EQUATIONS WITH POSITIVE KERNELS. Gruschinske, Juergen; Ueno, Sueo (Kyoto Univ.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 641-6(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

Using Bellman's new technique, it is shown how to solve numerically the integral equation of the source function of the radiation field in a homogeneous, isotropically scattering spherical medium or hollow spherical shell medium with no flux of radiation incident on the outer surface and with an isotropically emitting central point source. By Bellman's method, the integral equation for the source function is converted into a system of linear simultaneous, first order ordinary differential equations of the initial value type. (auth) (UK)

59111 MULTIGROUP TRANSPORT EQUATION WITH A SEPARABLE KERNEL. Silvennoinen, P.; Zweifel, P. F. (Virginia Polytechnic Inst., Blacksburg). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 869-77(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

An N-group, one-dimensional, time-independent transport equation with a separable scattering kernel is considered. Full- and partial-range completeness relations are proved, using the methods described in the book of Vekua. The procedures used are simple generalizations of a similar problem with two energy groups treated by the same authors elsewhere. (auth) (UK)

59112 MILNE'S PROBLEM FOR TWO-DIMENSIONAL TRANSPORT IN A QUARTER SPACE. Lam, S. K.; Leonard, A. (Stanford Univ., Calif.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 893-904(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

Double Fourier transformation of the one-speed transport equation is used to determine a family of solutions to the homogeneous (Milne's) problem for the quarter space. All contributions to the density asymptotically away from the corner are determined explicitly by considering two appropriate half-space problems and by extensive use of contour integration in two complex variables. An iterative scheme previously derived may be used to determine the correction near the corner. (auth) (UK)

59113 PROPERTIES OF NEW NUMERICAL APPROXIMATIONS TO THE TRANSPORT EQUATION. Lathrop, K. D.; Carlson, B. G. (Los Alamos Scientific Lab., N. Mex.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 921-48 (Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

Two new numerical methods are formulated for the solution of the Boltzmann transport equation. Both methods are designed to reduce distortion of angular flux distributions produced by conventional S_N or discrete-ordinates formulations. For the first method, in which the distribution function is represented by a set of discrete discontinuous straight lines, a general formulation is given; and, as an example, finite-difference equations are derived for two-dimensional rectangular geometry. The relationship to connected straight line and step function representations is shown, and an estimate of the relative truncation error of these schemes is given, showing that the new scheme has the potential of suppressing spatial oscillations without loss of second-order accuracy. By Fourier analysis of the line-source problem, it is shown that the lowest order of the new approximation (CS_2) compares favorably with the usual S_4 discrete-ordinates approximation in the suppression of ray effects. This result is confirmed by numerical comparisons. The second new method involves the conversion of two (or higher) dimensional discrete-ordinates equations to angular moments equations to eliminate the directional streaming properties of discrete-ordinates equations. Three approaches are examined for these conversions. In the first, the general formula is given for the artificial source needed to truncate the spherical harmonics moments equations derived from discrete-ordinates equations in (x,y) rectangular geometry. While it is shown that the moments in these equations may not be the coefficients in the polynomial expansion of the discrete-ordinates flux, numerical results from this conversion show greatly smoothed scalar fluxes. A second conversion formula, in which an artificial source is introduced to make the highest-order spherical-harmonics moments vanish, also produces smooth fluxes in numerical examples but requires more iteration than the first method. In the third approach, artificial source corrections to convert discrete-ordinates equations to angular-moments equations with exact equivalence are given. (auth) (UK)

59114 NUMERICAL SOLUTION OF THE UNSTEADY RADIATIVE-TRANSFER EQUATION. Hankin, B. C.; Hill, J. G.; Warham, A. G. P. (Atomic Weapons Research Establishment, Aldermaston, Eng.). J. Quant. Spectrosc. Radiative Transfer; 11: No. 6, 949-62(Jun 1971).

From Symposium on the application of transport theory; Oxford, England (1 Sep 1970).

XUM

In problems involving the transport of radiation through matter, it is necessary to solve the radiative transfer equation numerically. The scope for analytic solutions is restricted because of the complexity of the radiation–material interaction problem; this is particularly severe if the material is compressible. A study is made of various difference schemes within the framework of the discrete S_N method with a view to obtaining a well-behaved solution. In addition to the usual requirements of consistency, stability, and accuracy, there are further desirable features. Firstly, it is preferable to keep in the difference scheme, the photon conservation property as expressed by the basic transport equation. Secondly, the solution should be non-negative, not only because such values are unphysical, but also because of their effect on the radiation–material coupling. Such a coupling is usually nonlinear, and negative solutions can lead to instabilities in the numerical solution. Finally, it is preferable that the method should lead to simple calculations. Results are given for an example involving the radiative heating of a semi-infinite slab. It is shown that the diffusion limit imposes a particularly severe test, and the method used by Lathrop in the computer code DTF-IV is favored. A second example demonstrates a disturbing oscillatory behavior arising from Diamond differencing which is basic to the DTF-IV method. A modification to this method designed to overcome this problem is examined. (auth) (UK)

59115 EFFECT OF SECONDARY EMISSION ON THE POTENTIAL OF A METALLIC BODY IN ELECTRONIC RADIATION FIELDS ON THE EARTH. Ryabova, T. Ya.; Trukhanov, K. A. Izv. Akad. Nauk SSSR, Ser. Fiz.; 35: No. 5, 1075-9(May 1971). (In Russian).

Much experimental and calculated data is available on the equilibrium potential relative to unscreened cosmic instrumentation in magnetospheric plasma. Screening the equipment with thin outer screens (~0.01 g/cm^2) leads to a change of conditions of the formation of the equilibrium potential because of the redistribution role of leakage currents in the total balance of charge. The possibility of establishing a large negative charge on the screened cosmic apparatus was examined, which might be used for radiation protection of the system, materials, and crew from intense electron currents. Screening leads to absorption of uv radiation of the sun and of ions of the magnetospheric plasma, causing a charge loss from the surface of unscreened apparatus. A theoretical analysis of these conditions is presented, in which a metallic body represents the apparatus in question. The final equation permits calculation of the integral dose of bremsstrahlung from electrons permissible in a flight. (K.S.W.)

59116 COMPARISON OF RANGE-ENERGY CALCULATIONS OF HEAVY IONS IN SILICON USING THE INVERSE SQUARE LAW AND THOMAS–FERMI POTENTIALS. Littlejohn, M. A.; Holloman, S. B. (North Carolina State Univ., Raleigh). Radiat. Eff.; 10: No. 1-2, 133-4(Jul 1971).

The projected range and projected range straggling of heavy ions in silicon are calculated using an inverse square law potential. These results are compared with similar computations using the Thomas–Fermi potential. It is shown that there is reasonable agreement between these two models for ion energies between 20 and 400 keV. (auth)

59117 SEMI-EMPIRICAL REPRESENTATIONS OF NEUTRON AND GAMMA RAY DOSE RATES IN TWO-LAYERED SLAB SHIELDS. Sharp, David Alexander. Raleigh, N. C.; North Carolina State Univ. (1970). 152p. University Microfilms Order No. 71-20,147.
Thesis.

Equations are developed that specify the dose rate due to the attenuation of neutrons and gamma rays through shields composed of two materials. These equations are generated from least-squares fits to dose rate data that are calculated using a Monte Carlo computer code. The calculations are performed at a series of independent-variable combinations that are selected using a composite experiment design. For gamma rays, the dose buildup factor of the radiation emerging from the shield is expressed as a quadratic function of the energy of the incident radiation and the optical thickness of the shield materials at this energy. The equations are developed for shield material combinations of lead/water, water/lead, iron/water, and water/iron. They are applicable for incident energies from 0.5 to 10 MeV and for individual slab thicknesses from 0.5 to 5.0 mean free paths. The dose rates yielded by these equations are compared extensively with data from the literature. The mean difference that results from these comparisons is within 10% for each equation. The total dose rate resulting from the attenuation of uranium-235 fission neutrons in a composite shield of iron and water is expressed as a quadratic function of the thicknesses of these materials. Collided dose rates are computed using the Monte Carlo code, while uncollided dose rates are determined from a numerical integration procedure. The resulting equation is applicable for iron thicknesses up to 4 inches, followed by up to 12 inches of water. The total dose, as predicted by this equation, decreases approximately exponentially with increasing shield thickness. A calculation of the penetration of secondary gamma radiation produced by neutron inelastic scattering, performed at one thickness combination, indicates that the dose resulting from this effect amounts to less than 1% of the total. (Diss. Abstr. Int., B)

59118 COMPTON AND RAYLEIGH SCATTERING OF X RAYS BY HETEROGENEOUS MATERIALS. Bramwell, S. E.; Carr-Brion, K. G.; Stuart, J. P. (Warren Spring Lab., Stevenage, Eng.). Nature (London) Phys. Sci.; 233: No. 36, 8-9(6 Sep 1971).

During studies of Compton and Rayleigh scattering from suspensions and slurries it was observed that the x-ray intensities showed a marked dependence on the size of the grains of the more strongly absorbing component, and a detailed study of these effects is described, in view of the potential industrial application of the technique to the determination of particle size. Uranium L x rays, obtained from a sealed 30-mCi ^{238}Pu source, were employed for the studies. (UK)

59119 γ-RAY INDUCED SCINTILLATION. Zhemerev, A. V.; Medvedev, Yu. A. This paper was summarized in At. Energ. (USSR); 29: No. 4, 287(Oct 1970) as paper No. 435/5837. (In Russian).

The characteristics of scintillation in air induced by a nonstationary, isotropic, point γ radiator is investigated taking into account effects of time retardation and self-absorption of light in the volume of the radiator due to the knocking-off of electrons from negative ions of oxygen. (M.H.R.)

59120 INVESTIGATION OF BUILDUP REGION FOR γ-RADIATION FROM LOW-LEVEL SOURCES. Stavitskii, R. V.; Yarkovoi, E. A.; Kheteev, M. V. This paper was summarized in At. Energ. (USSR); 29: No. 5, 366(Nov 1970) as paper No. 442/5725. (In Russian).

Experimental investigation of buildup curves revealed the absence of buildup regions when radiation from low-level sources (specific activity from 4.5 to 450 μCi/g) is recorded. The apparent reason is contamination of the primary beam by electrons or photons of energy below 400 keV. It was found that contamination of the primary beam by photons of energy below 400 keV takes place through scattering of the primary radiation within the source itself. Experimental investigations relying on photographic and scintillation techniques were carried out in order to arrive at a tentative estimate of the amount of radiation scattered by a γ source. The photographic method was applied to a study of the effect of radiation scattered by thin (2-mm-thick) aluminum, iron, and lead radiators. Because of the radiation scattered by the source and by the radiator, the film ended up more fogged than anticipated. The amount of γ radiation scattered by the source itself was estimated by analyzing the change in the spectrum of the collimated radiation measured by a scintillation detector placed after filtration of the radiation by a thin filter. A special procedure developed for processing the spectrograms made it possible to obtain the relative spectral distributions of the scattered radiation in the sources. (auth)

59121 FOURIER TRANSFORM METHODS IN LINEAR TRANSPORT THEORY. Case, K. M. (Rockefeller Univ., New York); Hazeltine, R. D. J. Math. Phys. (N. Y.); 12: No. 9, 1970-80 (Sep 1971).

A three-dimensional Fourier transform method presented previously is generalized to solve various forms of the linearized transport equation in planar geometry. Infinite-space problems are in general easily treated by the procedures. Half-space problems may also be solved analytically in, at least, the following cases: (i) separable scattering kernel (arbitrary particle speed); (ii) one-speed, anistropic scattering with rotation-invariant kernel; (iii) one-dimensional energy-dependent kernel of Kac; (iv) multigroup transport with down scattering only. The general importance of recursion relations to problems with nonseparable kernels is emphasized. A comparison is made between these methods and the two-dimensional singular eigenfunction approach, and a criterion is presented for the analytic solubility of any problem of the general form considered. (auth)

59122 PRECISE MEASUREMENTS OF W, THE MEAN ENERGY EXPENDED PER ION PAIR FORMED IN ALKANE VAPORS AND IN ARGON. Stoneham, Thomas Ash. Houston, Tex.; Univ. of Houston (1970). 97p. University Microfilms Order No. 71-19,102.
Thesis.

Ionization currents were measured for the complete stopping of ^{63}Ni beta rays in nitrogen, in argon, in the normal alkanes through heptane and in the branched-chain alkanes through hexane. Values of W, the mean energy expended per ion pair formed, were determined from the ratio of ion current in nitrogen to that in the sample, relative to the W for nitrogen, 34.6 eV [G. N. Whyte, Radiation Res., 18: 265(1963)]. W(beta) values for alkanes were measured with a precision of ca 0.1% and that of argon within 0.2%. No variation of W was experienced as pressures were increased by a factor of two, up to 2700 torr. There is also no temperature dependency in argon, methane, ethane, and propane in the 25° to 200°C range. Energy-balance considerations reveal that at least half of the energy absorbed in the complete stopping of electrons in vapors of normal alkanes C_1 to C_5 is expended in ionization, while about one third goes into excitation and the rest remains in subexcitation electrons. W(beta) correlates well with molecular structure in the normal and branched alkanes. Ionization potentials (I_0) as well as W's may be predicted empirically by extrapolating values from tables of W, I_0, and W/I_0. (Diss. Abstr. Int., B)

59123 IONIZATION MEASUREMENTS IN MERCURY VAPOR WITH BETA PARTICLES AND THE MEAN ENERGY TO FORM AN ION PAIR. **Jesse, William P. (St. Procopius Coll., Lisle, Ill.). J. Chem. Phys.; 55: No. 7, 3603-4(1 Oct 1971).**

Ionization currents formed in Hg vapor by bombardment by ^{63}Ni β particles were measured successively as the pressure of the gas was raised. The mean energy for formation of an ion pair, W, was calculated by comparing these results with corresponding measurements for argon for which the W value is precisely known. The value obtained for W_{Hg} was 23.6 ± 0.2 eV/ion pair. The ratio of W to the lowest ionization potential of the gas was found to be 2.27. (A.G.W.)

59124 INELASTIC ENERGY LOSSES OF SLOW IONS IN SOLIDS. Yarkulov, U. (Inst. of Nuclear Physics, Tashkent). Izv. Akad. Nauk Uzb. SSR, Ser. Fiz.-Mat. Nauk; No. 2, 69-72 (1970). (In Russian).

A screened Coulomb potential was used in deriving formulas for energy losses of slow ions in solids. The velocity of the electrons of the slowing-down medium was taken into account. The formulas were used to calculate the electronic stopping powers of Au, Ag, Al, and Li for protons at energies of 20 to 1000 keV. It is concluded that energy losses of protons depend nonmonotonically on the atomic number of the stopping material and are related to atomic shell structure. (A.G.W.)

59125 (JUL-729-FF) DETERMINATION OF THE ANISOTROPY OF THE THRESHOLD ENERGY FOR THE PRODUCTION OF FRENKEL DEFECTS IN TANTALUM. **Jung, Peter (Kernforschungsanlage, Juelich (West Germany). Institut Festkoerperforschung). Feb 1971. 71p. (In German). Dep. NTIS (U. S. Sales Only).**

Thesis. Submitted to Technische Hochschule, Aachen, Ger.

The effective cross section for the production of Frenkel pairs was determined on 15-μ Ta crystal foils with (110) orientation. The cross section was determined in the energy range from 1.0 to 3.2 MeV in dependence on the orientation of the foil to the electron beam over a wide range in the orientation triangle. In contrast to the previously studied fcc metals Cu and Au, a strong directional dependence of the damage rate was found in the energy range over 1.3 MeV. The measurement values were corrected with reference to the beam propagation through the finite sample. An attempt was made to adapt various threshold-energy profiles to these corrected values. A satisfactory agreement was obtained only with those profiles in which the mean threshold energy in the regions of 20° around the (111) direction increases 36 ± 2 eV, in the regions of 18° around the (100) direction 53 ± 3 eV, and in the region between the principal direction to over 130 eV. The existence of such windows about the principal directions strongly indicate that stable Frenkel pairs were produced by displacement collisions; i.e., in general, the primary bombarded atom does not form the interstitial atom. Whereas the occurrence of these threshold-energy windows around the (111) and (100) direction agrees with the results from the Erginsoy computer experiments for bcc iron, the relative sizes of the thresholds in the principal directions are in opposition to the results of Erginsoy and to the estimation of H. H. Andersen et al. for Ta. A value of 32 ± 2 eV was obtained as the lowest threshold and the resistance increase per at. % Frenkel pairs was 17 ± 3 μΩcm. (tr-auth)

59126 EFFECTS OF POINT DEFECTS ON ELASTIC PRECURSOR DECAY IN LITHIUM FLUORIDE. **Asay, James Russell. Pullman, Wash.; Washington State Univ. (1971). 184p. University Microfilms Order No. 71-18,559.**

Thesis.

Data are reported for shock wave propagation along a ⟨100⟩ crystallographic direction in single-crystal LiF. Shock waves were obtained by impacting the specimens with an aluminum (6061-T6) projectile at a velocity of approximately 0.34 mm/μsec. The average initial stress produced at the impact surface was about 28.6 kbars. Quartz gauges were used to measure attenuation of the elastic precursor for propagation distances ranging from about 0.25 mm to 15.5 mm. The maximum precursor amplitude observed in the study was approximately 21 kbars for a specimen 1 mm in thickness. A minimum value of about 2 kbars was observed for large propagation distances. The present study shows that elastic precursor decay in LiF is critically dependent upon the presence of point defects. These were in the form of cation impurities in most of the specimens and were obtained through gamma radiation in others. For the observed range in concentration, yield stresses measured at low strain rates varied monotonically with defect concentration from about 0.02 kbar for pure crystals to 1 kbar for the hardest material studied. Dynamic behavior was also strongly dependent on defect concentration. It was found that the corresponding precursor curves showed an initial rapid decay to an apparent equilibrium value of about 2 kbars for very soft crystals. The initial decay rate for hard crystals was also rapid, although the equilibrium stress was higher. However, a minimum in the decay rate was observed for materials which had an intermediate concentration of point defects. Dynamic data are compared with those obtained at low strain rate to show that dislocation processes are different for the two ranges of strain rate employed. Present data suggest that dislocation multiplication controls precursor decay in LiF. The study shows that multiplication behind the wavefront can account for at least half of the observed attenuation in materials which relax slowly. For materials which show a rapid decay, this effect is estimated to be approximately 10 to 30% of the total decay rate. A calculation is also presented which shows that multiplication in the wavefront can contribute significantly to the decay. (Diss. Abstr. Int., B)

59127 COMPARATIVE CHARACTERISTICS OF SUBTHRESHOLD RADIATION EFFECTS IN n- AND p-TYPE SILICON. **Zaikovskaya, M. A. (Inst. of Nuclear Physics, Tashkent). Izv. Akad. Nauk Uzb. SSR, Ser. Fiz.-Mat. Nauk; No. 2, 70(1971). (In Russian).**

The magnitude of the radiation-induced change in the specific resistance in n- and p-type silicon was measured as a function of the integrated flux of electrons of energies of from 10 to 100 keV. In samples of the n-type, the "sub-threshold" radiation effect was inversely proportional to the free electron concentration. In the p-type, it was directly proportional to the concentration of free holes. (K.S.W.)

59128 EFFECTS OF HEAT TREATMENT AND γ IRRADIATION ON THE PHOTODEFORMATION EFFECT IN GERMANIUM. Khiznichenko, L. P.; Yusupova, D. Yu. (Inst. of Nuclear Physics, Tashkent). Izv. Akad. Nauk Uzb. SSR, Ser. Fiz.-Mat. Nauk; No. 2, 74-5(1971). (In Russian).

Changes in the photodeformation effect was studied in germanium that had been given thermal and radiation treatments. Two types of monocrystals were used: n-Ge with a specific resistance of 26 ohm · cm and a density of dislocations of 10^4/cm, and a dislocation-free p-type of material with $\rho = 10$ ohm · cm. The radiation source was ^{60}Co yielding 150 R/sec; the thermal treatment consisted of maintenance at 500°C in a nitrogen atmosphere for 20 min, followed by chilling in liquid nitrogen. Chilling the samples produced a change in the photodeformation effect only in the dislocated samples. The photodeformation effect was suppressed in both types of Ge samples by exposure to γ radiation. (K.S.W.)

59129 ABNORMAL STOPPING POWER OF PROTON AND ION CHANNELING. **Ohtsuki, Yoshi-Hiko; Mizuno, Mitsuhiko; Kitagawa, Mitsuo (Waseda Univ., Tokyo). J. Phys. Soc. Jap.; 31: No. 4, 1109-12(Oct 1971).**

A method to calculate the abnormal stopping power of the planar channeled particle in crystal is proposed. Making use of the formula and Bohr's classical model, the abnormal stopping power is calculated as a function of the distance from the channeling wall for electronic and nuclear excitations. (auth)

59130 PROTON DECHANNELING IN Ge PROBES: THE CRYSTAL SCATTERING. **Campisano, S. U.; Grasso, F.;**

XUM

Rimini, E. (Istituto Nazionale di Fisica Nucleare, Catania, Italy. Univ., Catania, Italy). Radiat. Eff.; 9: No. 3-4, 153-64(Jun 1971).

Experimental data on proton dechanneling in Ge are reported; the general features of these results are similar to those reported for Si, although some quantitative differences appear according to the crystal nature. The available experimental data enable a detailed discussion of the approximations involved in dechanneling theory and in calculations. Some emphasis is given to the influence of the potential used to describe the ion–target interaction; significant differences appear on going from the Thomas–Fermi (Moliere) to Lindhard's standard potential. Remarks are also made on the description of the moving-ion interaction with the core and valence electrons as it concerns multiple scattering. The importance of the ion-beam diffusion because of multiple electronic and nuclear scatterings, so far neglected, was evaluated to be, except at large values of the dechanneled fraction, a small correction to the steady-increase description. (auth)

59131 THEORY OF DEFECTS IN IRRADIATED SEMICONDUCTORS. Stoneham, A. M. (Atomic Energy Research Establishment, Harwell, Eng.). Radiat. Eff.; 9: No. 3-4, 165-71(Jun 1971). (CONF-700824-39).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

Developments in the theory of defects in semiconductors are reviewed, with emphasis on changes since the Santa Fe meeting and on the points that were controversial then. It has become clear that most of the desirable simplifications are invalid for vacancies in diamond and silicon, and probably also for similar systems. In particular, one cannot use the one-electron approximation, the rigid-lattice approximation, or the Jahn–Teller instability with coupling within isolated levels alone, nor some of the conceptually acceptable treatments of the lattice distortion. The successes and weaknesses of the various approaches are reviewed, and some of the potential methods are described. (58 references) (auth)

59132 LOW-TEMPERATURE ANNEALING OF ELECTRON-IRRADIATED GERMANIUM. Hyatt, W. D.; Koehler, J. S. (Univ. of Illinois, Urbana). Radiat. Eff.; 9: No. 3-4, 177-9(Jun 1971). (CONF-700824-40).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

N-type germanium (4×10^{14} Sb/cm^3) was irradiated with 1.1-MeV electrons at 5°K. The defects produced were studied by measuring the voltage-dependent capacitance of a metal/germanium junction at the surface of a germanium sample. These measurements were made at 10°K and directly gave the fixed charge density near the surface of the sample. The production and recovery of defects seen near the surface is the same as seen in bulk experiments. A 0.5-MeV electron beam was used to cause radiation annealing of the defects at 5°K. The fraction recovered during radiation annealing is directly proportional to $\sqrt{t}$. A model based on diffusion-limited recovery theory is used to explain these results. This model is also used to discuss the results of previous experiments. The temperature dependence of the observed recovery at 5°K gave a defect migration energy of 0.0044 ± 0.0008 eV. (auth)

59133 DONOR–VACANCY TYPE COMPLEXES IN GERMANIUM. Emtzev, V. V.; Mashovets, T. V.; Maximov, M.; Vitovskii, N. A. (Ioffe Inst. of Physics and Tech., Leningrad). Radiat. Eff.; 9: No. 3-4, 181-7(Jun 1971). (CONF-700824-41).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

Very unusual energy spectra and defect production kinetics were observed under ^{60}Co γ irradiation and heat treatment of high-purity germanium. The results can be explained in terms of vacancy–donor and divacancy–donor complexes. The upper limit of the vacancy migration energy in germanium is estimated as 0.3 eV. (auth)

59134 PHONON SCATTERING AND INDUCED ENERGY LEVELS IN ELECTRON-IRRADIATED Sb-DOPED Ge IN THE n TO p-TYPE CONVERSION REGION. Laurence, G.; Albany, H. J. (CEN de Saclay, Gif-sur-Yvette, France). Radiat. Eff.; 9: No. 3-4, 189-94(Jun 1971). (CONF-700824-42).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

Low-temperature thermal conductivity results on Sb-doped Ge irradiated at ~40°C by 4-MeV electrons are reported. The change in K upon electron dose Φ was investigated in the n to p-type conversion region for two Sb concentrations, 8.4×10^{15} and 4.5×10^{17} cm^{-3}. The thermal conductivity behavior was shown to arise from electron–phonon scattering in relation to antimony levels, irradiation-induced energy levels, and their charge states. The different stages of K variation emphasize the dominant effects of the induced levels determined from Hall-effect measurements. The existence of a residual scattering near the n–p transition appears to be a striking feature that might indicate a particular role or structure for the acceptor centers in this region. (auth)

59135 DEFECTS IN SILICON: CONCEPTS AND CORRELATIONS. Stein, H. J. (Sandia Labs., Albuquerque, N. Mex.). Radiat. Eff.; 9: No. 3-4, 195-210(Jun 1971). (CONF-700824-43).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

A review of irradiation-produced defects in Si is presented, with emphasis on correlations of macroscopic properties with microscopic defects. Such correlations have been successfully used to interpret the electrical properties of irradiated n-type Si. Additional correlation studies are needed to obtain a more complete interpretation of the electrical properties of irradiated p-type Si. As a further step in this direction, new data are presented on the annealing recovery of the hole concentration in electron-irradiated Al-doped and B-doped Si. The concept of vacancy-rich defect clusters, together with concepts and data on point defects, explain many aspects of neutron radiation damage. The same defects, concepts, and correlations used in studies of electron- and neutron-produced damage are also useful for interpreting radiation damage produced by ion implantation. (94 references) (auth)

59136 STUDY OF ATOMIC DISPLACEMENTS IN He$^+$-IRRADIATED SILICON AND A SILICON–GERMANIUM ALLOY THROUGH RUTHERFORD SCATTERING. Baruch, P. (Ecole Normale Superieure, Tours, France); Abel, F.; Cohen, C.; (and others). Radiat. Eff.; 9: No. 3-4, 211-17(Jun 1971). (CONF-700824-44).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

The disorder created by He$^+$ ions of 275 keV and 1610 keV in Si and in a Si–Ge alloy (0.6 at. % Ge) was studied at 295 and 85°K through the use of channeling and backscattering of these ions. The disorder is measured through the relative yield of backscatter for the beam incident in $\langle 111 \rangle$ and $\langle 110 \rangle$ directions. In both crystals, the disorder is not linear with fluence, and shows a tendency to saturate. In many cases the disorder measured along $\langle 110 \rangle$ channels is larger than along $\langle 111 \rangle$ channels, which indicates a prevalence of interstitial-type defects. However, there is no indication of the structure of the defects. Part of the disorder could be attributed to slight displacements of atoms in the strain field of radiation defects. The low-temperature irradiations create more disorder than room-temperature irradiations, and this excess disorder does not fully anneal at 120°C. In Si(Ge), the number of Si or Ge scatterers is close to the concentration ratio even at high fluences. This shows there is no preferential process by which Ge interacts with Si defects. (auth)

59137 RADIATION-INDUCED DEFECTS IN DIAMOND. Clark, C. D.; Mitchell, E. W. J. (Univ. of Reading, Eng.). Radiat. Eff.; 9: No. 3-4, 219-34(Jun 1971). (CONF-700824-45).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

A critical review of radiation damage in diamond is presented, focusing on important specific centers rather than attempting a review of the whole field. The proposed models for these centers are examined and often found wanting. Phenomena observed in ion bombardment of diamond is discussed and found to probably be due to amorphous or graphite surface layers. Throughout the review, a number of suggestions of important experiments are given. (75 references) (auth)

59138 III–V COMPOUND REVIEW. Eisen, F. H. (North American Rockwell Science Center, Thousand Oaks, Calif.). Radiat. Eff.; 9: No. 3-4, 235-42(Jun 1971). (CONF-700824-46).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

Radiation effects in InSb, GaSb, and GaAs are reviewed with emphasis on damage production and comparison of recovery results. The orientation dependence of damage production at electron energies near threshold, the rather low values of the threshold displacement energy, and subthreshold damage effects are discussed. Consideration is given to a number of similarities in the recovery data for InSb and GaSb, and some differences between these materials and GaAs are discussed. (27 references) (auth)

59139 LUMINESCENCE OF IRRADIATED β–SiC. Geiczy, I. I.; Nesterov, A. A.; Smirnov, L. S. (Inst. of Semiconductor

Physics, Novosibirsk, USSR). Radiat. Eff.; 9: No. 3-4, 243-6 (Jun 1971). (CONF-700824-47).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

The influence of electron irradiation with energy of 3.5 MeV on the luminescence of cubic silicon carbide (β-SiC) was investigated. It was shown that irradiation results in the diminution of edge emission and appearance of the red band (2.0 to 1.3 eV). The obtained results give an opportunity to consider the red band as transitions from exicted states. The data on temperature stability of irradiated damage is given. The probable nature of irradiated defects are discussed. (auth)

59140 DAMAGED REGIONS IN NEUTRON-IRRADIATED AND ION-BOMBARDED Ge AND Si. Swanson, M. L.; Parsons, J. R.; Hoelke, C. W. (Atomic Energy of Canada Ltd., Chalk River, Ont.). Radiat. Eff.; 9: No. 3-4, 249-56(Jun 1971). (CONF-700824-48).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

The formation of amorphous or crystalline damaged regions by ion bombardment or neutron irradiation of Ge and Si is discussed. Several experiments have demonstrated that Ge and Si become amorphous when bombarded to high fluences with ions of 20 to 200 keV energy, but remain crystalline after low ion fluences ($<10^{14}/cm^2$) or after fission neutron irradiations up to very high fluences. The present results indicate that a fission neutron fluence of 5×10^{20} n/cm^2 at ~50°C and at a flux of 6×10^{13} n/cm^2/sec produces no amorphism in Ge or Si, but that microcrystals appear after annealing at 450°C. It is concluded that the individual damaged regions produced by high-energy ions or by primary knock-on atoms from fission-neutron collisions are crystalline. When these damaged regions are created rapidly enough so that overlap occurs before appreciable annealing of point defects takes place, the damaged regions become amorphous. The critical defect concentration required for spontaneous transformation to amorphism is estimated to be 0.02. (auth)

59141 PREFERENTIAL ETCHING OF ION-BOMBARDED GaAs. Arnold, G. W.; Whan, R. E.; Maurin, J. K.; Borders, J. A. (Sandia Labs., Albuquerque, N. Mex.). Radiat. Eff.; 9: No. 3-4, 257-60(Jun 1971). (CONF-700824-49).

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

Abrupt changes in the near-band-edge luminescence of n-type undoped GaAs after implantation with 400-keV Zn ions and vacuum annealing at 580°C are reported. The good agreement of the spectral position, half-width, and temperature dependence of the emission obtained after implantation and annealing with that of melt-doped GaAs : Zn indicates that implanted Zn ions were incorporated at Ga lattice sites. The larger number of Zn substitutions obtained when bombardment is made on the Ga face than for an equivalent fluence on the As face demonstrates the existence of a polar implant effect. (auth)

59142 RECOVERY OF RHENIUM FOLLOWING LOW-TEMPERATURE ALPHA-PARTICLE IRRADIATION. von Heyden, G.; Vandenborre, H.; Stals, L.; Nihoul, J. (SCK/CEN, Mol, Belg.). Radiat. Eff.; 9: No. 3-4, 279-81(Jun 1971).

A resistometric study was made of the annealing recovery of pure polycrystalline Re following irradiation at 5°K by ^{242}Cm sources. The results are compared with these for thermal-neutron irradiation at 3.7°K (Coltman et al., Phys. Rev. 156: 715(1967)). The alpha-particle-induced resistivity was 20 to 30 nΩ cm, an order of magnitude larger than from thermal neutrons. The first resolvable recovery peak is I_3 at 32°K, and the I_6 stage is split up into three or four substages at 73 to 97°K. (D.L.C.)

59143 ALPHA- AND BETA-MAGNETIC EFFECTS IN HOMOGENEOUS GERMANIUM MONOCRYSTALS. Simonenko, D. L. At. Energ. (USSR); 31: No. 3, 237-8(Sep 1971). (In Russian).

A novel physical phenomenon is described that occurs when the surface of a homogeneous (junction-free) Ge crystal, resting in a permanent magnetic field, is irradiated with α or β particles. (The α and β sources used in the experiments were a ^{238}Pu preparation and a ^{90}Sr-^{90}Y preparation, respectively.) A difference of potential arises which is directed along the plate, i.e., perpendicular to the direction of the magnetic field and the direction of the beam of bombarding particles. (K.S.W.)

59144 COMPARISON OF DISPLACEMENT RATES PRODUCED BY ION BOMBARDMENT AND NEUTRON IRRADIATION. Doran, D. G. (WADCO Corp., Richland, Wash.); Kulcinski, G. L. Contracts AT(45-1)-2170; AT(45-1)-1830. Radiat. Eff.; 9: No. 3-4, 283-4(Jun 1971).

Refinements are made of estimates (Kulcinski et al., Radiat. Eff., 7: 195(1971)) of atom displacement rates for comparison of ion bombardment and neutron irradiation in stainless steel. The ratio of the energy lost by knock-on atoms in nuclear collisions to the energy lost in primary nuclear collisions was calculated for Cu ions with incident ion energies of 1 and 5 MeV and several energy transfer values. The approximate EBR-II neutron fluence (E > 0.1 MeV) required to produce the same number of displaced atoms as 2×10^{16} ions/cm^2 was calculated to be 3×10^{22} n/cm^2. (D.L.C.)

59145 ATOMIC INTERACTION POTENTIAL FOR NICKEL. Kaletta, D. (Kernforschungszentrum, Karlsruhe, Ger.). pp 319-22 of Voids Formed by Irradiation of Reactor Materials. /Pugh, S. F. (ed.). London; British Nuclear Energy Society (1971).

From Voids formed by irradiation of reactor materials conference; Reading, England (24 Mar 1971).

An inverse power interaction potential V_{inv} (r) = $(Z_1Z_2e^2/sr^s)$ a_{inv}^{s-1}; $1 \leq s < \alpha$ was used to determine the displacement cross section and the range of bombarding ions in a polycrystalline target. A random structure for the target was assumed and classical mechanics employed throughout. The construction of the interaction potential from low-energy values (≥25 eV) to high values (≤100 MeV) was achieved both from using the Born-Mayer potential of the target and by superposing the Born-Mayer and the Bohr potentials. The screening length a_{inv} and the exponent S were calculated using a semi-empirical procedure. An advantage of a simple potential with only two semi-empirically determined parameters is that errors are made minimal. (UK)

59146 ENERGY DEPENDENCE OF SECONDARY-ELECTRON EMISSION IN CRYSTALS. Zommerfel'dt, Kh.; Mashkova, E. S.; Molchanov, V. A. (Moscow State Univ.). Sov. Phys.-Solid State (Engl. Transl.); 13: No. 3, 676-9(Sep 1971).

Translated from Fiz. Tverd. Tela; 13: No. 3, 819-23(Mar 1971).

The energy dependence of the secondary electron emission coefficient of germanium crystals bombarded by ions of an inert gas is studied experimentally. The observed relations are discussed on the basis of ion channeling in crystals. The accepted model makes it possible to explain the smoothing of the angular dependence of the secondary electron emission coefficient at lower ion energies and to evaluate the contribution of channeled ions to emission. (auth)

59147 OSNOVY RADIATSIONNOGO MATERIALOVEDENIYA STEKLA I KERAMIKI. (Radiation Effects on Glass and Ceramics). Brekhovskikh, S. M.; Viktorova, Yu. N.; Grinshtein, Yu. L.; Landa, L. M. Moscow; Izdatel'stvo Literatury po Stroitel'stvu (1971). 256p.

The effects of types and doses of radiation on the various properties of glass and ceramics are presented. The optical absorption in glasses of simple composition and radiation-optical stability of industrial glasses are considered. Other chapters focus attention on the formation and destruction of color centers, luminescence, and resonance absorption in glasses. Radiation effects on the electrical properties of glass and ceramics and on the structure of materials (density, volume, and phase composition) are discussed. Absorbers of hard radiation and thermal neutrons are reviewed, accompanied by a summary of radiation-sensitivity of materials, particularly as applied to the construction of dosimeters and scintillators. (516 references) (K.S.W.)

59148 SPECIFIC HEAT OF NEUTRON IRRADIATED GRAPHITE BETWEEN 1.4 AND 4.4 °K IN THE PRESENCE OF A VARIABLE MAGNETIC FIELD (0 TO 40 kGs). Delhaes, Pierre; Lemerie, M. Y.; Blondet-Gonte, Gilbert (CNRS, Talence, France). Compt. Rend., Ser. B; 272: No. 23, 1285-8(7 Jun 1971). (In French).

The specific heat of heavily irradiated graphite was measured in the presence of a variable magnetic field; a magnetic component of the specific heat, linked with the existence of stable paramagnetic centers, is established. (France)

59149 BREMSSTRAHLUNG FROM 7- TO 10-MeV ELECTRONS IN THIN SILICON CRYSTALS. Komar, A. P.; Korobochko, Yu. S.; Mineev, V. I.; Petrochenko, A. F. (Leningrad Polytechnic Inst.). Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 631-6 (Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 807-14(Apr 1971).

An experimental study was made of bremsstrahlung spectra from single-crystal silicon targets 7 to 11 μ thick bombarded with 7 to 10 MeV electrons in the [110] direction. The heights of the coherent peaks relative to the incoherent part of the spectrum are in satisfactory agreement with the calculated values. (auth)

59150 DISTRIBUTION OF ENERGY LOSSES FOR HEAVY POSITIVE PARTICLES IN A SINGLE CRYSTAL. Kalashnikov, N. P.; Remizovich, V. S.; Ryazanov, M. I. (Moscow Engineering

XUM

Physics Inst.). JETP Lett. (USSR) (Engl. Transl.); 13: No. 12, 508-10(20 Jun 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 13: No. 12, 715-18(20 Jun 1971).

For the case of channeling of heavy particles in a single crystal, an approximation of the energy losses is derived in which the inelastic processes are described in a very simple manner. Channeled particles lose an energy smaller by a factor

$$\left(1 - \ln\frac{v}{e^2\sqrt{Z_1^{2/3} + Z_2^{2/3}}} \Big/ \ln\frac{2m_e v^2}{l_z}\right)$$

than the nonchanneled ones. The distribution function of the energy loss is in agreement with the experimental results of C. Erginsoy for protons in Si single crystals, with the loss of channeled particles being 0.45 of that of unchanneled ones (calculated factor = 0.5). (D.L.C.)

59151 APPLICATIONS OF THE CHANNELLING AND BLOCKING EFFECTS. **Czegledy, Sandor (Nuclear Research Inst., Debrecen, Hungary). Atomtech. Tajek.; 13: No. 8, 473-8(Dec 1970). (In Hungarian).**

The channeling effect is an old and forgotten phenomenon that has been recently rediscovered. It is based on channels lying in specific directions within the crystals, created by the low Miller index crystal planes. If a beam of charged particles is directed against the crystal in a direction parallel with the axis of the channel, the energy loss of the particles resulting from interaction with the atoms at the channel wall will be decreased. The blocking effect is the opposite phenomenon, involving blockage of the passage of particles in certain directions. These two effects influence the radiation damage of ion implantation occurring during ionic bombardment. The effect may be used to determine the lifetime of intermediate nuclei on the basis of its recoil velocity. The blocking effect may also be used to determine the relative vibration amplitude of lattice vibrations. Both effects promise to become an important tool for atomic and solid-state physics. (22 references). (TTT)

59152 F-AGGREGATE CENTERS IN SODIUM CHLORIDE. I. **Jun, Moo Jin; Neubert, Theodore J. (Illinois Inst. of Tech., Chicago). J. Chem. Phys.; 55: No. 4, 1583-7(15 Aug 1971).**

Thermal aggregation of electron-excess color centers in NaCl, x-irradiated at 80°K, was studied by observation of changes in optical absorption in pulse annealing experiments. An initial 80-hr x irradiation introduced large concentrations of F, F′, and positive hole centers. As annealing temperatures were raised (80 → 235°K), recombination of thermally released positive holes with electrons in F centers produced α centers. Thermal aggregation of F centers occurred above 240°K when α centers become mobile. M^+ centers (F_2^+) form and disappear and M centers (F_2) increase rapidly in number near 265°K as a result of the reactions $F + \alpha \rightarrow F_2^+$ and $F_2^+ + e \rightarrow F_2$, R^+ centers (F_3^+) form by the reaction $F_2 + \alpha \rightarrow F_3^+$ below 320°K and disappear slowly by the reactions $F_3^+ + e \rightarrow F_3$ and $F_3^+ + \text{heat} \rightarrow F_2 + \alpha$, above 330°K. Optical absorption band maxima at 80°K are: M^+, 1.22 eV (1015 nm); M_1, 1.74 eV (713 nm); R^+, 1.80 eV (690 nm); R_1, 2.28 eV (543 nm); and R_2, 2.07 eV (600 nm). N_1 and N_2 band systems were observed but were not studied in any detail. M^+ centers also were formed by direct ionization of M centers by 300-nm light. The concentration, however, was low because of a counterbalancing of photoionization and electron capture processes. R^+ centers were formed in x-irradiated NaCl by excitation with light absorbed in the R_2 band. They could be transformed back to R centers by x irradiation or F center bleaching. (auth)

59153 EVIDENCE FOR STATIC CROWDIONS IN ELECTRON-IRRADIATED Au-15 AT. PERCENT Ag ALLOYS. **Schuele, W. (EURATOM, Ispra, Italy); Frank, W.; Seeger, A. Radiat. Eff.; 10: No. 1-2, 123-7(Jul 1971).**

It is shown that recent investigations by Sprušil, Haas, and Wollenberger on the low-temperature electron irradiation and the recovery of the electrical resistivity of Au−15 at.% Ag alloys may be easily explained in terms of the two interstitial model. These results indicate in a rather specific way that, in this alloy, defect migration in stage I takes place one-dimensionally. It is concluded that none of the models that assume three-dimensional migration for the interstitial migrating at low temperatures are capable to account for the recovery behavior of Au−15 at.% Ag alloys. (auth)

59154 EFFECT OF NEUTRON AND ALPHA-PARTICLE IRRADIATION UPON THE PHYSICAL PROPERTIES OF α-SiC. Barinov, Y. V.; Bulgakov, Y. V.; Iglitsyn, M. I.; (and others) (Giredmet, Moscow). Radiat. Eff.; 10: No. 1-2, 111-15(Jul 1971).

Alpha-particle (25 MeV) and neutron irradiation of sublimation-grown α-SiC was carried out. A new EPR spectrum was observed but no model was established for the defect responsible for this spectrum. IR absorption (0.4 to 25 μ) was also studied; no distinct bands were observed beyond a broad near-edge nonselective absorption. (auth)

59155 INFRARED ABSORPTION STUDIES IN NEUTRON- AND ELECTRON-IRRADIATED GaAs. **Vaidyanathan, K. V.; Watt, L. A. K. (Univ. of Waterloo, Ont.). Radiat. Eff.; 10: No. 1-2, 99-106(Jul 1971).**

Mechanically and chemically polished samples of GaAs were irradiated with fission neutrons to fluences varying from 2×10^{16} to 1.4×10^{18} neutrons/cm^2 and with 1.5-MeV electrons with doses varying from 10^{17} to 10^{18} el/cm^2. Infrared absorption in irradiated crystals was measured at 300 and 85°K. In neutron-irradiated samples absorption bands centered at 0.47 eV and at 0.25 eV were observable. It is suggested that the 0.47 eV band is connected with transitions from a level at ($E_c - 0.5$) eV reported earlier from electrical measurements. The absorption coefficient was found to vary linearly with the square of the photon energy over a limited energy range. For electron-irradiated GaAs, the absorption in the band gap had an exponential variation with energy. Possible reasons for such a behavior are discussed. The absorption spectrum at 85°K in electron-irradiated samples showed the presence of a band at 1.0 eV. Isothermal and isochronal annealing behavior of this absorption band was studied. An analysis of data suggests that the recovery obeys first order kinetics with an activation energy of 0.88 ± 0.07 eV. (auth)

59156 ANNEALING BEHAVIOR OF BULK n-GaAs IRRADIATED BY ELECTRONS AT 77°K. **Jeong, M. U.; Shirafuji, J.; Inuishi, Y. (Osaka Univ.). Radiat. Eff.; 10: No. 1-2, 93-8 (Jul 1971).**

The annealing behavior of electrical properties and photoluminescence spectra both at 77°K in electron-irradiated melt-grown n-GaAs were investigated. Defects electrically active in the Hall mobility and carrier removal anneal through two stages centered at 250 and 460°K. From the temperature dependence of carrier concentration the existence of a defect level located near 0.15 eV below the conduction band is supposed. Several emission bands are resolved at 1.51, 1.47, 1.415, 1.305, and ~1.2 eV in photoluminescence experiments. Electron irradiation (1.5 to 2.0 MeV) caused a remarkable decrease in emission intensity of 1.51 and ~1.2 eV bands. Recovery of emission intensity occurred remarkably when samples were annealed to 520°K, which would correspond to the 460°K annealing stage for carrier concentration and Hall mobility. The 250°K annealing stage was not observed in photoluminescence experiments. The 1.415-eV peak appeared clearly after irradiation and grew remarkably with the 520°K annealing, especially in Si-doped samples, resulting in large reverse annealing. This band was tentatively speculated to be a complex of Si on As site with As vacancy. Moreover, in samples doped with Te a new emission band at 1.305 eV (9500 Å) was observed after 470 to 620°K annealing. (auth)

59157 COMMENTS ON THE SCATTERING OF CHARGED PARTICLES BY SINGLE CRYSTALS. I. THE GENERAL CASE. **Newton, C. S. (Oersted Inst., Copenhagen); Chadderton, L. T. Radiat. Eff.; 10: No. 1-2, 33-42(Jul 1971).**

The scattering of a beam of fast charged particles by a single crystal lattice is discussed in detail and a qualitative picture drawn of the quantum/classical transition. (auth)

59158 INFLUENCE OF THE DOSE OF IRRADIATION ON THE RECOVERY OF RESISTIVITY OF α IRRADIATED Al FOILS. **Trieb, L.; Siebinger, K. (Univ., Vienna). Z. Metallk., 62: No. 9, 682-4(Sep 1971). (In German).**

Technically pure Al foils (99.5%; main impurities 0.24% Fe, 0.09% Si, of 5.5 μm thickness) were irradiated with α particles from ^{210}Po at 78°K and the changes in electrical resistivity were measured. Three discrete recovery stages were found whose centers occurred at 115 and 160°K (stage II) and 220°K (stage III), respectively. The activation energy of stage III was found to be E = 0.58 eV. Details of the recovery curves resembled those of neutron irradiated specimens. (auth)

59159 PROCESSES OF FORMATION AND ANNEALING OF RADIATION DEFECTS IN GERMANIUM, IRRADIATED BY HIGH ENERGY PROTONS. **Konopleva, R. F.; Novikov, S. R.; Rubinova, E. E. (Ioffe Inst. of Physics and Tech., Leningrad). Radiat. Eff.; 10: No. 1-2, 117-22(Jul 1971).**

The rate of damage formation, the spectrum of energy levels, and the annealing results on n- and p-type Ge irradiated by 600-MeV protons were studied and compared to similar results on

γ-irradiated samples. Reverse annealing (and defect creation) was found upon the decay of disordered regions. The formation upon annealing of complexes with impurities is also deduced. (auth)

59160 STIRLING CYCLE CRYOGENIC COOLER USED WITH ACCELERATOR FOR RADIATION EFFECTS IN THIN FILMS. Pronko, P. P.; Hardy, W. R.; Shewchun, J. (McMaster Univ., Hamilton, Ont.). Radiat. Eff.; 10: No. 1-2, 79-85(Jul 1971).

A new approach is presented relating to the adaptation of a miniature closed-cycle cooler and its associated control equipment to accelerator-produced low-temperature radiation effects in solids. The cooler is capable of operating between 20 and 300°K with temperature control of 0.02°K within this interval. The system has been used with beams of 150-keV protons on thin films of oxygen- and nitrogen-doped tantalum, where changes in film conductance are used as a measure of the damage effects. A description of the cryogenic system is presented along with operational characteristics. Typical results are also presented for conductivity–fluence measurements, isochronal annealing, and radiation effects on temperature coefficient of resistivity. (auth)

59161 RADIATION EFFECTS IN CdTe INDUCED BY THERMAL NEUTRONS AND 1 MeV ELECTRONS. Abramov, A. A.; Vavilov, V. S.; Vodopyanov, L. K. (Lebedev Inst. of Physics, Moscow). Radiat. Eff.; 10: No. 1-2, 107-10(Jul 1971).

Neutron and electron bombardments of n- and p-type CdTe were carried out. Carrier concentration, Hall mobility, and photoconductivity were measured. Energy levels at $E_c - 0.06$ eV and $E_v + 0.17$ eV were found and are attributed to complicated centers, including the Cd vacancy. (auth)

59162 COMMENT ON EVIDENCE FOR STATIC CROWDIONS IN ELECTRON-IRRADIATED Au-15 AT. PERCENT Ag ALLOYS BY W. SCHUELE, W. FRANK, AND A. SEEGER. Wollenberger, H. (Kernforschungsanlage, Juelich, Ger. Technische Hochschule, Aachen). Radiat. Eff.; 10: No. 1-2, 135-6(Jul 1971).

Further comments are added to the earlier paper of the authors (Radiat. Eff., 10: 123-7(1971)). These comments discuss disordering, alloying effects, trapping role of Ag, defect migration, etc. One of the three recovery models cannot explain the recovery behavior of electron-irradiated Au−15 at.% Ag alloys. (D.L.C.)

59163 INTERACTION BETWEEN RADIATION DAMAGE AND COHERENT PRECIPITATES. Woolhouse, G. R.; Ipohorski, M. (Cavendish Lab., Cambridge, Eng.). Proc. Roy. Soc. (London), Ser. A; 324: No. 1559, 415-31(21 Sep 1971).

The experiments of Brown, Woolhouse, and Valdrè (Phil. Mag., 17: 781(1968)) on coherency loss induced by fast-neutron irradiation were extended by varying the precipitate size distribution, the fast-neutron dose, and the mismatch of the precipitate. When the integrated dose and the mean precipitate size are large, coherency loss is extensive during irradiation. Otherwise, thermal activation is required for coherency loss. This is shown to be consistent with a process involving the unfaulting of interstitial dislocation loops and their subsequent glide and climb to the precipitate interfaces. Closer agreement is found with the theoretically predicted critical size for coherency loss of Brown et al. Experiments involving coherency loss by electron irradiation in a high-voltage electron microscope are also described. It is found that, in this case, coherency loss occurs by the migration of free interstitial atoms produced by the irradiation and very close agreement with the theoretically predicted size is found. (auth) (UK)

59164 EFFECTS OF PRIOR ELECTROLYSIS ON THE KINETICS OF F-CENTRE GROWTH IN IRRADIATED NaCl. Montojo, M. T.; Jaque, F. (Junta de Energia Nuclear, Madrid). Solid State Commun.; 9: No. 18, 1595-7(15 Sep 1971).

NaCl crystals subjected to an electric field at high temperatures were subsequently irradiated with γ rays at room temperature. It was found that the first stage of the F curve was not affected while the length of stage II decreased and the coloring corresponding to stage III increased appreciably. This effect can be attributed to creation of nuclei for interstitial aggregation during the electrolytic treatment. (auth) (UK)

59165 CHANNELING. Thompson, M. W. (Univ. of Sussex, Brighton, Eng.). pp 223-36 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

A general review of channeling and blocking phenomena includes basic explanations and illustrations of the phenomena, diagrams of typical experiments, and brief discussions of classical and quantum mechanical theories of channeling. (A.G.W.)

59166 INTRODUCTION TO ION IMPLANTATION. Davies, J. A. (Univ. of Aarhus, Denmark). pp 237-66 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Existing experimental techniques for range measurements in ion implantation and the particular advantages and limitations of each are reviewed. Existing range data in amorphous and crystalline targets are summarized and correlated with theory wherever possible. The role of channeling in ion implantation in monocrystalline targets is considered. Anomalous penetration effects due to various types of enhanced-diffusion processes are discussed briefly. (58 references) (A.G.W.)

59167 CHANNELING-EFFECT TECHNIQUE FOR STUDYING ATOMIC LOCATIONS WITHIN THE CRYSTAL LATTICE. Davies, J. A. (Univ. of Aarhus, Denmark). pp 267-95 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

The general principles of the channeling phenomenon are reviewed. Techniques for application of channeling as a tool for determination of the amount of lattice disorder in crystals and the distribution of implanted atoms between substitutional and various interstitial sites are discussed. A brief summary of results of such studies is included. (30 references) (A.G.W.)

59168 ION IMPLANTATION OF BINARY III–V SEMICONDUCTORS. Carter, G.; Aiers, M.; Grant, W. A.; (and others). (Univ. of Salford, Eng.). pp 296-325 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

Studies of the basic physical parameters involved in effective ion implantation of binary III–V semiconductors are reviewed. These studies deal with depth profiles of implanted ions, the nature and extent of the radiation damage created by implantation, the possibilities of minimizing this radiation damage, and the location of implanted ions within the lattice. Electrical behavior of implanted materials is discussed briefly. (37 references) (A.G.W.)

59169 DECHANNELING OF PARTICLES BY LATTICE DEFECTS. Quere, Y. (CEN, Fontenay-aux-Roses, France). pp 392-407 of Physics of Ionized Gases. /Navinsek, B. (ed.). Ljubljana, Yugoslavia; Institut Jozef Stefan (1970).

From 5th Plasma Physics Symposium, Hercegnovi, Yugoslavia. See CONF-700706.

All lattice defects tend to dechannel channeled particles. The dechanneling probability is generally a function of the energy of the channeled particle, of the distance to the defect, and of the family of axial (or planar) channels involved. Some theoretical predictions are given in the case of dislocations and stacking faults. Experimental evidences of dechanneling are presented for boundaries, dislocations, stacking faults, Guinier–Preston zones, etc. (auth)

59170 ACCUMULATION OF RADIATION DEFECTS IN RADIOACTIVE SAMPLES. Gromov, V. V. (Inst. of Physical Chemistry, Moscow). High Energy Chem. (USSR) (Engl. Transl.); 3: No. 5, 400(Sep-Oct 1969).

Translated from Khim. Vys. Energ.; 3: No. 5, 444-5(Sep-Oct 1969).

Under the action of self-radiation in radioactive solid bodies various defects accumulate, such as radical ions, color centers, and dislocated atoms. Analogous changes also occur during the external irradiation of nonradioactive samples. However, in the former case, the self-radiation intensity (the quantity of radioactive isotope) can change significantly with time, which must substantially affect the kinetics of radiation-defect accumulation. Formulation is given for a case when the accumulation and annealing of radiation dislocations is a monomolecular process in which the intensity of irradiators varies according to an expression relating the dislocation concentration to time. (auth)

59171 DISORDER PRODUCED IN SiC BY ION BOMBARDMENT. Hart, R. R.; Dunlap, H. L.; Marsh, O. J. (Hughes Research Labs., Malibu, Calif.). Radiat. Eff.; 9: No. 3-4, 261-6(Jun 1971). (CONF-700824-50).

XUM

From International conference on radiation effects and semiconductors; Albany, N. Y. (24 Aug 1970).

The amount of residual lattice disorder produced in $\alpha-$SiC after implantation of 40-keV Sb^+ and 30-keV N^+ was measured. The implantations were performed at 23°C and, to avoid channeling effects, at a preselected random-equivalent orientation of the target with respect to the ion beam. The disorder, defined as the number of lattice atoms displaced greater than ~0.2Å from lattice sites, was determined by backscattered energy analysis of 280-keV He^{2+} and 140-keV H^+ incident along the ⟨0001⟩ channel and in a random direction. The amount of disorder increased linearly with dose of the heavy ion (Sb^+) to a saturation condition, corresponding to the formation of an amorphous layer at a dose of $\sim 10^{14}$ Sb^+/cm^2. The disorder produced by the light ion (N^+) at first increased as the square root of N^+ dose but at $\sim 10^{14}$ N^+/cm^2 increased approximately linearly with dose to a saturation value at $\sim 10^{15}$ N^+/cm^2. Similar behavior for these two ions has been observed in Si. The number of displaced atoms of Si and C produced by an Sb ion is ≈2400. Comparison of this result with Sb ion displacement in Si indicates a displacement energy E_d for SiC for 17- to 30-eV. A significant annealing of lightly disordered regions in the Sb^+ and N^+ implanted layers is observed after 500°C. More heavily damaged layers anneal at 750°C and above. Little disorder remains after a 1200°C anneal. Annealing at 1650°C or greater produces evidence of decomposition, although there are indications that the implanted species inhibits further decomposition. There is no evidence of outdiffusion of Tl after 1650°C anneal and only slight evidence of outdiffusion of Sb after 1700°C anneal. Channeling analysis of Sb^+ implants after a 1500°C anneal that ~50% of the Sb ions are located along the ⟨0001⟩ atomic rows. (auth)

59172 ELECTRIC CONDUCTIVITY OF ELECTRON-IRRADIATED MONOCRYSTALS OF KCl–RbCl SOLID SOLUTIONS. Zavadovskaya, E. K.; Grishukov, V. A.; Cholokov, K. S. (Tomsk Polytechnic Inst., USSR). Izv. Vyssh. Ucheb. Zaved., Fiz.; No. 12, 92-6(1970). (In Russian).

The influence of divalent cation impurities on the radiation-induced changes of electric conductivity of RbCl crystals and KCl−RbCl solid solutions when irradiated by 1.2-MeV electrons of current strength 1.86 to 7.44 × 10^{15} el/cm^2 was studied. It was found that at 20 to 550°C, the temperature dependence of electric conductivity has, in general, a complex form. In the case of crystals free of divalent impurities, not only is the radiation decrease of conductivity from the Smoluchowski mechanism absent, but there is observed a sharp increase. The physical processes that lead to the appearance of maxima in the temperature dependence of electric conductivity of irradiated crystals are considered. (tr-auth)

59173 EFFECT OF ION BOMBARDMENT ON SEMICONDUCTORS. Abroyan, I. A. (Leningrad Polytechnic Inst.). Usp. Fiz. Nauk; 104: No. 1, 15-50(May 1971). (In Russian).

Change in physical properties of semiconductors resulting from ion bombardment and introduction of various types of defects are reviewed. Types of defects and methods of investigating structural disturbances in semiconductors are described. The bulk of the discussion is concerned with changes in the electrical properties by ion bombardment: creation of p−n junctions, electric conductivity of layers obtained by ionic alloying, and diffusion occurring during irradiation. Radiation conductivity and luminescence during bombardment with electrons and ions and effects on optical and other properties are included. 217 references. (K.S.W.)

59174 ELECTRON SPIN RESONANCE STUDIES OF INTRINSIC AND IMPURITY DEFECTS IN SILICA AND GERMANIA. Garlick, G. F. J.; Nicholls, J. E.; Prasad, C.; Oezer, A. M. (Univ. of Hull, Eng.). Phys. Chem. Glasses; 12: No. 4, 102-4(Aug 1971).

The occurrence of electron spin resonance due to intrinsic defects in silica and germanium was investigated by other workers. In the present studies the effects of heat treatment in controlled ambients on impurities caused by high-energy electron bombardment were investigated using spin resonance and thermal annealing techniques. A new center was found in silica doped with hydrogen involving an electron trapped at a silicon site with an adjacent hydrogen atom which imposes a characteristic hyperfine structure. In germanium dioxide, centers due to oxygen vacancy−interstitial oxygen pairs with an associated impurity ion were found. Threshold energies for displacement of network oxygen were determined by high-energy electron bombardment. Electron spin resonance signals characteristic of intrinsic and impurity defects in silica and in zinc oxide were used to follow the transfer or removal of these defects when the two oxides were used to synthesise zinc orthosilicate. Such techniques offer a powerful tool in the study of such syntheses and may be extended to follow the stages of formation of silicate glasses and crystals. (auth) (UK)

59175 AMORPHIZATION OF CRYSTALS BY ION BOMBARDMENT AND MECHANISMS OF SECONDARY PROCESSES. Sommerfeldt, H.; Mashkova, E. S.; Molchanov, V. A. (Moscow State Univ.). Radiat. Eff.; 9: No. 3-4, 267-71(Jun 1971). (In German).

Results of an experimental study of the ion−electron-emission coefficient of monocrystalline and amorphous germanium as a function of the angle of incidence for 10 to 30-keV Ne^+, Ar^+, Kr^+ ions are presented. Using the concept of ion channeling in crystals, the energy dependence of anisotropy of the ion−electron-emission coefficient is explained. (auth)

Physical Properties

59176 MAGNETIC PROPERTIES OF Sm–Gd ALLOYS. Shafigullina, G. A.; Chechernikov, V. I.; Torchinova, R. S. (Moscow Univ.). Fiz. Metal. Metalloved.; 31: No. 1, 217-19(Jan 1971). (In Russian).

Magnetic properties of alloys prepared from Sm and Gd were investigated in the temperature range 77 to 1100°K. The Sm-rich alloys possessed a low-temperature anomaly in magnetic susceptibility and, in the paramagnetic region, exhibited a complex temperature dependence of the susceptibility. The magnetic properties of the Gd-rich alloys resulted from a localization of the 4f electrons. (K.S.W.)

59177 THERMOEMISSIVE PROPERTIES OF A SPHERICAL MONOCRYSTAL OF TANTALUM. Azizov, U. V.; Karabaev, T. A.; Mukhailov, S. M. (Tashkent State Univ.). Izv. Akad. Nauk Uzb. SSR, Ser. Fiz.-Mat. Nauk; No. 2, 66-7(1971). (In Russian).

Emission patterns were prepared from a pure monocrystal of Ta and of the system $Ba-Ta_{hkl}$. The Ta had the same body centered cubic lattice as W, Mo, and Nb, and its emission pattern was also similar. Barium was sputtered onto a Ta surface and the work function of this system was investigated. (K.S.W.)

59178 X-RAY SPECTRA AND ENERGY BAND SCHEMES OF BeO AND BN. Fomichev, V. A. (Leningrad State Univ.). Sov. Phys.-Solid State (Engl. Transl.); 13: No. 3, 754-6(Sep 1971).

Translated from Fiz. Tverd. Tela; 13: No. 3, 907-9(Mar 1971).

The x-ray emission and absorption spectra of the atomic components of BeO and BN were used to refine the electron band structure. The spectra were arranged so that they coincide at the Fermi level. For BeO, the widths of the forbidden and valence bands are 7.8 and 10.3 eV; for BN, they are 3.6 and 14.0 eV. The maxima of the valence bands are in good agreement with the most important peaks in the x-ray emission spectra of the components. (D.L.C.)

59179 TEMPERATURE DEPENDENCES OF THE DEBYE–WALLER FACTORS OF Zr, Nb, AND Mo. Korsunskii, M. I.; Genkin, Ya. E.; Vigdorchuk, L. I. (Inst. of Nuclear Physics, Alma-Ata, USSR). Sov. Phys -Solid State (Engl. Transl.); 13: No. 3, 761-2(Sep 1971).

Translated from Fiz. Tverd. Tela; 13: No. 3, 913-14(Mar 1971).

The reduced Debye−Waller factor M′ was measured at 90 to 400°K for reflections from the (123), (025), and (220) planes of $\alpha-$Zr, the (321) planes of Nb, and the (321) and (222) planes of Mo. The inequality $M'_{Zr} > M'_{Nb} > M'_{Mo}$ was found over the entire temperature range and was correlated with the melting point, strength of local orbitals, and shear moduli, but not with the sublimation heat. (D.L.C.)

59180 MAGNETIC SPECIFIC HEAT AND SPIN DISORDER RESISTIVITY OF URANIUM MONONITRIDE IN A 5 f^2 CONFIGURATION MODEL. de Novion, C. H. (CEN, Fontenay-aux-Roses, France). Compt. Rend., Ser. B; 273: No. 1, 26-9(5 Jul 1971). (In French).

The magnetic specific heat of UN is calculated in the molecular field approximation, assuming that the magnetic moments are those of a 5 f^2 configuration submitted to an octahedral crystal field. The effect of the crystal field on the spin-disorder resistivity is calculated for the paramagnetic state. (France)

59181 GADOLINIUM MAGNETIC EQUATION OF STATE NEAR THE CURIE POINT. Deschizeaux, M. N.; Develey, G. (Institue Polytechnique, Grenoble, France). J. Phys. (Paris); 32: No. 4, 319-23(Apr 1971). (In French).

From the magnetization field−temperature dependence of a gadolinium monocrystal near the Curie point, the critical exponents of the spontaneous magnetization, of the initial paramagnetic susceptibility, and of the critical isotherm is determined. An equation of state that defines the transition near T_c is given. (France)

59182 ELECTRIC PROPERTIES OF ALLOYS OF LANTHANUM HEXABORIDE WITH TRANSITION METALS. I. Bondarenko, V. P.; Kovenskaya, B. A.; Morozov, V. V. (Kiev Polytechnic Inst.). Izv. Vyssh. Ucheb. Zaved., Fiz.; No. 2, 12-15 (1970). (In Russian).

The effect of Hf, W, Ta, and Re additions on the electrical properties of lanthanum hexaboride was studied, and results are given of the measurement of electrical resistance, thermo-e.m.f., and Hall effect. The addition of 0.5 at.% Hf and W resulted in a sharp (up to 20 to 25%) decrease in the electrical resistance. It was found that the sudden reduction in resistance and thermo-e.m.f. was caused by redistribution of electron density and change in mobility on the formation of solid solutions. (D.H.M.)

59183 TEMPERATURE DEPENDENCE OF ELECTROPHYSICAL PROPERTIES OF ALLOYS OF LaB_6 WITH TRANSITION METALS. II. Bondarenko, V. P.; Kovenskaya, B. A. (Kiev Polytechnic Inst.). Izv. Vyssh. Ucheb. Zaved., Fiz.; No. 2, 90-3(1970). (In Russian).

The temperature dependence of electrical resistance is investigated in alloys of lanthanum hexaboride with additions (0.5, 1, 5, 10, and 15 at. %) of transition metals (Hf, Ta, W, Re). It is shown that the thermal coefficient of resistance of solid solutions of these metals with lanthanum hexaboride is determined by the properties of the dissolved metal, and on this basis the weakening of interatomic bonds in the series of solid solutions LaB_6 + 0.5% W, LaB_6 + 0.5% Re, LaB_6 + 0.5% Ta, and LaB_6 + 0.5% Hf is discussed. Data on the thermo-e.m.f. of these alloys are also given. (TSS)

59184 COMPARATIVE STUDY OF THE RELATION BETWEEN THE ELECTRIC CONDUCTIVITY AND GRAIN SIZE IN SINTERED URANIUM DIOXIDE. Rubio, Andre (CEN, Saclay, France). Compt. Rend., Ser. B; 272: No. 25, 1435-8(21 Jun 1971). (In French).

Room-temperature measurements of the electric conductivity of stoichiometric sintered UO_2 samples demonstrated that the electric resistivity varies as the reciprocal of the grain size. This result is associated with the UO_2 microstructure after sintering or heating under a strong temperature gradient. The grain growth occurring is associated with a decrease in porosity; density measurements demonstrated that the resistivity is an inverse function of the density. (France)

59185 EFFECT OF THORIUM ON Ce^{+3} PHOSPHORS. Hoffman, Mary V. (General Electric Co., Cleveland). J. Electrochem. Soc.; 118: No. 9, 1508-10(Sep 1971).

The effects of Th^{4+} on the Ce^{3+} and Tb^{3+} emission peaks in $CePO_4$ and $LaPO_4$ matrices were studied. The effects were found to be that of enhancement, and the composition effects of Th, Tb, and Ce were studied. The role of Th^{4+} in the enhancement of Ce^{3+} and Tb^{3+} emission in the monazite lattice is not energy transfer but valence control of the Ce ion (removal of Ce^{4+} ions). Decay and reflectance measurements which support this conclusion are reported. (D.L.C.)

59186 ELECTRICAL RESISTANCE AND STRUCTURE OF FILMS OF TUNGSTEN, MOLYBDENUM, AND CHROMIUM PRODUCED BY LASER EVAPORATION. Bondarenko, B. V.; Shchuka, A. A. (Moscow Physical-Technical Inst.). Fiz. Metal. Metalloved.; 30: No. 1, 207-10(Jul 1970). (In Russian).

Thin W, Mo, and Cr films were obtained by laser evaporation from the bulk metals and their electrical resistances were determined and correlated with film structure. Typical values of the specific electrical resistance of massive samples at 20°C were 4.9, 5.2, and 12.7 (in $10^{-6}\ \Omega \cdot cm$) for W, Mo, and Cr, respectively, whereas the corresponding values for the thin films were 360, 165, and 130. The temperature coefficient of resistance, however, was much smaller for the thin films than for the massive samples. (Metals Abstr.)

59187 OPTICAL PROPERTIES OF GADOLINIUM, SAMARIUM, AND DYSPROSIUM IN THE SPECTRAL RANGE 1.13 TO 3.96 eV. Knyazev, Yu. V.; Noskov, M. M. (Inst. of Metal Physics, Kiev). Fiz. Metal. Metalloved.; 30: No. 1, 214-17(Jul 1970). (In Russian).

The dispersion of the optical constants (refractive index n and absorption coefficient k) of Sm, Gd, and Dy was studied at 20°C for the spectral range 1.13 to 3.96 eV; the light conductivity $nk\nu$ (ν = frequency) was calculated from the results. Plotted against energy, the light conductivity exhibited a nonmonotonic character, indicating that this range of energies constituted a range of quantum transitions. The possible nature of these transitions is considered. (Metals Abstr.)

59188 INVESTIGATION OF TERNARY SOLID SOLUTIONS $Ni_3(Fe,V)$. Sarkisyan, R. S.; Selisskii, Ya. P.; Sorokin, M. N. Fiz. Metal. Metalloved.; 30: No. 1, 47-53(Jul 1970). (In Russian).

The temperature dependence of Young's modulus, the kinetics of the changes in electrical resistance during heat treatment, and the temperature dependence of electrical resistance were studied in ternary Fe–Ni–V solid solutions of the $Ni_3(Fe, V)$ type, and the results were correlated with x-ray analysis results. With increasing V content the Young's modulus, the order–disorder transformation temperature and the electrical resistance increased, while the saturation magnetization and Curie point diminished. On annealing the samples and cooling them slowly, there was an additional increase in Young's modulus not found in the quenched material. (Metals Abstr.)

59189 TEMPERATURE DEPENDENT ELECTROSTATIC INTERACTIONS BETWEEN MAGNETIC IONS IN URANIUM MONOPHOSPHIDE. Long, Christopher Eugene. Tallahassee; Florida State Univ. (1970). 92p. University Microfilms Order No. 71-18,371.

Thesis.

An experimental and theoretical investigation of the anomalous temperature variation of the magnetization of uranium monophosphide has been carried out. Neutron-diffraction measurements indicate that the sublattice magnetization undergoes a sharp change from 1.95 to 1.72 Bohr magnetons per ion upon warming to about 23°K. The procedure and results of ^{31}P nuclear magnetic resonance experiments are described. An unsuccessful attempt to explain the anomaly using a molecular-field theory including crystal-field effects is described, and the inability of this theory to explain the anomaly is proven. The importance of temperature-dependent electrostatic interactions between the charge distributions of the magnetic electrons associated with neighboring ions is examined, and it is shown that they may have an important influence on the magnetic properties of a large class of compounds. These interactions are crudely approximated in the theory by a temperature-dependent quadrupole–quadrupole interaction between the magnetic electron charge densities, and the modified theory is shown to be in excellent agreement with experiment in the temperature range of the anomaly. The modified theory fails to produce the observed temperature dependence of the magnetization near the Neel transition. The magnetic susceptibility is calculated and found to disagree with experiment. Several possible reasons for the disagreement are advanced, and suggestions for further experimental and theoretical work are given. (Diss. Abstr. Int., B)

59190 MAGNETIC TRANSITION POINTS IN U_3Bi_4 AND UGa_2. Sternberk, J.; Ansorge, V.; Hrebik, J.; Menovsky, A.; Smetana, Z. (Charles Univ., Prague). Czech. J. Phys.; 21: No. 9, 969-78(1971).

Polycrystalline compounds U_3Bi_4 and UGa_2 in powder form have been investigated by the method of H/M vs M^2 curves to find well-defined values of the magnetic transition temperatures T_C. For $T > T_C$ the asymptotic transition points have been obtained by linear extrapolation of the $1/\chi$ vs T dependence. It has been found that, in contrast to other papers, the points T_C and Θ_C coincide within the limits of experimental errors (±2°K). On the absolute scale these points are T_C = 112°K for U_3Bi_4 and T_C = 126°K for UGa_2. (auth)

59191 STUDY OF THE ELECTRICAL CONDUCTIVITY AND THERMOELECTRIC POWER OF URANIUM DIOXIDE UO_{2+x} AT HIGH TEMPERATURES. Sorriaux, Andrea; Djerassi, Henri (CEN, Saclay, France). Compt. Rend., Ser. B; 272: No. 24, 1373-6(14 Jun 1971). (In French).

Measurements effected on $UO_{2\overset{+}{x}}$ between 300 and 1100°K established that the conductivity is proportional to $T^{-3/4}e^{(-0.36/2kT)}$ in this range. It was possible to estimate the width of the forbidden band (approximately 1.8 eV) between 1100 and 1500°K. An investigation of the thermoelectric power, α, demonstrated that UO_{2+x} behaves as a p-type semiconductor, a change of sign occurring above 1430°K. The activation energy associated with α was evaluated to be 0.17 eV. (France)

59192 RESOLVED FINE STRUCTURE IN THE MAGNETIC RESONANCE OF A LOCALIZED MOMENT IN A METAL. Chock, E. P.; Chui, R.; Davidov, D.; (and others). (Univ. of California, Los Angeles). Phys. Rev. Lett.; 27: No. 9, 582-6(30 Aug 1971).

The first observation of the resolved fine-structure splitting of a localized moment in a metal is reported in the EPR spectrum of single-crystal dilute Au:Gd alloys. A theory of line narrowing of fine-structure lines from spin–spin couplings and localized-conduction electron exchange is developed. The narrowing distorts the observed resonance line shape and is essential to the

XUM

extraction of the fine-structure splitting parameter: $b_4 = -20 \pm 1$ G. (auth)

59193 ELECTRICAL PROPERTIES OF La_2O_3–CaO, Y_2O_3–CaO, AND ZrO_2–CaO SOLID ELECTROLYTES. **Etsell, Thomas Harvey.** **Toronto; Univ. of Toronto (1969). National Library of Canada, Ottawa.**

Thesis.

I. At 1600°C, La_2O_3 can dissolve about 16 mole % CaO which leads to the creation of anion vacancies. No compounds are formed in this system. The electrical conductivities of pellets containing from 0 to 50 mole % CaO were measured at 400 to 1100°C under oxygen pressures of 1 to 10^{-21} atm at 1000°C. The defect solid solutions behave as oxygen anion conductors below an oxygen pressure of 10^{-7} atm. The maximum ionic conductivity, which is 2.4×10^{-2} ohms^{-1} cm^{-1} at 1000°C, was observed at the solubility limit. At high oxygen pressures, the appearance of p-type conductivity, proportional to $P_{O_2}^{1/4}$, results in a region of mixed conduction. The apparent activation energies for both ionic and p-type conduction are ~17-20 kcal/mole. N-type conductivity was not observed at low oxygen pressures. Even La_2O_3 exhibits predominantly ionic conduction at intermediate oxygen pressures. Several transport numbers were verified by emf measurements. II. Only 5 to 8 mole % CaO could be dissolved in Y_2O_3 at 1600°C. The solid solutions are solely ionic conductors only below an oxygen pressure of about 10^{-12} atm. The ionic conductivities are almost two orders of magnitude lower than those exhibited by the La_2O_3–CaO electrolytes. Again, the p-type conductivity at high oxygen pressures varied as $P_{O_2}^{1/4}$. Since the apparent activation energies for ionic and p-type conduction are ~25-30 and 36 kcal/mole, respectively, ionic transport numbers decrease with increasing temperature. The ionic contribution to the conductivity of Y_2O_3 is very small. III. The behavior of impervious ZrO_2–10 mole % CaO electrolyte tubes was studied at 500 to 1100°C in oxygen concentration cells of the type (–) Ar–O_2 or CO–CO_2/ZrO_2–CaO/O_2 (+). The equilibrium oxygen pressures imposed by Ar–O_2 (1 to 10^{-6} atm) and CO–CO_2 (10^{-6} to 10^{-18} atm at 1000°C) mixtures were determined. When currents are passed through the oxygen concentration cell, only resistance polarization is generally observed in the presence of Ar–O_2 mixtures, even at current densities of 250 mA/cm^2 and 1000°C. If Ar–O_2 mixtures dilute in O_2 are present at the cathode, concentration polarization arises. Limiting currents, proportional to P_{O_2}, are controlled by the diffusion of oxygen through the gas phase to the reaction sites. When the oxygen pressure at the cathode is reduced to $10^{-27.5}$ atm at 1000°C, a significant amount of electronic conductivity is introduced into the electrolyte. For CO–CO_2 mixtures, activation polarization was detected. Exchange current densities are about 1 mA/cm^2 at 850 to 1100°C. The polarization behavior of the cell (–) Ar–O_2, $\underline{O}$(in Ag)/ZrO_2–CaO/O_2 (+) where $\underline{O}$ represents dissolved oxygen was investigated at 1000 to 1200°C. When voltages are applied to the cell to reduce oxygen in the liquid silver, limiting currents, controlled by the diffusion of oxygen in the melt, can be observed. The limiting currents are directly proportional to the concentration of dissolved oxygen (or $P_{O_2}^{1/2}$) from 0.01 to 2.0 at. % oxygen. This technique could be used to analyze liquid metals for dissolved oxygen. (D.L.C.)

59194 SURFACE ENERGY AND WORK FUNCTION OF THE SMOOTH FACES OF A METALLIC SINGLE CRYSTAL. **Zadumkin, S. N.; Shebzukhova, I. G.; Al'chagirov, B. B. Fiz. Metal. Metalloved.; 30: No. 6, 1313-15(Dec 1970). (In Russian).**

Controversial existing theories as to the relationship between the surface energy and work function of smooth faces on metallic single crystals are discussed, and a fresh attempt at solving the problem is presented. A simple expression relating the specific surface energy of smooth metal-crystal faces to their work function is derived and compared with experiment for Ni, Nb, Ta, Mo, and W. Theoretical and experimental data agree in order of magnitude, although there are still appreciable differences requiring further discussion. (Metals Abstr.)

59195 LOW-TEMPERATURE ELECTRICAL RESISTIVITY OF YCe UNDER PRESSURE. Maple, M. B.; Wittig, J. (Univ. of California, San Diego). Solid State Commun.; 9: No. 18, 1611-15 (15 Sep 1971).

The magnitude of the low-temperature electrical resistivity anomaly associated with the Kondo effect in Y–1 at.% Ce decreased with pressure and disappeared altogether above ~80 kbar, suggesting that the Ce impurities become nonmagnetic at high pressure. The depression of the superconducting transition temperature of Y by 1 at.% Ce at high pressure may be accounted for by scattering of conduction electrons into nonmagnetic Ce4f resonant states. (auth) (UK)

59196 MOLECULAR FIELD STUDY OF THE ISOTOPIC EFFECT IN $KH_{2x}D_{2(1-x)}PO_4$ MIXED CRYSTALS. Kopsky, V. (Inst. of Physics, Prague). Czech. J. Phys.; 21: No. 8, 896-916(1971).

The theory of KDP and isomorphous crystals is developed, which takes into consideration possible difference in ferroelectric interactions between pairs of H bonds with deuteration. It is shown why the interaction should differ from pairs of H–H, D–D, and H–D isotopes. Expressions for the transition temperature and static susceptibility above it are derived by approximating the molecular field acting on a proton (deuteron) by the field of the average surrounding. The theory results in a linear dependence of the asymptotical transition temperature and the Curie–Weiss constant on concentration. For the actual $T_c(x)$ also a linear dependence was found under the condition that tunneling is small, the distribution of H, D isotopes over H bonds is quite random, and that the interaction between isotopes is of purely dipolar character. Modifications of the linear dependence due to ordering and deviations of the interaction from dipolar are found. It is further suggested, as a result of comparison with recently performed measurements of pressure dependence of the transition point, that the main part of the isotopic shift of the transition point is due to the difference in H–H and D–D coupling, whereas the tunneling contributes by a relatively small amount. 59197 COBALT-RICH DUCTILE PERMANENT MAGNET ALLOYS WITH MOLYBDENUM ADDITIONS. **Steinitz, Robert (Wilbur B. Driver Co., Newark, N. J.). Met. Trans.; 2: No. 10, 2813-16(Oct 1971).**

The class of semihard permanent magnet compositions has been extended to compositions containing molybdenum. Under suitable conditions, these alloys can develop higher coercive forces (>100 Oe) and energy products (about 0.5×10^6) than could be obtained in similar materials before, but they can readily be worked to fine wires (5 mil or less). Coercive forces below the maximum can, of course, be arrived at by adjusting time and temperature of the aging treatment. Over 7% Mo was added to Co–Fe alloys; part of the molybdenum could be replaced by titanium. Cold work is necessary to develop precipitation within reasonable times. The new alloys are compared on the basis of their coercive force, residual magnetism, and squareness of the hysteresis curve. (auth)

59198 LOW-TEMPERATURE MAGNETIC BEHAVIOR OF SEVERAL OXIDES OF GADOLINIUM. **Miller, A. E.; Jelinek, F. J.; Gschneidner, K. A. Jr.; Gerstein, B. C. (Iowa State Univ., Ames). J. Chem. Phys.; 55: No. 6, 2647-8(15 Sep 1971).**

The low-temperature magnetic susceptibility, at 1 to 6°K, of the monoclinic and cubic, stoichiometric, and substoichiometric Gd_2O_3 phases are reported. The magnetic transformation temperatures were determined, and those of the substoichiometric phases probably give rise to the specific heat peaks observed in Gd metal containing appreciable amounts of oxygen. (auth)

59199 (NYO-2150-74) HINDERED ROTATION AT 2°K OF THE NO_2 IMPURITY IN KCl. **Bojko, Ignacy; Silsbee, R. H. (Cornell Univ., Ithaca, N. Y. Materials Science Center). Jun 1971. 40p. Dep. NTIS.**

The electron spin resonance of the NO_2 molecule incorporated as an impurity in KCl (produced by x irradiation of KNO_2 dopant) is studied in the temperature range 1.6 to 10°K and as a function of applied uniaxial stress at 1.8 and 4.2°K. The results are interpreted in terms of a model in which the molecule is assumed to be in uniaxial hindered rotation, with the first excitation energy, or tunneling splitting, estimated to be about 3 cm^{-1}, to be compared with a free rotational excitation energy of 8 cm^{-1}. Because the hindering potential is only moderate, it is necessary to include the effect of the molecular spin rotational coupling in developing a satisfactory spin hamiltonian to describe this system. (auth)

59200 ^{153}Eu INDIRECT SPIN–SPIN INTERACTION AND INHOMOGENEOUS LINE BROADENING IN FERROMAGNETIC EuO. **Barak, J.; Siegelstein, I.; Gabai, A.; Kaplan, N. (Hebrew Univ., Jerusalem). Phys. Rev. Lett.; 27: No. 12, 817-20(20 Sep 1971).**

The transverse relaxation rate of ^{153}Eu in EuO, caused by the indirect Suhl–Nakamura interaction, was calculated and measured. The results confirm the validity of a theoretical model developed recently to treat inhomogeneously broadened NMR lines. The local variation of the ^{153}Eu hyperfine field is determined and interpreted in terms of a local strain. (auth)

59201 ESR INVESTIGATION OF $3d^9$ IONS IN ALKALI HALIDES. Kuwabara, Goro (Tokyo Univ.). J. Phys. Soc. Jap.; 31: No. 4, 1074-84(Oct 1971).

Cu^{2+} in NaCl, LiCl, and NaF, and Ni^+ in NaCl, most of which were produced from Cu^+ and Ni^{2+} by x irradiation were studied by means of ESR. All of Cu^{2+} had elongated tetragonal surroundings, while Ni^+ had compressed ones. In $NaCl:Cu^{2+}$, the optical dichroism along a cube edge was detected at 5°K corresponding to the Jahn–Teller distortion. From the observed super hyperfine structure of surrounding nuclei, the amounts of covalency, f_s and f_σ were estimated as 0.77 to 0.89% and 7.9 to 12% in the chlorides, respectively. In the case of $NaCl:Cu^{2+}$ doped as divalent state, sharp anisotropic spectra outside the hyperfine structure due to Cu nucleus were observed, presumably due to coagulated ions. (auth)

59202 NUCLEAR SPIN RELAXATION STUDIES IN SOLID AND LIQUID DEUTERIUM. Wang, Richard Yuan-chang. Philadelphia; Univ. of Pennsylvania (1970). 211p. University Microfilms Order No. 71-19,296.

Thesis.

Pulsed NMR experiments in solid and liquid deuterium were performed over the temperature range 9 to 21°K. The spin–lattice relaxation times of a number of ortho–para compositions were measured as a function of temperature. The self-diffusion coefficients and activation energies were also reported. A kinetic model was proposed to account for the observations by making use of existing theories of spin–lattice and spin–spin relaxations. The dominated mechanisms for the relaxation of para-D_2 ($J = 1, I = 1$) and ortho-D_2 ($J = 0, I = 2, 0$) are (i) intramolecular interactions of $J = 1$ molecules (p-D_2) modulated by the anisotropic intermolecular quadrupolar interaction; (ii) intermolecular dipolar interaction which provides (a) a diffusion relaxation process, and (b) a cross relaxation process. The experiments and theory are in good agreement. (Diss. Abstr. Int., B)

59203 NEW MOESSBAUER ^{57}Co SOURCES. Godovikov, S. K.; Kuz'min, R. N. (Moscow State Univ.). Vestn. Mosk. Univ., Ser. III. Fiz. Astron.; 12: No. 2, 220-1(Mar-Apr 1971). (In Russian).

Efforts to prepare a source containing ^{57}Co employed low-level (about 0.1 μ Ci/cm^2) mixtures containing a small amount of ^{57}Co in stable Co. The sources investigated were CoAl, CoBe, Co–25 at.% Cr, and Co–80 at.% Rh, and the pertinent parameters were measured as applicable to the Moessbauer effect. All alloys prepared were kept within the limits 20 to 30 mg, and the absence of an extraneous phase was confirmed with x-ray analysis. (K.S.W.)

59205 (JINR–E2-6043) APPROXIMATE METHODS FOR SOLVING SCHROEDINGER EQUATION WITH MARGINALLY SINGULAR POTENTIAL. Filippov, A. T.; Gogokhiya, V. S. (Joint Inst. for Nuclear Research, Dubna (USSR). Lab. of Theoretical Physics). 1971. 17p. Dep. NTIS (U. S. Sales Only).

The renormalization theory for the Schroedinger equation with marginally singular potentials is outlined. The singular potentials are shown to be classified naturally into renormalizable and nonrenormalizable ones by the structure of the perturbative series (with a small-distance cutoff) analogous to that of field theories. Approximate methods for solving the Schroedinger equation with the singular potential $g_0V(r)$ are discussed. These enable one to find the wave function as a series of powers of $g_0^\nu(\ln g_0)^n$, where n is an integer and ν is generally a noninteger (a modified perturbation theory). The most powerful method for constructing such a series is the "asymptotic" perturbation theory in which the first approximation for the wave function has the exact asymptotic behavior for $r = 0$. (auth)

59206 (LYCEN–7118) NON-EXHAUSTIVE RESTATEMENT OF THE ANGULAR MOMENTUM REDUCTION IN THE THREE-BODY PROBLEM. El Baz, E.; Fayard, C.; Lamot, G.-H.; Pigeon, J. (Lyon Univ. (France). Institut de Physique Nucleaire). Apr 1971. 26p. Dep. NTIS (U. S. Sales Only).

A brief description is given of the formalisms currently used for angular momentum reduction in the three-body problem. The Omnes symmetrical method is restated. Three unsymmetrical methods derived from Ahmadzadeh and Tjon's work are then presented. In the first one, due to Grubman, a particular determination of the body-fixed axis is used. The second method utilizes the expansion of a spherical harmonic, the argument of which is the sum of two vectors. The third method starts from the Faddeev–Lovelace formalism and also utilizes the expansion of a spherical harmonic. A comparison between these methods is made for the special case (n–d). (France)

59207 (NP–19033) ELEMENTARY SOLUTIONS OF THE SCHRODINGER EQUATION FOR SOME TIME DEPENDENT INTERACTIONS. Note No. 314. Pietronero, L.; Salusti, E. (Rome Univ. (Italy). Istituto di Fisica). 22 Apr 1971. 6p. Dep. NTIS (U. S. Sales Only).

Some simple cases of time-dependent Hamiltonians and their elementary solutions are described. (M.O.W.)

59208 EQUATION OF MOTION FOR THE P REPRESENTATION. Crosignani, B. (California Inst. of Tech., Pasadena); Ganiel, U.; Solimeno, S.; Di Porto, P. Phys. Rev., A; 4: No. 4, 1570-4(Oct 1971).

A new equation of motion, which describes the time evolution of the P representation in the Schroedinger picture, is derived. The equation applies to a very general class of Hamiltonians, and thus should be useful in many problems. As a demonstration of the usefulness of this equation, some known results are recovered by its direct application. (auth)

59209 METHODS AND PROBLEMS OF THEORETICAL PHYSICS. IN HONOUR OF R. E. PEIERLS. Conference Held at Birmingham, England, June 1967. Bowcock, J. E. (ed.). New York; American Elsevier Publishing Company, Inc. (1970). 450p. $21.75. (CONF-670675).

Eighteen of the twenty-five papers were considered in scope for NSA; four are abstracted separately and fourteen are listed by title. (W.D.M.)

59210 MOTION OF CHARGED PARTICLES IN APPROXIMATELY ORTHOGONAL ELECTRIC AND MAGNETIC FIELDS. Kuz'min, A. F. (Special Design Bureau of Analytical Instrument Design, Leningrad). Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 599-602(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 765-9(Apr 1971).

The motion of charged particles in homogeneous electric and magnetic fields intersecting at an angle close to 90° is discussed for arbitrary orientation of the initial particle velocity. The parametric equations of the particle trajectory are obtained as a particular case of the particle trajectory in randomly intersecting electric and magnetic fields. Analytic expressions are derived for determining the particle coordinates at any instant of time as a function of the specific charge and initial velocity of the particle and the magnitude and angle of intersection of the fields. Approximate expressions are obtained which define the breakdown of the dividing and focusing properties of the fields for strictly mutual orthogonality. The fields most frequently used in a number of technical devices (multipliers, mass spectrometers, electronic instruments) are discussed. (auth)

59211 MODULATED RELATIVISTIC ELECTRON BEAMS. Korsunskii, A. M.; Repalov, N. S. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 648-50(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 826-9(Apr 1971).

The development of oscillations is examined for a modulated slightly relativistic beam. The form and position of the resonance region are found. A variable modulation period is needed for full development of the instability. (auth)

59212 GENERALIZED WIDEROEE CONDITION AND ENERGY OF A PARTICLE IN AN AXIALLY SYMMETRIC TIME-VARYING MAGNETIC FIELD. Glikman, L. G. Sov. Phys.-Tech. Phys. (Engl. Transl.); 16: No. 4, 666-8(Oct 1971).

Translated from Zh. Tekh. Fiz.; 41: No. 4, 843-7(Apr 1971).

It is shown that at certain times there is a simple connection be-

XUM

tween the magnetic flux through a circle with its center on the axis of symmetry and radius equal to the distance of the particle from this axis and the component of the magnetic field at the position of the particle parallel to the axis of symmetry. The energy of the particle at these times is estimated. The integral of the motion is found for certain time-varying fields. This quantity is then used to find the dimensions of the region occupied by the particle at any time, as well as the particle energy. (auth)

59213 EFFICIENT MONTE CARLO EVENT GENERATION METHOD FOR MULTIPERIPHERAL MODELS. **Friedman, Jerome H.; Lynch, Gerald R.; Risk, Clifford G.; Zang, Thomas A. Jr. (Univ. of California, Berkeley). J. Comput. Phys.; 8: No. 1, 144-52(Aug 1971).**

A Monte Carlo event generation method is presented that integrates multiperipheral models with good efficiency for all energies and all multiplicities up to 18. (auth)

59214 PROJECTIVE SOLUTION OF INTEGRAL EQUATIONS ARISING IN ELECTRIC AND MAGNETIC FIELD PROBLEMS. **Silvester, P.; Hsieh, M. S. (McGill Univ., Montreal). J. Comput. Phys.; 8: No. 1, 73-82(Aug 1971).**

Many integral equations arising in electric and magnetic field problems have Green's function kernels that cause difficulty in integration because of their essential singularities. By performing a simple coordinate rotation, these singularities can be shifted entirely onto one coordinate axis, so that iterated weighted numerical quadratures may be applied to evaluate exactly the projective representation of such integral operators on suitable finite-dimensional function spaces. Standard projective methods may therefore be applied to solve such integral equations accurately with very little computational effort. (auth)

59215 DERIVATION OF HYDRODYNAMICS FROM THE BOLTZMANN TRANSPORT EQUATION FOR QUASI-PARTICLES IN LIQUID ^{3}He AND FOR A PHONON GAS. **Tobenfeld, Emile Saul. Ithaca, N. Y.; Cornell Univ. (1971). 77p. University Microfilms Order No. 71-18,914.**

Thesis.

The problem of the derivation of hydrodynamics from the Boltzmann transport equation is considered for the case of quasi particles in liquid He^3 and for phonons in a solid at low temperature. It is shown that the use of the Chapman–Enskog method of developing hydrodynamics from the Boltzmann transport equation is justified for quasi particles in liquid He^3. The Navier–Stokes and Burnett equations are developed by this method. The coefficients are expressed in terms of certain integrals of the scattering cross section for single collisions. It is shown that the Chapman–Enskog method cannot be rigorously justified for the phonon gas. Conditions under which the Chapman–Enskog method would be expected to give a good approximation are developed. Numerical calculation is performed to determine whether these conditions hold for a simple model of the phonon gas. The Navier–Stokes and Burnett equations are developed in terms of the inverse collision operator for the phonon gas. Numerical calculations to determine whether the conditions for Chapman–Enskog theory hold and to calculate the coefficients of Navier–Stokes and Burnett equations are described, and progress on these calculations is reported. (Diss. Abstr. Int., B)

59216 SOLUTION OF PARTIAL DIFFERENTIAL EQUATIONS USING A SYMBOLIC STYLE OF ALGOL. **Roberts, K. V. (Culham Lab., Abingdon, Eng.); Boris, J. P. J. Comput. Phys.; 8: No. 1, 83-105(Aug 1971).**

A large class of physical problems reduces to the solution of nonlinear sets of partial differential equations. The success of mathematical physics in such problems depends closely on the available mathematical notation, which is both elegant and precise. Even so, certain information can only be obtained from numerical computations using finite-difference methods on discrete spatial and temporal grids. Existing computers are already powerful enough to handle many interesting problems in two and three dimensions, and the main limiting factor is now the time taken to develop the necessary programs. A symbolic style of writing Algol is developed using three-dimensional magnetohydrodynamics as an example. Programs written in this way are clear and concise and can be written and modified quickly with little chance for error; they can also be converted easily for use with any computer system. Thus the development of a working computational physics program need not take man-years of high-level scientific effort. The symbolic style of programming developed here overcomes the usual objections to large Fortran programs by introducing an operator formalism which is very close to the formalism developed for mathematical physics. One defines a set of difference operators which "look" and "feel" just like their differential counterparts and thus the details of the finite-difference scheme can be largely hidden from view. Although the Symbolic Algol "prototype" codes developed in this way execute too slowly for full three-dimensional production runs, the inner loops can readily be converted, either automatically or by hand, into highly optimized versions in any chosen language. (auth)

59217 UNIQUENESS OF THE POSITION OBSERVABLE IN AN IRREDUCIBLE UNITARY REPRESENTATION UP TO A FACTOR OF THE GALILEI GROUP. **Neumann, Holger (Univ., Marburg, Ger.). Ann. Phys. (Leipzig); 26: No. 2, 190-2(1971). (In German).**

An elementary quantum-mechanical system with nonvanishing mass is characterized by a continuous irreducible unitary representation up to a factor of the Galilei group in Hilbert space. An argument is given concerning the continuous irreducible unitary representations of the universal covering group of the Euclidean group such that the position observable is uniquely determined by the transformation properties under the representation of the Galilei group. (auth)

59218 RESOLUTION OF THE HIERARCHY OF GREEN'S FUNCTIONS FOR FERMIONS. **Fujita, Shigeji (State Univ. of New York, Buffalo). Phys. Rev., A; 4: No. 3, 1114-22(Sep 1971).**

The rigorous evolution equations for the one-body Green's functions ($g^>$, $g^<$) describing a system of interacting fermions are not closed (an analog of the Bogolyubov–Born–Green–Kirkwood–Yvon hierarchy for many-body distribution functions). The analysis of these equations is made in terms of proper connected diagrams. It is established that in the bulk limit, N (particle number) → ∞, Ω (volume) → ∞ while N/Ω remains finite, these equations can rigorously be transformed into closed equations with respect to ($g^>$, $g^<$). (auth)

59219 SUPPRESSION OF CHERENKOV RADIATION. **Prastein, S. Matthew (Argonne National Lab., Ill. Illinois Inst. of Tech., Chicago). Acta Phys. Austr.; 32: No. 1, 1-10(1970).**

The Fourier transform criterion for suppression of radiation is applied to the phenomenological treatment of Cherenkov radiation. It is shown that a large class of radiationless distributions may be described in terms of band-limited functions. (auth)

59220 NEW DERIVATION OF THE SECOND VIRIAL COEFFICIENT. **Servadio, Sergio (State Univ. of New York, Stony Brook). Phys. Rev., A; 4: No. 3, 1256-60(Sep 1971).**

A new, completely rigorous way of proving the relation between the second virial coefficient and the S matrix is presented. The method involves the use of the $U_{2,\infty}$ function introduced by Lee and Yang and proceeds in the most straightforward manner. Although difficulties are encountered for virial coefficients of higher order, there is hope that this type of approach might shed some light on the question of the connection between the virial series and the scattering matrix. (auth)

59221 SELF-INTERACTION AND ELECTROMAGNETIC RADIATION. **Goetz, Allan Charles. Washington, D. C.; George Washington Univ. (1971). 116p. University Microfilms Order No. 71-19,617.**

Thesis.

The present finite theories of electromagnetism are reviewed and their difficulties discussed. A new finite field theory of electromagnetism is proposed and is shown to produce results that agree with experiment. A self-interaction is found necessary to account for the incoherent radiation. The self-interaction chosen requires no renormalization and has the form originally suggested by Dirac. The structure of the Maxwell fields is analyzed using generalized function theory. The results are used to derive the synchrotron-radiation spectra for incoherent radiation and also to derive a new expression for the coherent-radiation spectra. These spectra are an accurate test of any theory of electromagnetism. Following the spirit of the classical theory, a semiclassical quantum theory of radiation is developed and the level shift of the 2s level of hydrogen is calculated without the need for renormalization. The electron is shown to contribute 429 MHz to this shift while the self-energy of the proton may well contribute the remaining 626 MHz. (Diss. Abstr. Int., B.)

59222 COMPLETE SETS OF DIAGONAL OPERATORS IN QUANTUM-STATISTICAL MECHANICS. **Caspers, W. J. (Technische Hogeschool Twente, Enschede, Netherlands); Van de Braak, H. P.; Verbeek, P. W.; Verstelle, J. C. Physica; 53: No. 2, 210-24(28 May 1971).**

Complete sets of diagonal operators, i.e., operators commuting with the Hamiltonian of a physical system, are constructed. In terms of these sets all diagonal operators can be written as a series, the uniform convergence of which is studied for infinitely large systems. This uniform convergence is introduced as a possible criterion for ergodicity. (auth)

59223 STATISTICAL MECHANICS OF AN ELECTRON GAS IN A MAGNETIC FIELD. Tsai, J. T. (State Univ. of New York, Buffalo); Wadati, M.; Isihara, A. Phys. Rev., A; 4: No. 3, 1219-38(Sep 1971).

The statistical mechanics of an interacting electron gas in a magnetic field is developed, based on a propagator method for weak fields and low temperatures. Detailed analytical considerations are given of the eigenvalues of relevant propagators, through which the grand partition function and the correlation energy are evaluated. The energy and the susceptibility are expressed in powers of r_s and the magnetic field. Corrections to the Landau susceptibility are obtained taking the finiteness of the density into consideration. In the absence of the magnetic field, the correlation energy reduces to the correct limit. The paramagnetic susceptibility and the polarization energy agree with what Brueckner and Sawada obtained by a different method in which a polarization parameter is assumed. An explicit expression for this parameter is also given. Thus, the evaluation of the correlation energy by Gell-Mann and Brueckner and that of the susceptibility by Brueckner and Sawada, Pines, and others are generalized. (auth)

59224 TRANSPORT EQUATIONS FOR DILUTE GASES WITH INTERNAL DEGREES OF FREEDOM. II. THE GENERALIZED MASTER EQUATION APPROACH. Tip, A. (FOM-Instituut voor Atoom- en Molecuulfysica, Amsterdam). Physica; 53: No. 2, 183-92(28 May 1971).

A transport equation for dilute gases with internal degrees of freedom, derived earlier from the BBGKY hierarchy, is obtained from the generalized master equation. It is demonstrated that the Zwanzig projection operator, used previously by various authors to derive the Waldmann–Snider equation, is not applicable in case generalizations of this equation are required. A different projection operator, which can be used under more general conditions, is discussed. (auth)

59225 NONLINEAR SCATTERING OF PARTIALLY COHERENT RADIATION BY FREE ELECTRONS. Chandra, Naresh; Goyal, Reva; Prakash, Hari (Univ. of Allahabad, India). J. Phys. Soc. Jap.; 31: No. 2, 326-30(Aug 1971).

The cross section for second-harmonic generation in Compton scattering is obtained, both quantum-mechanically and classically, for a radiation field of general nature in terms of fourth-order coherence functions. Strong dependence of this cross section on the nature of the incident radiation is shown by studying the special cases of coherent and chaotic beams of radiation having various polarizations and some cases of beams of radiation having stabilized amplitude. It is shown that the results reported in literature for this phenomenon hold only for coherent radiation and that those reported for unpolarized radiation are not correct. It is also shown that fourth-order coherence functions can be determined from the measurements of the intensity of the second-harmonic-scattered radiation in different directions, and the coherent states of radiation can be distinguished from the generalized coherent states. (auth)

59226 RADIATION OF SCALAR PARTICLES IN FIELD OF TWO TRAVELING ELECTROMAGNETIC WAVES MOVING TOWARD EACH OTHER. Bagrov, V. G.; Khalilov, V. R. (Moscow State Univ.). Izv. Vyssh. Ucheb. Zaved., Fiz.; No. 1, 69-73(1969). (In Russian).

The radiation of a charged spinless particle in the field of two plane electromagnetic waves traveling toward each other, and possessing linear polarization, is considered in the approximation of small field potentials. Expressions for the radiation probabilties are obtained, and the polarization properties of the radiation are studied. (tr-auth)

59227 FORMAL EQUIVALENCE OF THE HYDROGEN ATOM AND HARMONIC OSCILLATOR AND FACTORIZATION OF THE BETHE–SALPETER EQUATIONS. Basu, Debabrata (Univ. of Delhi). J. Math. Phys. (N. Y.); 12: No. 8, 1474-82(Aug 1971).

The possible factorizations of the confluent hypergeometric equation are investigated and it is shown that this leads to a formal equivalence of the usual hydrogen–atom problem with that of a set of multidimensional harmonic oscillators of appropriate classical frequency in a space of varying (even) dimensionality ranging from $4l + 4$ to 2. This method is next used to investigate the solutions of some relativistic bound-state equations. As specific examples Goldstein's eigenvalue problem and the Wick–Cutkosky scalar meson equation are considered. A formal similarity also exists between the Goldstein problem and the scalar meson equation in the zero binding limit. The factorization of either of these equations leads to an infinite ladder of non-square integrable solutions. On the other hand, for arbitrary non-vanishing binding energies a complete solution of the scalar meson problem was obtained by investigating the zero-energy factorization of the equation. (auth)

59228 SCATTERING OF LIGHT BY A FLOW OF ELECTRONS THROUGH A CRYSTAL. Baryshevskii, V. G. (Belorussian State Univ., Minsk). Dokl. Akad. Nauk BSSR; 15: No. 4, 306-8(Apr 1971). (In Russian).

The scattering of photons of a laser wave by an electron beam as it passes through a crystal is investigated. If the wave length of the scattered photons is comparable to the interatomic distances, such photons undergo diffraction. This leads to a splitting of the frequencies of the scattered quanta, and, as a consequence of the effect of anomalous transmissions, to a decrease of the absorption of the photons in the medium. This anomalous transmission in the x-ray portion of the spectrum will occur in the bremsstrahlung radiation of charged particles passing through the crystal. (tr-auth)

59229 BRANDOW BOSON LINKED-CLUSTER EXPANSION APPLIED TO THE HIGH-DENSITY CHARGED BOSON GAS. Lee, J. C. (Northwestern State Univ., Natchitoches, La.). Phys. Rev., A; 4: No. 5, 2050-4(Nov 1971).

The Brandow boson linked-cluster expansion was used to redo the Foldy calculation of the Bogolyubov theory for a charged boson gas. The particle-number conservation is treated exactly. The ring diagrams were summed using the same techniques as used by Gell-Mann and Brueckner for the electron gas. The next-most-divergent diagrams (twisted rings) were also summed. These diagrams contain a renormalized hole line and thus show explicitly the dynamics of the condensate which is treated only in an average way in the Bogolyubov theory. The results for the ground-state energy and the condensation fraction agree exactly with Foldy in the high-density limit. (auth)

59230 EXACT RESULTS FOR A QUANTUM MANY-BODY PROBLEM IN ONE DIMENSION. Sutherland, Bill (Univ. of California, Berkeley). Phys. Rev., A; 4: No. 5, 2019-21(Nov 1971).

A system of either fermions or bosons interacting in one dimension is investigated by a two-body potential $V(r) = g/r^2$ with periodic boundary conditions. In addition to rederiving known results for correlation functions and thermodynamics in the thermodynamic limit, expressions are presented for the one-particle density matrix at zero temperature and particular (nontrivial) values of the coupling constant g, as a determinant of order $N \times N$. These concise expressions allow a discussion of the momentum distribution in the thermodynamic limit. In particular, for a case of repulsive bosons, the determinant is evaluated explicitly, exhibiting a weak (logarithmic) singularity at zero momentum, and vanishing outside of a "Fermi" surface. (auth)

59231 NUMERICAL ESTIMATE OF TRAJECTORIES OF CHARGED PARTICLES IN MAGNETIC AND VARIABLE-IN-TIME ELECTRIC FIELDS WITH DISCRETE POTENTIAL DISTRIBUTION. Grigorishin, I. L.; Belonuchkina, I. I. (Lab. of Electronics, Minsk). Vestsi Akad. Navuk BSSR, Ser. Fiz.-Tekh. Navuk; No. 1, 75-83(1969). (In Russian).

Such a distribution was obtained by computation of equations for the Dirichlet problem by the method of networks and by using grid electron integrators. On this basis, suggestions are made concerning the invariance of components of field strength in the elemental squares of network differences that permit integration of the equations of motion in each square. The cases of purely electric fields, crossed and combined, possessing the axial field symmetry, are examined. The influence of space charge is neglected. (tr-auth)

59232 COMPOSITE PARTICLES IN MANY-BODY SYSTEMS. Sakakura, Arthur Y. (Colorado School of Mines, Golden). Phys. Rev. Lett.; 27: No. 12, 822-6(20 Sep 1971).

Presented herein is a second-quantized formulation for a system of interacting nuclei and electrons expressed in terms of the creation and annihilation operators of various species of atoms and ions which can be formed by combining various numbers of the "elementary" particles. Processes such as ionization and recombination appear naturally. Explicit expressions for interatomic forces including exchange effects are generated from a "cluster expansion" reminiscent of the Ursell expansion. (auth)

59233 SINGULARITY STRUCTURE OF THE PERTURBATION SERIES FOR THE GROUND-STATE ENERGY OF A MANY-FER-

XUM

MION SYSTEM. Baker, George A. Jr. (Brookhaven National Lab., Upton, N. Y.). Rev. Mod. Phys.; 43: No. 4, 479-531(Oct 1971).

Calculational procedures are developed for the ground-state energy of a many-fermion system. The entire theory is developed from the many-body Schroedinger equation via perturbation theory. The linked cluster expansion is derived by elementary methods. The analytic singularities of the energy function are analyzed, and procedures designed to avoid or overcome them. Results for the calculation of the energy in the presence of a purely repulsive two-body force are reviewed, and the situation is found to be reasonably satisfactory, though good results are restricted to wea potentials when the system is not dilute. Results for an attract potential surrounding a strongly repulsive core are reviewed, procedures described for calculations in this case. A sample c culation with an assessment of the probable errors is reviewed (auth)

59234 PHASE SPACE AND QUANTUM THEORY. Brittin, Wesley E. (Univ. of Colorado, Boulder). pp 47-91 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

The problem of quantum mechanical representations in phase space is reviewed from a unified point of view. Particular attention is given to the use of localized states in phase space and their use in the representation theory. Their relation to coherent states is discussed as is their use in many-body theory. (W.D.M.)

59235 GROUP THEORY FOR PERMUTATION DEGENERACY IN FOUR ELECTRONS AND THE PAULI EXCLUSION PRINCIPLE. Van Vleck, J. H. (Harvard Univ., Cambridge, Mass.). pp 341-7 of Topics in Modern Physics. /Brittin, Wesley E. (ed.). Boulder, Colo.; Colorado Associated Univ. Press (1971).

The four-electron problem is treated as an explicit and instructive example, which is illuminating not just because it shows the restrictive role of the exclusion principle but also because it furnishes simple illustrations of many basic concepts of group theory such as homomorphy, isomorphy, etc., particularly as used to obtain representations and their characters. It is emphasized that the treatment is purely didactic, and does not pretend to give any basically new results. (W.D.M.)

59236 MARKOV APPROACH TO DENSITY FLUCTUATIONS DUE TO TRANSPORT AND SCATTERING. I. MATHEMATICAL FORMALISM. van Vliet, K. M. (Univ. of Montreal). J. Math. Phys. (N. Y.); 12: No. 9, 1981-98(Sep 1971).

A kinetic approach to fluctuations and correlations of stochastic processes depending on a continuous set of parameters y is presented. In particular, particle densities $n^p(y,t)$ which may refer to macroscopic densities in position space, or to microscopic quantities such as distributions in phase space, or occupancies of quantum states of which the labeling is continuous (as with Bloch states in solids) are considered. In a Markovian sense such processes are infinite dimensional. The fluctuating particle densities are considered in a Hilbert space: the analog of de Groot's a-space for nonspatial-dependent variables. Mainly, a Langevin description is used, i.e., one starts from presumed phenomenological equations, amended with source densities $\xi^p(y,t)$. A theorem is derived for the density–density or two-point covariance function (Λ theorem). In its general form, the theorem applies to the nonequilibrium steady state. It closely resembles the generalized g–r theorem for finite-dimensional processes. However, the solutions may involve extra parts stemming from stochastic boundary conditions and constraints. Simplifications for the thermal equilibrium case and the connection with generalized Onsager's relations are discussed. A variety of expressions for the spectral intensities $\Sigma^{pq}(y,y',\omega)$ are derived. In order to justify the Langevin procedure as well as to calculate the source terms and generalized Fokker–Planck moments, one considers the master-rate functional $W_{\gamma\gamma'}$ for transitions $\gamma \to \gamma'$ of the over-all state. Expressions are given for transitions involving change of species and scattering due to one- or two-body collisions. These determine uniquely the quantities entering into the Λ theorem. The statistical-mechanical basis for the formalism is discussed in some detail. (auth)

59237 MARKOV APPROACH TO DENSITY FLUCTUATIONS DUE TO TRANSPORT AND SCATTERING. II. APPLICATIONS. van Vliet, K. M. (Univ. of Montreal). J. Math. Phys. (N. Y.); 12: No. 9, 1998-2012(Sep 1971).

Applications of a macroscopic and microscopic nature are given of the Markov formalism, developed in the previous paper, for finding the pair-correlation function, two-point covariance function, and spectral intensities from the phenomenological transport equations, transitions, and scattering. As macroscopic examples, Rayleigh diffusion, Coulomb correlations, and space-charge-limited flow in solids are discussed. The diffusion equation is shown to be not strictly Markovian, though correct Langevin diffusion sources are easily found. Dielectric relaxation is shown to be a macroscopic manifestation of Coulomb correlations in a plasma. The Λ theorem of the previous paper yields for the pair-correlation functions the original Debye–Hückel result plus a δ term. The spectra for space-charge-limited flow due to single-carrier injection are treated with the Green's-function procedure. The discrepancies between existing theories are removed since the Coulomb correlations in the steady state are shown to be not of the Debye–Hückel type. As microscopic applications, we consider ideal gases in the presence of streaming due to fields, an extension of Lax's work. The connection with the BBGK two-point equations for one- and two-body collisions is established. Finally, one integrates over the stochastic Boltzmann equation to obtain stochastic hydrodynamic equations. These provide a microscopic basis for the noise sources associated with electrical conduction, heat conduction, and with the Navier–Stokes equation. Results for the hot-electron Boltzmann gas are compared with those of Price. (auth)

59238 ENSEMBLE VERSUS TIME AVERAGE PROBABILITIES IN RELATIVISTIC STATISTICAL MECHANICS. Landsberg, P. T.; Johns, K. A. (University Coll., Cardiff, Wales). Pure Appl. Chem.; 22: No. 3-4, 487-92(1970).

From International conference on thermodynamics; Cardiff, Wales (1 Apr 1970).

Reasons are advanced why discrete probabilities are not Lorentz-invariant. Such probabilities can be obtained as time average probabilities Π_i for state i in frame I. They can also be obtained from an ensemble E_1 of systems which, like the system of interest, are each on average at rest in a certain frame I_0. Such probabilities Q_i transform like the Π_i and ergodicity is then a Lorentz-invariant notion; If the ensemble is of the usual type (ensemble E_0) whose systems are all at rest in I_0, then the ensemble-based probabilities are Lorentz-invariant. If E_0 is used ergodicity is not a Lorentz-invariant notion; If entropy is regarded as invariant and entropy maximization is used, the canonical equilibrium probabilities Π_i which one finds contain an extra term which is not usually found. (auth) (UK)

59239 THEORY OF THE UNRESTRICTED HARTREE–FOCK EQUATION AND ITS SOLUTIONS. I. Fukutome, Hideo (Kyoto Univ.). Progr. Theor. Phys. (Kyoto); 45: No. 5, 1382-1406(May 1971).

A general theory of the unrestricted Hartree–Fock equation and its solutions is developed. Two different but, of course, equivalent nonconventional formulations of the Hartree–Fock equation are presented. The first formulation is derived from the equation of the density matrix. It is shown that the Hartree–Fock equation is equivalent to an intersection problem of certain quadratic hypersurfaces. The second formulation is derived from a parametric representation of the density matrix and the orbitals. The Hartree–Fock equation is converted to a coupled nonlinear equation for the parameter matrices. This form of the Hartree–Fock equation may be transformed into the form analogous to the Bogolyubov equation of superconductivity. Various representations of the Hartree–Fock energy are derived. A close correlation between the Hartree–Fock energy and the gaps of the orbital energies is indicated. An estimation for the upper and lower bounds of the number of different solutions of the Hartree–Fock equation is obtained. They are respectively $2^{(N^2-K)}$ and 2^K, where N is the dimension of the Hilbert space of the orbitals and K is the smaller number of n and N-n, n being the number of electrons in the system. PHYSICS (HIGH ENERGY)

Particle Interactions and Properties (Experimental)

59240 SEARCH FOR FRACTIONAL CHARGE USING LOW TEMPERATURE TECHNIQUES. Hebard, Arthur Foster. Stanford, Calif.; Stanford Univ. (1971). 150p. University Microfilms Order No. 71-19,698.

Thesis.

The purpose of the experiment described is to search for fractionally charged particles called quarks. The symmetries of high-energy physics would be greatly simplified if quarks with charge $\pm\frac{1}{3}$ and $\pm\frac{2}{3}$ the charge of an electron exist as the basic building blocks of all the known mesons and baryons. The proton, for example, would be made from two $+\frac{2}{3}$ quarks and one $-\frac{1}{3}$ quark. The central assumption of the experiment is that cosmic rays have been bombarding the earth since time began with sufficient energy to create free quarks which will combine with matter to form long-lived fractionally charged entities. A low-temperature apparatus is described which is capable of detecting electric charge smaller than that of an electron on a superconducting niobium sphere with a mass of 7×10^{-5} gm. A quark on the niobium sphere would be observable as an irreducible fractional charge and the probability of finding one is proportional to the mass of the sphere. For comparison, the mass of the niobium sphere is more than 10^6 times the mass of a typical Millikan oil drop. The sphere is suspended in a stable magnetic field between two parallel capacitor plates with an oscillation period of 1.5 seconds and a Q in the range of 1500-3000. A square-wave electric field is applied at the resonant frequency and the amplitude change, as recorded by a SQUID magnetometer, is a direct measure of the electric charge on the sphere. Separate positron (Na-22) and electron (Tl-204) radioactive sources are used for charge control. Preliminary results obtained for a single sphere indicate a nonzero residual charge of magnitude -0.37 ± 0.03. This value of approximate magnitude $-\frac{1}{3}$ does not necessarily imply the reality of quarks because of the fact that there might exist spurious charge forces which are caused by the apparatus. Such a force might arise for example if the induced electric dipole moment on the sphere, which is proportional to the electric field, interacts with a fixed field gradient, caused by a surface dipole layer on the capacitor plates, to give a force linear in the electric field and hence indistinguishable from the charge force. Before this result can be taken as evidence for a quark, the sensitivity of this apparent residual charge to different experimental conditions will be investigated and the results checked by measurements on other spheres which must have charge intercepts of only $-\frac{1}{3}$, $+\frac{1}{3}$ and zero. (Diss. Abstr.)

59241 (CONF-710915-2) REVIEW OF EXPERIMENTS ON NUCLEON-NUCLEON BREMSSTRAHLUNG. Halbert, M. L. (Oak Ridge National Lab., Tenn.). [1971]. 24p. Dep. NTIS.

From Symposium on the two-body force in nuclei; Ann Arbor, Mich. (7 Sep 1971).

The review of nucleon–nucleon bremsstrahlung experiments includes proton–proton and neutron–proton bremsstrahlung. (J.F.P.)

59242 INELASTIC ELECTRON SCATTERING AT LARGE ANGLES. Miller, Guthrie. Stanford, Calif.; Stanford Univ. (1971). 147p. University Microfilms Order No. 71-19,727.

Thesis.

Electron-proton scattering cross sections were measured at electron scattering angles of 18, 26, and 34° for incident electron energies up to 18 GeV. These data extend in four momentum transfer squared (q^2) from 1 to 20 GeV^2 and in missing mass squared (W^2) up to 25 GeV^2. Using previously reported data at 6 and 10°, a separation of the two inelastic form factors was made in the deep inelastic region ($W^2 > 4$ GeV^2) for q^2 from 1.5 to 8 GeV^2. The transverse form factor is found to dominate in agreement with the expectations of various "parton" theories (for spin $\frac{1}{2}$ partons). Determination of the inelastic form factor W_2 allowed an investigation of the question of "scaling," i.e., that $\nu W_2 = F(\nu/q^2)$ in the deep inelastic large q^2 region. (Diss. Abstr.)

59243 PHOTOPRODUCTION OF π^0's FROM NEUTRONS AT 4 GeV. Bolon, G. C.; Bellenger, D.; Lobar, W.; (and others) (Massachusetts Inst. of Tech., Cambridge). Contract AT(30-1)-2098. Phys. Rev. Lett.; 27: No. 14, 964-6(4 Oct 1971).

The reaction $\gamma + n \rightarrow \pi^0 + n$ was measured at a photon energy of 4 GeV for $0.2 \leq -t \leq 1.8$ (GeV/c)^2. The cross section is slightly less than that with protons as a target. (auth)

59244 HEAVY LIQUID BUBBLE CHAMBER ANALYSIS OF η^0 NEUTRAL DECAY MODES: $\eta^0 \rightarrow 3\pi^0$ AND $\eta^0 \rightarrow \gamma\gamma$. Baglin, C. (Ecole Polytechnique, Paris); Bezaguet, A.; Degrange, B.; (and others). Nucl. Phys.; B22: No. 1, 66-84(1970).

The following decays of η^0 mesons produced in 350,000 photographs of a heavy liquid bubble chamber were observed: $\eta^0 \rightarrow \pi^+\pi^-\pi^0$, $\eta^0 \rightarrow 3\pi^0 \rightarrow 6\gamma$, $\eta^0 \rightarrow \gamma\gamma$. All the γ-rays coming from these decays were observed and measured; this provides a direct separation of the two neutral modes and independent measurements of the two following branching ratios: $R_1 = \Gamma(\eta^0 \rightarrow 3\pi^0)/\Gamma(\eta^0 \rightarrow \pi^+\pi^-\pi^0)$ and $R_2 = \Gamma(\eta^0 \rightarrow \gamma\gamma)/\Gamma(\eta^0 \rightarrow \pi^+\pi^-\pi^0)$. This analysis was done with 526 $\eta^0 \rightarrow \pi^+\pi^-\pi^0(\pi^0 \rightarrow \gamma\gamma)$, 199 $\eta^0 \rightarrow 3\pi^0 \rightarrow 6\gamma$ and 401 $\eta^0 \rightarrow \gamma\gamma$ events. The result $R_1 = 1.50^{+0.15}_{-0.29}$ is in agreement with the theoretical predictions assuming that $\eta^0 \rightarrow 3\pi$ decays are pure $\Delta I = 1$ transitions. The result $R_2 = 1.72 \pm 0.25$, combined with R_1 and compared with the present world average of the ratio $\Gamma(\eta^0 \rightarrow$ neutrals$)/\Gamma(\eta^0 \rightarrow \pi^+\pi^-\pi^0)$, is compatible with the absence of the mode $\eta^0 \rightarrow \pi^0\gamma\gamma$ or with only a small decay rate for this last mode. The $\eta^0 \rightarrow 3\pi^0$ Dalitz plot was studied, the three π^0 being reconstructed from the measurements of the 6γ-rays, using kinematical fits. No significant variation of the $\eta^0 \rightarrow 3\pi^0$ amplitude was found. The coefficient of the term quadratic in pion energies in this amplitude is found to be $\alpha = -0.32 \pm 0.37$. (auth)

59245 CALCULATED COSMIC-RAY MUON SPECTRA AT HIGH ENERGIES (>20 GeV). O'Brien, Keran (Atomic Energy Commission, New York). Phys. Rev., D; 4: No. 3, 635-8(1 Aug 1971).

Calculations of sea-level cosmic-ray muon spectra were made at 75°, 80°, 85°, and 88.75° between 20 and 1000 GeV, and compared with measurements made at Argonne National Laboratory. Although the experimental results are a consistent 60% of the calculated values, leading to too few muons being found at high zenith angles, it is felt that this does not support the Utah anomaly, as the discrepancy is energy- and angle-independent. Similarly, no exotic processes, such as the failure of special relativity, seem to be operating. (auth)

59246 ELECTROMAGNETIC INTERACTIONS OF HIGH-ENERGY COSMIC-RAY MUONS. Allkofer, O. C.; Grupen, C.; Stamm, W. (Univ., Kiel). Phys. Rev., D; 4: No. 3, 638-46 (1 Aug 1971).

The electromagnetic interactions of cosmic-ray muons in the energy range up to 1 TeV were investigated with a spark-chamber calorimeter in combination with the Kiel spectrograph. The purpose was to investigate the different kinds of electromagnetic processes (knock-on, direct-pair, bremsstrahlung, and multiple pion production) in the range of energy transfer from 0.2 to 100 GeV. The production of pions is in reasonable agreement with the theoretical prediction of Daiyasu et al. In the region of high energy transfer (>2 GeV) with experimental results agree with Bhabha's theory of the knock-on process as well as with Murota's theory of direct pair production. However, in the region of energy transfer around 1 GeV there are minor deviations from these theories, in contradiction with accelerator data. (auth)

59247 PHENOMENOLOGY OF MUON SHOWERS UNDERGROUND. Davis, K. H.; Fall, S. M.; Ingebretsen, R. B.; Stenerson, R. O. (Univ. of Utah, Salt Lake City). Phys. Rev., D; 4: No. 3, 607-26(1 Aug 1971).

Measurements of shower arrival directions (incident in a range of zenith angles between 40° and 70° and slant depth of rock between 2×10^5 and 6.5×10^5 g cm^{-2}), structure, and intensities are used as the basis to develop a detailed descriptive phenomenology of muon showers underground. Distributions in right ascension and declination corresponding to minimum values of the median primary energy ranging from 25 TeV for single detected muons to 9000 TeV for events where six muons were detected revealed no compelling evidence for anisotropy in the primary radiation. Measurements of counting rates of groups of two and three of the nearly parallel muons in individual showers as a function of muon separation (structure) were found to be consistent with a shower radial density distribution having the form $\rho(r) = P(r/\sigma) \times \exp(-r/\sigma)$, where r is the distance of the shower axis in m, P is a polynomial in (r/σ), $\sigma = K \times (\sec\theta)^{1.3}/E_\mu^{0.8}$, θ is the zenith angle in degrees, E_μ is the threshold muon energy in units of TeV, and $K = 3.6$ m. The empirical shower radial density distribution above reduces to one predicted by Adcock, Wdowczyk, and Wolfendale on the basis of a detailed shower development calculation with a value of $K = 4$

XUM

m at an energy of 1 TeV and a zenith angle of 45°. Assuming that the distribution of shower sizes is proportional to a power law in shower size, the exponent of the shower-size distribution was measured and found to lie in the range −3.5 to −4.5. The parameters of an empirical density spectrum were optimized by iterative fits to the numbers of events where one to three muons were detected with the result that best-fit parameters were close to those previously obtained by Porter and Stenerson using a smaller sample of shower data. The predicted energy and angular dependence is shown to be in reasonable qualitative agreement with intensities measured in 20-m^2 detectors. (auth)

59248 CHARGED π-MESON PHOTOPRODUCTION ON NUCLEI AT $E_0 = 560$ MeV. Grishaev, I. A.; Krinitsyn, A. N.; Lapin, N. I.; (and others) (Physical-Technical Inst., Kazan). Yadern. Fiz.; 14: No. 1, 35-9(Jul 1971). (In Russian).

Yields of charged pions on C, Al, Cu, and Pb nuclei are measured at the maximal energy of the bremsstrahlung γ quanta $E_0 = 560$ MeV. The measurements are performed on the electron linear accelerator at the Physico-Technical Institute of the Ukranian Academy of Sciences. The π^+ and π^- mesons with kinetic energies 40 and 65 MeV were registered using photoemulsions under 60 and 120° angles. The dependence of the total yield on the atomic weight is given. The experimental data are discussed in framework of the optical model. (auth)

59249 COMPLEX INVESTIGATION OF EXTENSIVE AIR-SHOWER CORE WITH ENERGY $\geq 10^{15}$ eV. Cherdyntsev, K. V.; Rakobol'skaya, I. V.; Nikol'skii, S. I.; Varkovitskaya, A. Ya. (Lebedev Inst. of Physics, Moscow). Yadern. Fiz.; 14: No. 2, 371-7(Aug 1971). (In Russian).

An event of penetration of an extensive air-shower core with energy $\geq 10^{15}$ eV through the Tien Shan complex plant is discussed. A conclusion is presented on the multi-core character of the shower that is due to large transversal momenta. A change of inelastic interaction process with high energy transfer to the electron−photon component is noted. (auth)

59250 HIGH-ENERGY ELECTRON−POSITRON ELASTIC SCATTERING. Bartoli, B. (CNEN, Frascati, Italy); Felicetti, F.; Ogren, H.; (and others). Phys. Lett.; 36B: No. 6, 593-7 (18 Oct 1971).

The analysis of 5164 wide angle Bhabha events collected at several c.m. energies between 1.4 and 2.4 GeV using the Frascati e^+-e^- storage ring, ADONE, is presented. The results are in agreement with the predictions of quantum electrodynamics within the experimental errors (±10%). (auth)

59251 MULTIPARTICLE PRODUCTION FROM e^+e^- INTERACTIONS AT HIGH ENERGY. Bartoli, B. (CNEN, Frascati, Italy); Felicetti, F.; Ogren, H.; (and others). Phys. Lett.; 36B: No. 6, 598-602(18 Oct 1971).

Measurements of multiple particle production at ADONE, the Frascati e^+e^- storage ring, were carried out at c.m. energies 1.4 GeV to 2.4 GeV. The hadronic nature of the observed particles is discussed and a lower limit of 30 nbarn set for the total multiparticle cross section. (auth)

59252 DETERMINATION OF THE REAL PART OF THE ρ-NUCLEON FORWARD SCATTERING AMPLITUDE AND THE RELATIVE $\rho-\omega$ PRODUCTION PHASE. Biggs, P. J.; Braben, D. W.; Clifft, R. W.; Gabathuler, E.; Rand, R. E. (Daresbury Nuclear Physics Lab., Warrington, Eng.). Phys. Rev. Lett.; 27: No. 17, 1157-60(25 Oct 1971).

The real part of the ρ−nucleon forward scattering amplitude was obtained by a measurement of the photoproduction of asymmetric electron−positron pairs from a carbon target. A determination of the relative $\rho-\omega$ production phase is also made. At a mean incident photon energy of 4 GeV the ratio of the real to the imaginary part of the ρ−nucleon amplitude is found to be -0.28 ± 0.12. (auth)

59253 STUDY OF THE VERTICES $\pi^0\gamma\gamma$, $\eta\gamma\gamma$, AND $\eta'\gamma\gamma$ WITH ALMOST REAL PHOTONS. Parisi, J. (Univ., Paris); Kessler, P. Lett. Nuovo Cim.; No. 15, 755-9(9 Oct 1971).

It is suggested that the vertices $\pi^0\gamma\gamma$, $\eta\gamma\gamma$, and $\eta'\gamma\gamma$ can be studied experimentally from processes of the type $e^-e^+ \to e^-e^+X \to e^-e^+\gamma\gamma$ ($X = \pi^0$, η, or η'). The outgoing electron and positron are detected at very small angles with respect to their incident directions, in coincidence with the two photons produced at large angles with respect to the beam axis. It is shown that the cross sections predicted are high enough to ensure reasonably large counting rates with future electron-positron storage rings of energy ~1 to 3 GeV and luminosity $\sim 10^{32}$ cm^{-2} s^{-1}. (L.B.S.)

59254 (BNL-tr-449) SEARCH FOR THE DECAY $\mu^+ \to e^+ + e^+ + e^-$. Korenchenko, S. M.; Kostin, B. F.; Nekrasov, G. K.; Mitsel'makher, G. V.; Smirnov, V. S. (Joint Inst. for Nuclear Research, Dubna (USSR)). Translated by S. J. Amoretty (Brookhaven National Lab., Upton, N. Y.), from report JINR-P1-5542. 4p. Dep. NTIS.

A cylindrical spark chamber was used to search for the decay $\mu^+ \to e^+ + e^+ + e^-$. It was established that the upper limit for the branching ratio for this decay is $6.2(10)^{-2}$, which is about 20 times less than that determined earlier. (J.F.P.)

59255 (BNL-tr-451) SEARCH FOR THE $\pi^+ \to e^+ + \nu_e + e^+ + e^-$ DECAY. Korenchenko, S. M.; Kostin, B. F.; Mitsel'makher, G. V.; Nekrasov, K. G.; Smirnov, V. S. (Joint Inst. for Nuclear Research, Dubna (USSR)). Translated by S. J. Amoretty (Brookhaven National Lab., Upton, N. Y.), from report JINR-P1-5250. 5p. Dep. NTIS.

A spark chamber was used to search for the decay $\pi^+ \to e^+ + \nu + e^+ + e^-$. An upper limit for the branching ratio of this decay was found. (J.F.P.)

59256 BRANCHING RATIO $K \to e\nu/K \to \mu\nu$: A TEST OF V−A THEORY OF WEAK INTERACTIONS. McReynolds, John Frederick. Berkeley, Calif.; Univ. of California (1970). 91p. University Microfilms Order No. 71-20,854.

Thesis.

An optical spark chamber experiment utilizing an axially focusing cylindrically symmetric spectrometer has gathered 62.6 ± 11 $K \to e\nu$ events, giving a branching ratio Ke_2 $K\mu_2 = 2.32 \pm 0.39 \times 10^{-5}$, and setting new limits of $0 \leq |(f_P/f_A)| < 1.75 \times 10^{-4}$ or $1.82 \times 10^{-3} < |(f_P/f_A)| < 2.12 \times 10^{-3}$. A beam of 500 K^+/pulse with $K^+/\pi^+ = 0.002$ from the Bevatron external proton beam was stopped on the spectrometer axis. Charged particles over 0.4 or 4π were allowed a single orbit in the spectrometer. Such particles in a 12% momentum bite passed through a 300-psi ethane Cherenkov counter, a scintillator and spark chamber array designed for ±1% momentum analysis, and into a lead cylinder, spark chamber, and scintillator array designed for muon rejection. Events were scanned and measured on SASS, an automatic scanning system. A total of 150,000 events were measured, analyzed, and kinematically reconstructed. These events satisfied trigger requirements for Ke_2, for K → charged particle + γ, and for normalization to $K\mu_2$, $K\pi_2$, and Ke_3. (Diss. Abstr.)

59257 MASS OF MUON NEUTRINOS. Gabos, Zoltan; Demsoreanu, Brutus. Stud. Univ. Babes-Bolyai, Ser. Phys.; 16: No. 1, 21-4(1971). (In German).

The possibility of determining the mass of the muonic neutrino from measurement of the longitudinal polarization of the muon in $\pi^- \to \mu^- + \bar{\nu}_\mu$ decay is examined. (L.B.S.)

59258 EXPERIMENTAL STUDY OF THE DALITZ PLOT IN THE DECAY $K_L^0 \to \pi^+ + \pi^- + \pi^0$. Takats, Martha Carroll. Philadelphia; Univ. of Pennsylvania (1970). 132p. University Microfilms Order No. 71-19,290.

Thesis.

In a study of 6270 $K_L^0 \to \pi^+ + \pi^- + \pi^0$ decays, the Dalitz coordinates $X = 3(T_+-T_-)/Q$ and $Y = (3T_0-Q)/Q$ were measured, in an attempt to test the $\Delta I = 1/2$ rule and CP-conversion in the decay. The experiment was performed in the 49° neutral beam at the Princeton-Pennsylvania Accelerator. The tracks of the charged pions were recorded by means of wire spark chambers and their momenta determined by means of a large-aperture magnet with field of about 4000 gauss. Time-of-flight measurements were used to separate out leptonic decays and to resolve the kinematic ambiguity in the reconstruction of kaon momentum. In previous experiments, reconstruction of the quantity $P_0'^2$, the kaon momentum in the frame in which the momentum of the charged-pion pair is purely transverse, has permitted fairly good separation of leptonic and $K \to 3\pi$ decays, by the requirement that $P_0'^2$ be positive. The usual cut on $P_0'^2$ was not used, but many events with $P_0'^2 < 0$ could not be reconstructed on the Dalitz plot. A Monte-Carlo calculation was performed to correct the data for detection efficiencies and extract the spectrum on the Dalitz plot, and to check the detection efficiency for leptonic decays. On the basis of the calculations, it was estimated that the leptonic background is less than 5%, and that the reconstructed leptonic decays populate the Dalitz plot uniformly. The spectrum was extracted in two ways: by binning events in X and Y, and by transforming the Dalitz plot to the unit circle and using the method of orthogonal functions. The results for fitting the data to a quadratic spectrum $F(X,Y) = 1 + aY + bY^2 + cX^2 + dX$ were identical in the two methods. If $\Delta I = 1/2$, these coefficients may be simply related to the coefficients for τ^+ and $\tau^{+\prime}$ decays. The coefficient a = -0.563 ± 0.026, when compared to the results for τ^+ decay, is consistent with the $\Delta I = 1/2$ rule, but large quadratic coefficients were found which appear to violate $\Delta I = 1/2$. The fit to a quadratic spectrum was very poor ($P < 0.0001$). Certain bins were found to be sensitive to differences between Monte-Carlo calculations and data with respect to the number of events with $P_0'^2 < 0$. When these bins were omitted, a much better fit was obtained ($P \sim 0.1$). In the new fit, a = -0.771 ± 0.040, in violation of $\Delta I = 1/2$. The slope σ_0, which is proportional to the coefficient a, has been measured in four previous experiments, with a total of about 10,000 events. Two of the reported values are consistent with $\Delta I = 1/2$; two are not. The results differ by more than five standard deviations. It is believed that sensitivity to the $P_0'^2$ cut has resulted in the disagreement among the quoted slopes. The coefficient d measures the interference term between I = 1 and CP-violating I = 2 states. It is found that d = 0.011 ± 0.032 is consistent with CP conservation in the decay. (Diss. Abstr.)

59259 SEARCH FOR THE DECAY OF THE SHORT-LIVED NEUTRAL K MESON INTO TWO CHARGED PI MESONS AND ONE NEUTRAL PI MESON. **Jones IV, Lewis Hammond.** Urbana, Ill.; Univ. of Illinois (1971). 148p. University Microfilms Order No. 71-21,148.

Thesis.

A spark chamber experiment was run at Argonne National Laboratory to search for the decay $K_S^0 \to \pi^+\pi^-\pi^0$. CP does not forbid this decay, but the CP-conserving states are strongly suppressed by centrifugal barriers. Therefore, observation of a large amplitude for $K_S^0 \to \pi^+\pi^-\pi^0$ would indicate probably CP violation in this decay mode. The method used was to measure the time distribution of $K^0 \to \pi^+\pi^-\pi^0$ decays in the region from 0.5 to 6.5 K_S^0 lifetimes. The K^0 mesons were produced in a 3 cm long carbon target via the reaction $\pi^-p \to K^0\Lambda$ at a beam momentum of 3 GeV/c. Identification of the Λ insured that there was no $\overline{K}^0$ contamination in the data at t = 0. The momenta of the charged decay products were measured using thin foil spark chambers placed in a 10 kG magnetic field. Photons from π^0 decay were identified by observation of showers in heavy plate spark chambers. Two charged particle tracks and one photon track, consistent with $K_{\pi 3}^0$ decay, were required. The time distribution for the 99 events in the final sample was fit by the method of maximum likelihood for the complex amplitude ratio $x + iy = [(K_S^0 \to \pi^+\pi^-\pi^-)/(K_L^0 \to \pi^+\pi^-\pi^0)]$. The result is $x = -0.09 \pm 0.19$, $y = 0.56 \pm 0.43$. This result indicates a possible violation of CP in $K_{\pi 3}^0$ decays but is also consistent with CP conservation at the one-standard deviation level. The value of χ^2 for x = y = 0 is 6.10 for four degrees of freedom with χ^2 probability = 19.2%. A second result found in the likelihood fit is statistically preferred over the first result but is ruled out on theoretical and experimental grounds. (Diss. Abstr.)

59260 PRECISION MEASUREMENT OF THE LIFETIME AND DECAY BRANCHING RATIO OF THE Λ^0 HYPERON. Baltay, C. (Columbia Univ., New York. Brookhaven National Lab., Upton, N. Y.); Bridgewater, A.; Copper, W. A.; Habibi, M.; Yeh, N. Phys. Rev., D; 4: No. 3, 670-6(1 Aug 1971).

A precision measurement of the Λ^0 lifetime τ_Λ and the branching ratio $R = (\Lambda \to p\pi^-)/(\Lambda \to \text{all})$ was carried out. The results are $\tau_\Lambda = (2.54 \pm 0.04) \times 10^{-10}$ sec and $R = 0.646 \pm 0.008$. The errors include both the statistical errors and our estimate of the systematic errors. (auth)

59261 STRANGENESS-CHANGING LEPTONIC DECAY RATES FROM THE $\Sigma^\pm$ HYPERONS. Cole, J. (State Univ. of New York, Stony Brook); Lee-Franzini, J.; Loveless, R. J.; (and others). Phys. Rev., D; 4: No. 3, 631-5(1 Aug 1971).

The strangeness-changing leptonic branching ratios of the $\Sigma^\pm$ hyperon were determined from a stopping K^- exposure in the BNL-Columbia 30-in. hydrogen bubble chamber. The ratio $(\Sigma^- \to ne\nu)/(\text{all } \Sigma^- \text{ decays})$ is $(0.97 \pm 0.15) \times 10^{-3}$, and the ratio $(\Sigma^- \to n\mu\nu)/(\text{all } \Sigma^- \text{ decays})$ is $(0.38 \pm 0.11) \times 10^{-3}$. No evidence is found for $\Delta S = \Delta Q$ violations, and an upper limit for the ratio of decay rates $[(\Sigma^+ \to ne\nu)/(\Sigma^- \to ne\nu)]$ is determined to be <12.6% with 95% confidence. (auth)

59262 MEASUREMENT OF K_{e4}^+-DECAY RATES AND TEST OF THE $\Delta S = \Delta Q$ RULE. Bourquin, M. (Univ., Geneva); Boymond, J. P.; Extermann, P.; (and others). Phys. Lett.; 36B: No. 6, 615-18(18 Oct 1971).

In a study of 1609 K_{e4} decays observed at the CERN PS, the rate of $K^+ \to \pi^+\pi^-e^+\nu$ was found to be $(3.32 \pm 0.31) \times 10^3$ sec^{-1}. An upper limit of 43 sec^{-1} at the 95% confidence level was obtained for the $\Delta S = \Delta Q$ violating mode $K^+ \to \pi^+\pi^+e^-\overline{\nu}$. (auth)

59263 DETERMINATION OF THE LOW-ENERGY $\pi-\pi$ PHASE SHIFTS AND FORM FACTORS IN K_{e4}^+ DECAY. Basile, P. (CEN, Saclay, France); Brehin, S.; Diamant-Berger, A.; (and others). Phys. Lett.; 36B: No. 6, 619-22(18 Oct 1971).

In a study of 1609 K_{e4}^+ decays observed at the CERN PS a single solution for the form factors and the $\pi-\pi$ phase-shift difference $\Delta = \delta_s^0 - \delta_p^1$ averaged over the invariant dipion mass ($m_{\pi\pi} = 313$ MeV) was calculated. $\Delta = 0.37 \pm 0.07$ was found. (auth)

59264 MEASUREMENT OF THE $K_L^0 \to 2\gamma$ BRANCHING RATIO AND SEARCH FOR $K_S^0 \to 2\gamma$ DECAYS. Repellin, J.-P. (Laboratoire de l'Accelerateur Lineaire, Orsay, France); Wolff, B.; Chollet, J. C.; (and others). Phys. Lett.; 36B: No. 6, 603-6 (18 Oct 1971).

Using an optical spark chamber set-up, the two photon decay rate of neutral K mesons behind a regenerator was measured. $K_L^0 \to 2\gamma$ decays are normalized to $K_S^0 \to 2\pi^0$ events, so the result depends on the K^0 regeneration in copper at 2 GeV/c and has a value of $\Gamma(K_L^0 \to 2\gamma)/\Gamma(K_L^0 \to \text{all}) = (5.0 \pm 1.0) \times 10^{-4}\ [22\text{ mb}/(|f - \overline{f}|/k)]^2$. $K_S^0 \to 2\gamma$ events are not observed, and from the normalization to $K_S^0 \to 2\gamma^0$, $\Gamma(K_S^0 \to 2\gamma)/\Gamma(K_S^0 \to \text{all}) < 1.2 \times 10^{-3}$ was obtained with 90% confidence. (auth)

59265 (JINR-P2-5991) INTRANUCLEAR CASCADES IN LIGHT NUCLEI. Abdinov, O. B.; Barashenkov, V. S. (Joint Inst. for Nuclear Research, Dubna (USSR). Lab. of Theoretical Physics). 1971. 13p. (In Russian). Dep. NTIS (U. S. Sales Only).

A model of intranuclear cascades, allowing for a density change in the target nucleus proportional to the cascade development, is applied to light hydrogen-type nuclei. In the energy range $T \leq 1$ GeV the effect of the density change affects the properties of the cascading particles comparatively weakly (the number of low-energy particles decreasing somewhat), but substantially influences the yield of various isotopes at energies $T \cong 300$ to 400 MeV. The calculation of cluster structure of target nuclei noticeably affects the yield of isotopes. (tr-auth)

59266 (SJC-P-71-1) ANTIPROTON-PROTON CHARGE EXCHANGE AND ELASTIC SCATTERING AT 232 MeV. Hirose, T.; Yamagata, Fukawa, M.; (and others) (Tokyo Univ. (Japan). Inst. for Nuclear Study). Apr 1971. 14p. Dep. NTIS (U. S. Sales Only).

Angular distributions of charge exchange scattering ($\bar{p}p \to \bar{n}n$) and elastic scattering ($\bar{p}p \to \bar{p}p$) were measured at energy of 232 MeV. Pictures used were obtained by exposure with an 80-cm Saclay chamber. In order to identify the reaction $\bar{p}p \to \bar{n}n$, emitted $\bar{n}$s were observed inside the fiducial volume as characteristic annihilation stars with odd number of prongs and positive net charge. For $\bar{p}p \to \bar{n}n$, 42018 pictures were scanned twice for 3.5 and 7 prong stars associating with 0 prongs, and 282 events were obtained. Number of events of $\bar{p}p \to \bar{p}p$ obtained by scan of 1540 pictures was 664. Measurement was performed with a film plane digitizer (Vanguard) for the $\bar{p}p \to \bar{n}n$ and with an image plane digitizer (D-MAC) for the $\bar{p}p \to \bar{p}p$, least counts of which were 2.5 μm and 5.0 μm, respectively. Peaks of the distribution of total residuals were at around 4 μm in both measurements. For analysis of the $\bar{p}p \to \bar{n}n$, each event was weighted by detection probability of annihilation stars of $\bar{n}$. Cross sections of the $\bar{p}p \to \bar{n}n$ and $\bar{p}p \to \bar{p}p$ were (9.9 ± 1.1) mb and (53.5 ± 3.0) mb respectively. The angular distributions were given as a function of four momentum transfer squared t and center of mass angle θ^*. Dependence of the cross section on t was represented by a diffraction model; $(d\sigma/dt = AJ_1^2[(a + t/\hbar)\sqrt{|t|}]/t$, $A = b + ct$. The angular distributions at 232 MeV were well reproduced with parameters a = 1.04 fm, b = 29.4 mb, and c = 49.5 mb$\cdot$fm^{-1}, and with t = 0.60 fm. (auth)

59267 DI-PION PRODUCTION AND TWO-BODY ANNIHILATIONS IN ANTIPROTON-PROTON INTERACTIONS AT 7 GeV/c. **Mandzy, John.** Nashville; Vanderbilt Univ. (1971). 147p. University Microfilms Order No. 71-20,297.

Thesis.

The final states $\bar{p}p\pi^+\pi^-$, $\bar{p}p\bar{p}p$, K^+K^-, and $\pi^+\pi^-$ were analyzed in antiproton-proton interactions at a beam momentum of 7 GeV/c. None of the events processed successfully fit the final state $\bar{p}p\bar{p}p$. At the 95% confidence level, this corresponds to an upper limit on the cross section for this final state of 5 μb. In scanning for event candidates for the final states K^+K^- and $\pi^+\pi^-$, scanning cuts were employed in order to remove some of the background. This experiment is therefore only sensitive to K^+K^- and $\pi^+\pi^-$ final states whose four-momentum transfer (between the incoming positively charged particle and the outgoing positively charged particle) lies in a certain region. For the K^+K^- final state this region was: $t_{min} = 0.36 \leq t_p/K^+ \leq 0.73$ and $11.8 \leq t_p/K^+ \leq 12.5 = t_{max}$. For the $\pi^+\pi^-$ final state this region was: $t_p/\pi^+ = 0.58 \leq t_{p/\pi^+} \leq 0.92$ and $12.0 \leq t_{p/\pi^+} \leq 13.6 = t_{max}$. None of the events processed success-

XUM

fully fit either of these two final states. At the 95% confidence level, this corresponds to an upper limit on the cross section for each of the final states of 5 μb. The total cross section for the final state $\bar{p}p\pi^+\pi^-$ was found to be (2.38 ± 0.13) mb. This channel is dominated by production of the N*(1236) in both the $\bar{N}^{*--}$ states and N^{*++} states. The observed mass and width for both the $\bar{N}^{*--}$ and N^{*++} were (1225 ± 7) MeV and (110 ± 15) MeV, respectively. An attempt was made to understand N*(1236) production as the incoherent sum of three processes: single isobar production, double isobar production, and nonisobar processes. The relative amount of each of these processes is, respectively: somewhat greater than 42%, between 34% and 45%, and on the order of 13% to 23%. The data indicate that the N*(1236) production mechanism is highly peripheral. The Treiman–Yang angular distribution of the isobar decays is flat as expected for pion exchange. The distribution of the Jackson angle is less peaked than expected for simple pion exchange and it also shows a significant forward-backward asymmetry. This asymmetry suggests background interference in addition to the usual absorptive processes. The data were compared with the predictions of a particular one-pion-exchange model, the "double scattering" model. There was good agreement between mass plots predicted by the model and the data in the kinematic region in which the comparison was made. There is good evidence for two signals in the $N\pi\pi$ mass spectrum. Their masses are (1460 ± 12) MeV and (1712 ± 12) MeV, and their widths are estimated to be (61 ± 35) MeV and (112 ± 43 MeV), respectively. Neither of these enhancements is a kinematic reflection of the production of an isobar with the remaining baryon as each of these signals is considerably enhanced when such events are deleted. The dominant decay mode of the 1712 MeV signal appears to be via an uncorrelated $N\pi\pi$ state. There is also good evidence for the ρ_0 meson, having a mass of (765 ± 25) MeV and an estimated width of (75 ± 21) MeV. The estimated cross sections for these three signals are 1460 MeV – (60 ± 24) b, 1712 MeV – (136 ± 45) μb, ρ_0 – (52^{+32}_{-16}) μb. (Diss. Abstr.)

59268 ISOSPIN INVARIANCE IN THE REACTION $np \to \pi^0 d$. Wilson, S. S. (Univ. of Michigan, Ann Arbor); Longo, M. J.; Young, K. K.; Helland, J. A.; Schrock, B. L. Nucl. Phys.; B33: No. 1, 253-80(1971).

A measurement of the differential cross section for the reaction $np \to \pi^0 d$ was made at the Lawrence Radiation Laboratory 184-inch cyclotron. A neutron beam with kinetic energies up to 720 MeV was incident on a liquid hydrogen target. The angle and momentum of the deuterons were measured using an analyzing magnet and wire spark chambers with a magnetostrictive readout. Deuterons were separated from protons by time-of-flight. The photons from the decaying π^0 were not detected. The neutron energy was calculated from the measured deuteron angle and momentum. Out of 5×10^5 events recorded, 1.1×10^5 events were the desired $\pi^0 d$ reaction. The cross sections were compared to those for the reaction $\pi^+ d \to pp$ as a test of isotopic spin invariance in strong interactions. The symmetry of the cross sections about 90° was also investigated, and an upper limit of about 1% was placed on the real part of the ratio of isospin-violating to isospin-conserving amplitudes. (auth)

59269 COMPARISON OF HIGH-ENERGY HADRON–DEUTERON SCATTERING DATA WITH THE GLAUBER MODEL. Bradamante, F.; Conetti, S.; Fidecaro, G.; (and others). Nucl. Phys.; B33: No. 1, 165-72(1971).

The results of a series of experiments on $\pi^- d$ and pd elastic scattering in the 10 GeV region are compared with the prediction of the Glauber multiple scattering model. A disagreement is found in the double scattering region, which does not seem to be explainable in terms of the uncertainty in our current knowledge of the individual hadron-nucleon differential cross section. A way of restoring agreement could be that of reducing the usually quoted amount of screening between the two nucleons in the deuteron. (auth)

59270 POLARIZATION AND DIFFERENTIAL CROSS SECTION FOR THE REACTION $pp \to \pi^+ d$ AT 425 MeV. Dolnick, Carl L. (Univ. of Chicago). Nucl. Phys.; B22: No. 2, 461-77(1970).

Differential cross sections and polarizations for the reaction $pp \to \pi^+ d$ were measured at an incident polarized proton energy of 425 MeV (lab) over the range of meson angles 10 to 90 deg in the c.m. system. The final-state pion and deuteron were detected in coincidence in two sets of scintillation counter arrays and the data were analyzed by an on-line computer. Evidence is found for the presence of d-wave mesons. The value 1.30 ± 0.06 mb is obtained for the total cross section. (auth)

59271 ANNIHILATION PROCESS $p\bar{p} \to 2\pi^+ 2\pi^-$ AT 2.5 GeV/c. Clayton, J. (Univ. of Liverpool); Mason, P.; Muirhead, H.; (and others). Nucl. Phys.; B22: No. 1, 85-92(1970).

Abundant resonance production was observed in this reaction, the channels $\rho^0\pi^+\pi^-$, $f\pi^+\pi^-$ accounting for 51 ± 3% and 39 ± 3% respectively of all $2\pi^+ 2\pi^-$ annihilations. No evidence of the A_2 meson was found. Data on the possible existence of the two-pion decay model of the S*(1070) are given. The Reggeised multiperipheral model of Chan, Łoskiewicz and Allison was applied to the reaction, and reasonable agreement between predictions and experimental data found. (auth)

59272 STUDY OF $\bar{p}p$ ANNIHILATION AT 2.5 GeV/c WITH PRODUCTION OF TWO KAONS IN FINAL STATE. Badier, J. (Ecole Polytechnique, Paris); Bonnet, A.; Drevillon, B.; (and others). Nucl. Phys.; B22: No. 2, 512-24(1970).

Cross sections for final states and resonance production are given and compared to a statistical model proposed by Lamb. Transverse and longitudinal momenta are studied and the Goldhaber effect is tested. Baryon exchange mechanisms appear. (auth)

59273 pp AND pd ELASTIC SCATTERING AT 50 AND 70 GeV. Devenski, P. A.; Zayachki, V. I.; Zlatanov, Z. M.; (and others) (Joint Inst. for Nuclear Research, Dubna, USSR). Yadern. Fiz.; 14: No. 2, 367-70(Aug 1971). (In Russian).

The experiment is performed at the Serpukhov accelerator. The differential cross sections of the pp elastic scattering at 50 GeV and of the pd elastic scattering at 70 GeV are determined using the method of recoil particle registration by the nuclear emulsion. The region of the 4-momentum transfers $0.01 < |t| < 0.17\ (\mathrm{GeV}/c)^2$ was studied. The slope parameters were determined. The following results have been obtained: $b_{pp} = 11.06 \pm 0.28\ (\mathrm{GeV}/c)^{-2}$ and $b_{pd} = 40.7 \pm 0.7\ (\mathrm{GeV}/c)^{-2}$. (auth)

59274 NONRELATIVISTIC PARTICLES PRODUCED IN INTERACTIONS OF MULTICHARGED COSMIC RAY NUCLEI WITH LIGHT NUCLEI OF EMULSION. Dudkin, V. E.; Potapov, Yu. V.; Khokhlova, Z. S.; Shimanskaya, N. S.; Yakovlev, R. M. Yadern. Fiz.; 14: No. 2, 378-81(Aug 1971). (In Russian).

The results are presented of studying grey and black tracks in 82 events of multicharged cosmic ray nuclei ($E \geq 700$ MeV/nucleon) interaction with light nuclei of the emulsion. The energy distribution of the double-charged particles produced in such interactions is much more hard than that in the nucleon–nuclear collisions. The mean energy of the double-charged particles in the nuclear–nuclear ($Z \geq 3$) interactions is three as high as in the case of high-energy proton collisions with light nuclei. (auth)

59275 EXPERIMENTAL COMPARISON OF $\bar{d}p$ AND $\bar{p}d$ TOTAL CROSS SECTIONS. Gorin, Yu. P.; Denisov, S. P.; Donskov, S. B.; (and others) (Inst. of High-Energy Physics, Serpukhov, USSR). Yadern. Fiz.; 14: No. 1, 134-6(Jul 1971). (In Russian).

Antideuteron–proton (at the momentum of 13.3 GeV/c) and antiproton–deuteron (p = 6.65 GeV/c) total interaction cross sections are measured in order to test the CPT invariance. The experiments are carried out by means of the transmission counters in conditions of good geometry. The ratio of the $\bar{d}p$ and $\bar{p}d$ total cross sections is found to be 1.002 ± 0.024. The $\bar{d}d$ and $\bar{p}p$ total cross sections are also measured. The obtained data enable one to determine the total cross sections of interactions of antineutrons with protons, neutrons, and deuterons. (auth)

59276 STUDY OF THE REACTION $\bar{p}d \to p_s\pi^+2\pi^-\pi^0$ AT 5.5 GeV/c INCIDENT MOMENTUM. Braun, H.; Evrard, D.; Fridman, A.; (and others) (Centre de Recherches Nucleaires, Strasbourg). Z. Phys.; 247: No. 2, 107-116(1971).

A study of a 150,000-picture exposure of $\bar{p}d$ at 5.5 GeV/c yielded 152 events satisfying the hypothesis $\bar{p}d \to p_s\pi^+2\pi^-\pi^0$. For the events with proton spectator in the momentum range 100 to 280 MeV/c one obtained the cross section of 0.11 ± 0.02 mb. Assuming the validity of the impulse approximation a cross section of 0.43 ± 0.06 mb is estimated for the reaction $\bar{p}n \to \pi^+2\pi^-\pi^0$. The rate for single p meson production and an upper limit for double p production are given. A modified multiperipheral Regge model was used in order to describe the general features of the data. (auth)

59277 ANGULAR DISTRIBUTION OF SECONDARY PARTICLES PRODUCED IN THE INTERSECTING STORAGE RINGS AT AN ENERGY EQUIVALENT TO 1500 GeV. Phys. Lett.; 36B: No. 6, 611-14(18 Oct 1971).

The angular distribution of secondary relativistic charged particles was measured in the ISR by means of nuclear emulsions used as detectors. The result confirms the cosmic-ray observations of a dip in the angular distribution around 90° in the centre-of-mass system of the colliding protons. (auth)

59278 ENERGY SPECTRUM OF ^{8}Li FRAGMENTS RESULTING FROM BOMBARDMENT OF AgBr BY 28 GeV PROTONS. Kane, G. (Manhattan Coll., New York); O'Friel, Z. Lett. Nuovo Cim.; 2: No. 15, 799-804(9 Oct 1971).

Ilford G-5 emulsions 600 μ thick were exposed to 28-GeV protons. 1272 "hammer tracks," characteristic of lithium-8 were located. The measured lengths of the tracks were converted to energies by means of range–energy tables. (L.B.S.)

59279 SPIN PARITY STUDIES OF THE ETA PI DECAY OF THE A2 MESON AND INVESTIGATION OF THE A2 PRODUCTION MECHANISM IN THE REACTION PI-MINUS PROTON GOES TO A2-MINUS PROTON. Lacy, Jeffrey Linn. Urbana, Ill.; Univ. of Illinois (1971). 113p. University Microfilms Order No. 71-21,164.

Thesis.

The results of a spin-parity analysis of the $\eta\pi^-$ decay mode of the A_2^- meson produced in the reaction $\pi^- p \rightarrow A_2^- p$ are presented. Data for the analysis are drawn from bubble chamber experiments between 3.9 and 16 GeV/c. The analysis favors $J^P = 2^+$ for both the upper and lower regions of the A_2. Possible evidence for a weakly produced $J^P = 1^-$ daughter state is also presented. The evidence comes largely from an interference effect observed in the lower A_2 region. Using the $A_2^- \rightarrow \eta\pi^-$ data along with data on the decay channel $A_2^- \rightarrow \rho^0\pi^-$ at 5.0, 7.5, and 11.2 GeV/c, the production mechanism of the A_2^- in the reaction $\pi^- p \rightarrow A_2^- p$ is investigated. Assuming that this reaction is dominated by a t channel exchange mechanism the isospin and J parity of the exchange are investigated. The s and t cross section dependence of the data is compared with a simple Regge model. (Diss. Abstr.)

59280 STUDY OF Λ AND Σ^0 FINAL STATES PRODUCED BY THE INTERACTION OF K^- MESONS ON DEUTERIUM AT 4.5 GeV/c. Ammann, Arthur Carl. Lafayette, Ind.; Purdue Univ. (1971). 154p. University Microfilms Order No. 71-20,419.

Thesis.

The study of four-body final states produced by the interaction of 4.48-GeV/c K^- mesons on neutrons is made. The data result from a 370,000-picture exposure taken of the deuterium filled Mura thirty inch bubble chamber at the Argonne Zero Gradient Synchrotron. Reactions studied include $K^- n \rightarrow \Lambda\pi^+\pi^-\pi^-$ (1), $K^- n \rightarrow \Sigma^0\pi^+\pi^-\pi^-$, $\Sigma^0 \rightarrow \Lambda\gamma$ (2), $K^- n \rightarrow \Lambda\pi^+\pi^-\pi^-\pi^0$ (3), $K^- n \rightarrow \Lambda\pi^+\pi^-\pi^-$mm (4), and $K^- n \rightarrow \Lambda\pi^- K^+ K^-$ (5), where all Λ particles decayed to a visible vee. Unusual detail is presented regarding the separation of reactions (1) and (2). This is done primarily to facilitate the study of the recently reported Σ (1640) seen in reaction (1). Production mechanism and branching ratios are investigated. The charged three-pion spectrum shows a significant signal in the A_2 region. The high mass and dominant 3π decay mode of this object are compared with results from pion-nucleon interactions. Angular distributions show no inconsistency with a 2^+ spin parity assignment. Vector mesons are studied primarily in conjunction with simultaneous Σ^- (1385) production. These quasi-two body reactions are seen to proceed peripherally probably by a combination of strange meson exchange. Spin-density matrix elements show marginal agreement with the previous quark model predictions. (Diss. Abstr.)

59281 $K^- p$ CHARGE EXCHANGE AND ELASTIC SCATTERING NEAR 1670 MeV. Golson, James Philip. Durham, N. C.; Duke Univ. (1970). 105p. University Microfilms Order No. 71-21,539.

Thesis.

The reactions $K^- p \rightarrow \bar{K}^0 n$ and $K^- p \rightarrow K^- p$ were studied at center of mass energies near 1670 MeV with data from a 500,000 picture exposure at the Brookhaven National Laboratory Alternating Gradient Synchrotron using the BNL thirty-inch, liquid-hydrogen bubble chamber. Approximately 1100 events consistent with the $K^- p \rightarrow \bar{K}^0 n$ hypothesis and 5100 events consistent with the $K^- p \rightarrow K^- p$ hypothesis were identified. Differential cross sections for the two reactions were obtained. The differential cross sections were expanded in terms of Legendre polynomials as $(d\sigma/d\Omega) = \lambda\!\!\!^-{}^2 \Sigma_m A_m P_m (\cos\theta)$ where $\lambda\!\!\!^-$ is the center of mass wavelength of the incident particle, the A_m is the energy-dependent coefficient, and the $P_m (\cos\theta)$ is the Legendre polynomial. The A_m obtained in this experiment for both reactions agreed well with those presented from other experiments. Additional structure in the narrow-energy region covered in this experiment is suggested by the data. (Diss. Abstr.)

59282 MANY BODY FINAL STATES FROM $\pi^+ d$ INTERACTIONS NEAR 3 GeV/c. Miller, William Joseph. Lafayette, Ind.; Purdue Univ. (1971). 200p. University Microfilms Order No. 71-20,508.

Thesis.

A study was made of the five- and six-charged-particle final states from the interaction of π^+ beams on a deuterium target at a laboratory beam momentum of 2.7 and 3.1 GeV/c. The data were obtained from a film exposure of the 72-inch bubble chamber at the Lawrence Radiation Laboratory at Berkeley, California. Many elementary particle resonances were observed including the η, ω, Δ^{++}, ρ, η′, D, E, f′, δ, and A_2. The masses and widths of each particle were determined, and the spin and parity of the η′, D, and E were analyzed. Data on the η′ were combined with other experiments to determine the SU-3 mixing angle for η and η′ using the Regge-pole Model. (Diss. Abstr.)

59283 STUDY OF BARYON SYSTEMS AND RELATED EFFECTS IN $K^- d$ INTERACTIONS AT 12.6 GeV/c. Antich, Pietro Paolo. Baltimore; Johns Hopkins Univ. (1971). 146p. University Microfilms Order No. 71-21,017.

Thesis.

An analysis of interactions of 12.6 GeV/c K^- mesons in deuterium is reported. This work is primarily devoted to the study of baryon systems. The nature of an enhancement centered at 1.45 GeV is investigated which is observed both in the $(p\pi^-)$ mass spectrum in the reaction $K^- d \rightarrow K^-\pi^- p p_s$ and in the distributions of the $(n\pi^+\pi^-)$ and of the $(p\pi^+\pi^-)$ masses in the reactions $K^- d \rightarrow K^-\pi^-\pi^+ n p_s$ and $K^- d \rightarrow K^-\pi^-\pi^+ p n_s$, respectively. The three reactions are analyzed with a diffraction dissociation model and the relevant cross sections are given. In a study of the production of the Ξ^- and Ω^- hyperons, it is found that the cross section for Ξ^- production is $\sigma = 40 \pm 10\ \mu b$; the cross section for Ω^- production is of the order of 2 μb. The Ξ^- hyperons are produced preferentially in the forward direction in the overall c.m. (i.e., they are aligned with the incoming K^-). From a study of the low $K^-\pi^-$ mass region in the reaction $K^- d \rightarrow K^-\pi^- p p_s$, it is found that the Kπ elastic scattering cross section in the isospin $^3\!/_2$ state is of the order of 2 mb. (Diss. Abstr.)

59284 QUASI-TWO BODY PRODUCTION INVOLVING $Y_1{}^*$ RESONANT STATES IN K^- MESON–PROTON INTERACTIONS AT 3.9, 4.6, AND 5.0 GeV/c. Jaeger, Klaus Bruno. Syracuse, N. Y.; Syracuse Univ. (1970). 309p. University Microfilms Order No. 71-21,522.

Thesis.

A bubble chamber experiment based upon 700,000 pictures of K^- mesons in hydrogen which was performed by groups from Syracuse University and Brookhaven National Laboratory is described. The Brookhaven 80″ liquid hydrogen bubble chamber was exposed to seven different runs of separated K^- beams at 3.9, 4.6, and 5.0 GeV/c. Quasi-two body cross sections were determined for the channels $K^- + p \rightarrow$ (2 charged particles) $+ \Lambda(\Sigma^0)$ and $K^- + p \rightarrow p + \pi^- + \bar{K}^0$ for the 4.6 and 5.0 GeV/c data. The observed values served as an important supplement to other experimental information in exhibiting the quasi-two body cross section behavior as a function of the incident K^- meson laboratory momentum. Production of Y_1^* resonances was studied in the channels $K^- + p \rightarrow \Lambda + \pi^+ + \pi^-$, $K^- + p \rightarrow \Sigma^0 + \pi^+ + \pi^-$; and $K^- + p \rightarrow p + \pi^- + \bar{K}^0$ at the 3.9, 4.6, and 5.0 GeV/c energies. Significant Y_1^{*+} (1915) and Y_1^{*+} (2250) production was only observed in the $\Sigma^0\pi^+\pi^-$ final state with the Y_1^{*+} (1385) and Y_1^{*+} (1670) also seen in the $\Lambda\pi^+\pi^-$ channel. The masses and widths of these resonances within the $\Sigma^0\pi^+\pi^-$ final state were determined as (1390 ± 6) MeV with $\Gamma = (33 \pm 12)$ MeV for the Y_1^{*+} (1385), (1670 ± 6) MeV with $\Gamma = (110 \pm 12)$ MeV for the Y_1^{*+} (1670), (1940 ± 11) MeV with $\Gamma = (90 \pm 20)$ MeV for the Y_1^{*+} (1915), and (2280 ± 14) MeV with $\Gamma = (100 \pm 20)$ MeV for the Y_1^{*+} (2250). Subsequent assignment of the Y^*'s to the SU(3) symmetry scheme yielded good agreement by utilizing the $\Sigma^0\pi^+$ decay rates of the Y_1^{*+} (1915) within the $J^P = {}^5\!/_2{}^+$ baryon octet and of the Y_1^{*+} (2250) within the ${}^7\!/_2{}^-$ octet. The Σπ and Λπ decay rates of the Y_1^{*+} (1385) are consistent with predicted SU(3) rates within the ${}^3\!/_2{}^+$ decuplet. Decay rates obtained in formation experiments for the Y_1^{*+} (1670) are consistent with SU(3) predictions for the ${}^3\!/_2{}^-$ baryon octet. The result of the Y_1^{*+} (1670) $\rightarrow \Sigma^0\pi^+$ rate from this experiment is much larger and subsequently inconsistent with SU(3) predictions. Hence the Y_1^{*+} (1670) decay parameters for the presented data were not employed within the context of SU(3) leaving the possible existence of more than one Y^* resonance in this final state for this mass region open for further experimental study. (Diss. Abstr.)

59285 STUDY OF INTERMEDIATE ANGLE $\pi^{+-} p$ ELASTIC SCATTERING FROM 3.0 to 5.0 GeV/c. Paik, Han Won. Bloomington, Ind.; Indiana Univ. (1971). 69p. University Microfilms Order No. 71-21, 308.

Thesis.

A study is made of a $\pi^{\pm} p$ elastic scattering experiment performed at the Argonne National Laboratory Zero-Gradient Synchrotron. Both positive and negative pions at incident momenta of 3.0, 3.5, 4.0, and 5.0 GeV/c were incident on a liquid hydrogen target, and the scattered particles were detected by arrays of scintillation counters and wire spark chambers. The geometry of the experimental layout was such as to cover an angular range

XUM

from 55 to 130° in the center of mass frame. Both π^+ and π^-p angular distributions are characterized by the presence of a nonshrinking forward diffraction peak, a dip or shoulder near $t = -0.9$ $(GeV/c)^2$ and a deep minimum near $t = -3.0$ $GeV/c)^2$, all of which were previously observed in experiments at momenta above 2.5 GeV/c. In addition the data show the presence of a shoulder for π^+p and indicate another minimum for π^-p. Both occur approximately at a constant value of $\theta_{c.m.} = 125°$. The experimental results can be described either using an optical model or in terms of a t-channel Regge exchange model. (Diss. Abstr.)

59286 OBSERVATION OF NATURAL-PARITY EXCHANGE IN ρ^0 PRODUCTION. Carroll, J. T. (Univ. of Wisconsin, Madison). Firebaugh, M. W.; Walker, W. D.; (and others). Contract AT(11-1)-881. Phys. Rev. Lett.; 27: No. 15, 1025-8(11 Oct 1971).

In a study of $\pi^-p \rightarrow \rho^0n$ and $\pi^+n \rightarrow \rho^0p$ at 7 GeV/c, a distinct change in the $\pi\pi$ angular distribution is observed for $|t_{np}| \geq 0.3$ $(GeV/c)^2$. Here there is a strong $\sin^2\theta \sin^2\varphi$ term in the decay angular distribution, which is indicative of natural-parity exchange. The observed effects are attributed to A_2 exchange. (auth)

59287 ISOSPIN INVARIANCE AND πN BACKWARD SCATTERING. Korkea-Aho, M.; Toernqvist, N. A. (Univ. of Helsinki). Nucl. Phys.; B33: No. 1, 239-52(1971).

The predictions of isospin invariance in πN backward data from threshold to 13 GeV/c are studied. Below 1.5 GeV/c especially below 1 GeV/c the present published experimental data systematically saturate and even violate the triangle inequality implied by isospin invariance. Conventional electromagnetic corrections or mass and width differences in formed resonances (as e.g., the Δ^{++} and Δ^0) are an order of magnitude too small to explain the discrepancy. Thus either there are large systematic errors in the data or isospin invariance is violated, inherently or by strongly enhanced electromagnetic effects. Above 1.5 GeV/c the inequality is satisfied by the data and the expected high-energy behavior from the Regge model of Δ and N_α dominance is discussed. Duality and exchange degeneracy predictions of phase relations between isospin amplitudes are used to speculate on the possible connection between duality and the fact that the data lie close to the limit of the inequality. (auth)

59288 PRODUCTION OF THE g-MESON IN $\pi N \rightarrow g^0N$ CHARGE EXCHANGE CHANNELS AT 7 GeV/c. Matthews, J. A. J. (Univ. of Toronto); Prentice, J. D.; Yoon, T. S.; (and others). Nucl. Phys.; B33: No. 1, 1-12(1971).

Data from π^+d and π^-p experiments at 7 GeV/c were combined to yield 10654 events in the $\pi^+\pi^-$ mass spectrum. A spin-parity analysis of this data favors a spin-parity assignment of $J^P = 3^-$ for the $g^0(1670)$ meson. Spin-parities 1^- and 5^- were not in agreement with our data. An analysis of the differential cross section for ρ^0, f^0, and g^0 production using the one-pion exchange model plus form factors was consistent with significant widths for g^0 decays to channels other than $\pi^+\pi^-$, while being in good agreement with the experimental branching ratios for ρ^0 and f^0 mesons. (auth)

59289 DEDUCTIONS FROM NEW $\pi^-p \rightarrow \pi^0n$ DATA AT LARGE MOMENTUM TRANSFERS. Barger, V. (Univ. of Wisconsin, Madison); Phillips, R. J. N. Contract AT(11-1)-881. Nucl. Phys.; B33: No. 1, 22-8(1971).

New measurements of $d\sigma/dt$ $(\pi^-p \rightarrow \pi^0n)$ at 3.67 and 4.83 GeV/c suggest that the ρ Regge trajectory continues to fall linearly out to $t = -5$ $(GeV/c)^2$. A comparison with elastic data indicates furthermore that the dips in $d\sigma/dt$ $(\pi^{\pm}p)$ near $t = -2.8$ and -4.8 $(GeV/c)^2$ are associated with zeros of the t-channel isospin-zero (vacuum exchange) contributions. Both these properties indicate that a t-channel explanation is appropriate through the range $-t < 5$ $(GeV/c)^2$. The triangular inequalities following from isospin invariance all seem to be satisfied, but imply collinearity of the $I_t = 0$ and $I_t = 1$ amplitudes near $t = -4.3$; this is a difficult condition for some models to meet. (auth)

59290 FURTHER EVIDENCE FOR THE DECAY MODE $X^0 \rightarrow \gamma\gamma$ AND DETERMINATION OF THE BRANCHING RATIO $X^0 \rightarrow \gamma\gamma/X^0 \rightarrow$ TOTAL. Basile, M.; Bollini, D.; Dalpiaz, P.; (and others) (CERN, Geneva. Istituto Nazionale di Fisica Nucleare, Bologna. Univ., Bologna. Centre National de Recherches Scientifiques, Strasbourg). Nucl. Phys.; B33: No. 1, 29-41 (1971).

41 ± 8 events of the type $X^0 \rightarrow \gamma\gamma$ were observed in a study of the reaction $\pi^-p \rightarrow n(X^0 \rightarrow \gamma\gamma)$ at 1.6 GeV/c incident π-momentum. This provides further evidence to our previous observation of this new X^0 decay mode and allows the determination of the branching ratio $\Gamma(X^0 \rightarrow \gamma\gamma)/\Gamma(X^0 \rightarrow \text{total}) = (1.7 \pm 0.4)\%$. The theoretical implications of this result are discussed. (auth)

59291 EXPERIMENTAL STUDY OF TWO-BODY AND QUASI-TWO-BODY REACTIONS IN K^-n INTERACTIONS AT 3 GeV/c. Scheuer, J. C. (CEN, Saclay, France); Barloutaud, R.; Merrill, D.; (and others). Nucl. Phys.; B33: No. 1, 61-83(1971).

All data accumulated in the study of the (quasi) two-body reactions produced in K^-n interactions at 3 GeV/c are presented. From the general features of the differential cross sections, as well as from the smallness of exotic amplitudes in the t-channel, it appears that the forward and backward scatterings should be well described even at this energy by t- and u-channel interactions. (auth)

59292 π^+p ELASTIC SCATTERING AT 3.6 GeV/c. MacNaughton, J.; Butler, W. R.; Coyne, D. G.; Hicks, G. M.; Trilling, G. H. (Univ. of California, Berkeley). Nucl. Phys.; B33: No. 1, 101-8 (1971).

The elastic scattering of 3.6 GeV/c π^+ mesons by protons was studied in a hydrogen bubble chamber experiment. The elastic cross section has a measured value of 7.07 ± 0.20 mb. The forward diffraction peak has been fitted in the region $0.05 \leq -t \leq 0.6$ $(GeV/c)^2$ by a form $(d\sigma/dt) = Ae^{Bt}$, where $A = 46.5 \pm 1.8$ mb/. $(GeV/c)^2$ and $B = 6.85 \pm 0.20$ $(GeV/c)^{-2}$. From this fit and the optical theorem, the magnitude of the ratio of real to imaginary forward amplitude is 0.39 ± 0.06, in reasonable agreement with dispersion relation calculations and simple Regge model predictions. (auth)

59293 IMPROVED PARTIAL WAVE ANALYSIS OF $\bar{K}N \rightarrow \bar{K}N$ FROM 800 TO 1200 MeV/c. Conforto, B. (Univ. of Chicago); Harmsen, D. M.; Lasinski, T.; (and others). Nucl. Phys.; B34: No. 1, 41-70(1971).

An extensive search for resonant states was performed through an energy dependent partial wave analysis of $\bar{K}N$ data in the momentum region 777–1226 MeV/c. The $K^-p \rightarrow K^-p$, $\bar{K}^0n$ differential cross sections, polarization angular distributions and total K^-p cross sections were included in the fit. In addition to the well established hyperons, evidence is reported for a resonant state $\Sigma(1760)$ of $J^P = \frac{1}{2}^-$ and for the assignment $J^P = \frac{3}{2}^+$ for a $\Lambda(1870)$ state previously assigned to $J^P = \frac{7}{2}^+$. From the $K^-p \rightarrow K^-p$ differential and total cross sections between 436 and 1226 MeV/c the ratio of the real to the imaginary part of the forward scattering amplitude has been derived as a function of K^- incident momentum. These results are found to be consistent with the predictions of several dispersion relation calculations. (auth)

59294 MEASUREMENT OF THE MAGNETIC MOMENT OF THE Λ^0 HYPERON. Barkov, L. M.; Gurevich, I. I.; Makar'ina, L. A.; (and others). JETP Lett. (USSR) (Engl. Transl.); 14: No. 2, 60-3(20 Jul 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 2, 93-7(20 Jul 1971).

Preliminary results are given on a new measurement of the magnetic moment of the Λ^0 hyperon produced in the $\pi^- + p \rightarrow \Lambda^0 + K^0$ interaction. The hyperons were produced in a polyethylene target and their decays $\Lambda^0 \rightarrow p + \pi^-$ were detected in an emulsion stack. From 49 events the magnetic moment of Λ^0 was determined to be $\mu_{\Lambda^0} = -0.67 \pm 3$ nm. (L.B.S.)

59295 ANTI-LAMBDA PRODUCTION IN K^+p INTERACTIONS AT 8.25 GeV/c. Charriere, G. (CERN, Geneva); Drijard, D.; Dunwoodie, W.; (and others). Nucl. Phys.; B22: No. 2, 333-42 (1970).

We present the data on the $\bar{\Lambda}(\bar{\Sigma})$ events produced in final states of K^+p interactions at 8.25 GeV/c. Cross sections for $\bar{Y}^0$ production are given for most final states obtained in this experiment, and the results at other energies are listed for comparison. No significant enhancement is seen in the $\bar{Y}^0$ N mass distributions while there is some indication of the production of $\bar{Y}^*(1385)$ and $N^*(1236)$ in the $\bar{\Lambda}\pi$ and $N\pi$ systems respectively. An attempt at the description of the reaction $K^+p \rightarrow \bar{\Lambda}pp$ in terms of a five-point Veneziano amplitude is also included. (auth)

59296 $\pi\pi$ SCATTERING EFFECTS IN π^+p INTERACTIONS AT 8 GeV/c. Bartsch, J. (Technische Hochschule, Aachen); Keppel, E.; Schulte, R.; (and others). Nucl. Phys.; B22: No. 1, 1-15(1970).

The reaction $\pi^+p \rightarrow \Delta^{++}\pi^+\pi^-$ at 8 GeV/c was used to study $\pi\pi$ scattering in the ρ-meson mass region. Two different methods were used. In the first, it is assumed that $\pi\pi$ scattering in this mass range is entirely elastic and confined to S-, P- and D-waves. The P- and D-waves are assumed to be given by the ρ^0 and f^0 resonant amplitudes extrapolated off-shell using Dürr–Pilkuhn form factors. The remaining cross section (which by our assumption is S-wave) fits a Breit–Wigner distribution with $m_S = 680 \pm 30$ MeV and $\Gamma_S^0 = 310 \pm 70$ MeV. In the second method a $\pi\pi$ phase-shift analysis was used to obtain the S-wave phase shifts. There are two possible solutions here, one of which resonates at $m_S = 710 \pm 80$ MeV and $\Gamma_S^0 = 140 \pm 20$ MeV. (auth)

59297 STUDY OF CROSS SECTIONS AND SPIN-DENSITY MATRIX ELEMENTS FOR TWO-BODY REACTIONS IN 5 GeV/c π^+p TWO-PRONGED INTERACTIONS. Schotanus, D. J. (Univ., Nijmegen, Netherlands); Pols, C. L.; Toet, D. Z.; (and others). Nucl. Phys.; B22: No. 1, 45-65(1970).

Results are presented on differential (total) cross sections and decay parameters for four two-body reactions ($\pi^+p \rightarrow p\pi^+$, $\pi^+p \rightarrow p\rho^+$, $\pi^+p \rightarrow \Delta^{++}\pi^0$ and $\pi^+p \rightarrow \Delta^{++}\eta^0$) obtained from a sample of approximately 30,000 two-pronged interactions at 5 GeV/c incident momentum. In the forward direction the $d\sigma/dt'$ distribution of reactions $p\rho^+$, $\Delta^{++}\pi^0$ and $\Delta^{++}\eta^0$ shows a dip or flat region. The general $d\sigma/dt'$ structure of the elastic channel and the reaction $p\rho^+$ requires a "double-slope" fit. The $d\sigma/dt'$ distribution of reaction $\pi^+p \rightarrow \Delta^{++}\pi^0$ shows a clear-cut dip at $t' \approx 0.6$ GeV^2. In the backward region peaks are observed for reactions $\pi^+p \rightarrow p\pi^+$, $p\rho^+$ and $N^{*+}(1660)\pi^0$. The $d\sigma/d|u|$ distribution of the elastic channel shows a dip at $|u| \approx -0.2$ GeV^2. The spin-density matrix elements of the ρ^+ particle in reaction $p\rho^+$ indicate the presence of both π- and ω-trajectory exchange. The spin-density matrix elements of the Δ^{++} in the reactions with final state $\Delta^{++}\pi^0$ and $\Delta^{++}\eta^0$ are compatible with pure ρ and A_2 Regge trajectory exchange respectively. Where applicable, the $d\sigma/dt'$ and density matrix element results are compared with the Dar–Weisskopf absorption model and with the predictions resulting from Regge-pole model fits. (auth)

59298 **g-MESON. Bartsch, J. (Technische Hochschule, Aachen); Kraus, G.; Tsanos, N.; (and others). Nucl. Phys.; B22: No. 1, 109-30(1970).**

The present status of our knowledge of the properties of the g-meson is summarized and discussed. New results obtained by the ABC collaboration in an 8 GeV/c π^+p experiment, concerning $(2\pi)^+$ and $(4\pi)^+$ enhancements at about 1700 MeV, are presented. For the question of the g-meson spin, it is shown that the two types of determinations based on analyses of the decay angular distributions published in the literature, as well as the analysis attempted on these 8 GeV/c results, all favoring $J^P = 3^-$, cannot be considered as definitive. A third method of spin analysis is here tried, based on a study of the g-meson cross section as a function of the g-meson spin and elasticity, using the OPE model. This new method is a general one which could be applied to other resonances with production mechanism similar to that of the g-meson. It is found that in the framework of this model, (a) irrespective of the spin assignment, the g-meson must have elasticity $\eta < 1$, which means that the $g \rightarrow 2\pi$ and at least part of the 4π enhancement are the same object, (b) assuming that all the 4π enhancement derives from the g-meson, the experimental value of the elasticity $\eta \approx 0.4$ favors $J^P = 3^-$. (auth)

59299 SIX- AND SEVEN-BODY FINAL STATES IN K^+p INTERACTIONS AT 5 GeV/c. **De Baere, W. (Laboratoire Interuniversitaire Belge des Hautes Energies, Brussels); Debaisieux, J.; De Wolf, E.; (and others). Nucl. Phys.; B22: No. 1, 131-49(1970).**

A study of six- and seven-body final states among the K^+p interactions at 5 GeV/c incident K^+ momentum is presented. Results on cross sections, resonance and single-particle productions are given. Charge dependent angular correlations for pairs of pions occur as in $\bar{p}p$ and π^+p interactions (the so called GGLP effect). In contrast, no dependence on the charge is observed in the angular correlations between kaons and pions. The influence of the production of K^* and N^* resonances on these angular correlations is investigated. The predictions of a multi-Regge Model (CLA) are compared to the experimental results. (auth)

59300 APPLICATION OF A MULTI-REGGE MODEL TO THE REACTION $\pi^-p \rightarrow p\pi^+\pi^-\pi^-\pi^0$ AT 13 AND 20 GeV/c. Brandenburg, G. W.; Brenner, A. E.; Heyda, D.; (and others) (Harvard Univ., Cambridge, Mass.). Nucl. Phys.; B22: No. 1, 157-78(1970).

Data from the reaction $\pi^-p \rightarrow p\pi^+\pi^-\pi^-\pi^0$ at 13 and 20 GeV/c are compared with the predictions of the Reggeized multiperipheral model of Chan, Łoskiewicz and Allison. The model is in good agreement with the single-particle momentum distributions and adequately reproduces the shape of the non-resonant regions of the invariant-mass distributions. (auth)

59301 REACTION $\pi^-p \rightarrow K^+K^-n$ BETWEEN 988 AND 1100 MeV INVARIANT KK MASS. Hyams, B. D. (CERN, Geneva); Koch, W.; Potter, D. C.; (and others). Nucl. Phys.; B22: No. 1, 189-204(1970).

The results of an optical spark chamber experiment studying the reaction $\pi^-p \rightarrow K^+K^-n$ at 11.04 GeV/c π^- momentum are studied. The apparatus measured the K^+K^- system over all decay orientations up to a mass of 1100 MeV and $|t| \leq 0.5$ (GeV/c)^2. The observed mass spectrum comprises a superposition of a slowly varying S-wave and P-wave, the ϕ-resonance, and a small bump at 1063 MeV. The spin-density matrix elements of the K^+K^- system are presented and discussed. The ϕ-mass and width were determined to be $M = 1018 + 0.5(-0.35)$ MeV, $\Gamma = 3.3 + 1.5 (-0.9)$ MeV. (auth)

59302 K^-d ELASTIC SCATTERING AND $K^-d \rightarrow K^-pn$ BETWEEN 810 AND 1110 MeV/c. Jew, N. N.; Kalmus, G. E. (Univ. of California, Berkeley). Nucl. Phys.; B22: No. 1, 205-24(1970).

Angular distributions for the reactions $Kd \rightarrow Kd$ and $Kd \rightarrow Kpn$ at incident K^- momenta of 810, 910, 1010 and 1110 MeV/c are presented. Data are also presented on K^-n elastic scattering assuming the impulse approximation is valid. (auth)

59303 PARTIAL WAVE ANALYSIS OF $K^-N \rightarrow \Lambda\pi$ BETWEEN 1.0 AND 1.85 GeV/c. Litchfield, P. J. (Rutherford High Energy Lab., Chilton, Eng.). Nucl. Phys.; B22: No. 1, 269-84(1970).

A partial wave analysis was performed on a compilation of the world's data on the reaction $K^-N \rightarrow \Lambda\pi$ in the range of incident beam momenta between 1.0 and 1.85 GeV/c. The resonance parameters of the $F_7\Sigma(2030)$ are determined to be: mass = 2022 ± 4 MeV, width = 170 ± 15 MeV and $\sqrt{(xx')} = +0.200 \pm 0.008$ and those of the $F_5\Sigma(1910)$ to be: mass = 1895 ± 10 MeV, width = 70 ± 15 MeV, $\sqrt{(xx')} = -0.070 \pm 0.015$. Evidence is also found for resonant behavior in the P_1 wave at 1920 MeV, in the P_3 wave at 2070 MeV and in the D_3 wave at 1940 MeV. (auth)

59304 PARTIAL WAVE AMPLITUDES FOR π^-p ELASTIC SCATTERING AND CHARGE EXCHANGE IN THE 2 TO 5 GeV/c REGION. Roychoudhury, R. K.; Perrin, R.; Bransden, B. H. (Univ. of Durham, Eng.). Nucl. Phys.; B22: No. 2, 573-82(1970).

The experimental data, for the elastic scattering of π^- mesons by protons and for charge exchange in the momentum interval 2 to 5 GeV/c, was fitted by a model in which the amplitudes are represented as the sum of Regge-pole exchange terms and parametric terms based on polynomial expansions in cos θ. Phase-shift parameters are subsequently obtained by partial wave projection, and the resonant structure of the region is tentatively identified. (auth)

59305 **K^+N CHARGE-EXCHANGE REACTION AT 5.5 GeV/c. Cline, D.; Penn, J.; Reeder, D. D. (Univ. of Wisconsin, Madison). Contract AT(11-1)-881. Nucl. Phys.; B22: No. 1, 247-52(1970).**

The partial cross section and momentum transfer distribution for the reaction $K^+d \rightarrow K^0pp$ was measured at 5.5 GeV/c. The cross section is 174.8 ± 20.0 μb. The differential cross section in the forward direction is compared to the optical point and the KN charge-exchange scattering amplitude is found to be predominately real. A comparison of the data to Regge models and SU(3) sum rules is made. (auth)

59306 EXPERIMENTAL DETERMINATION OF THE LOW MASS I = 0 S-WAVE $\pi\pi$ PHASE SHIFT USING A METHOD WHICH IS CONSISTENT WITH THE OFF-MASS-SHELL DEPENDENCE OF CURRENT ALGEBRA. Scharenguivel, J. H. (Purdue Univ., Lafayette, Ind.); Gutay, L. J.; Miller, D. H.; Meiere, F. T.; Marateck, S. Nucl. Phys.; B22: No. 1, 16-30(1970).

The forward-backward asymmetry $\alpha(s,\Delta^2)$ was extrapolated to both the pion pole and to the $\pi\pi$ threshold in a manner that is consistent with the general form of the off-mass-shell dependence of current algebra. The P-wave and the isoscalar S-wave $\pi\pi$ phase shifts near threshold were determined. (auth)

59307 ANALYSIS OF THE N*(1500) AND N*(1700) BARYON RESONANCES PRODUCED VIA DIFFRACTION DISSOCIATION. **Morse, R. (Univ. of Wisconsin, Madison); Oh, B. Y.; Walker, W. D.; (and others). Contract AT(11-1)-881. Phys. Rev., D; 4: No. 1, 133-40(1 Jul 1971).**

Evidence in the $\pi\pi N$ mass spectrum for the production of two nucleon isobars, the N*(1500) and N*(1700), is reported. They appear to be produced very peripherally, and have the same production cross section at both 7.0 and 25.0 GeV/c, indicating that a nuclear diffraction-dissociation process is dominant. The N*(1500) seems to be $J^P = \frac{1}{2}^+$ and decays principally via $p\sigma$ and not $\Delta^{++}\pi^-$ as previously suggested. The N*(1700) could be the N*(1688) $\frac{5}{2}^+$ decaying partially into $\Delta^{++}\pi^-$, or it could be the N*(1700) $\frac{1}{2}^-$ decaying in a non-$\Delta^{++}\pi^-$ mode riding on a large $\Delta^{++}\pi^-$ $\frac{5}{2}^+$ nonresonant Deck-type background. Finally the ΛK decay of the N*(1700) is observed and evidence presented for it being a $J = \frac{1}{2}$ object. Production of this $\frac{1}{2}^-$ isobar should be forbidden by the Morrison $\Delta P = (-1)^{\Delta J}$ rule. (auth)

59308 EVIDENCE FOR A CHARGE ASYMMETRY ON THE ω DALITZ PLOT. Abrams, G. S.; Barnham, K. W. J.; Butler,

XUM

W. R.; (and others) (Univ. of California, Berkeley). Phys. Rev., D; 4: No. 3, 653-63(1 Aug 1971).

The reaction $\pi^+p \rightarrow \pi^+p\omega$ was studied at 3.7 GeV/c using data from the LRL 72-in. hydrogen bubble chamber. An analysis of the $\omega \rightarrow \pi^+\pi^-\pi^0$ Dalitz plot for ~4000 ω events yields no evidence for $\pi^+\pi^-\pi^0$ states with isospin $I \neq 0$ at the level of 10^{-3} in intensity relative to the $I = 0$ intensity. A similar analysis of ~500 ω events produced in a kinematical region of known $\rho-\omega$ coherence yields no evidence for $\rho^0 \rightarrow \pi^+\pi^-\pi^0$ decays with $I \neq 0$ at the 1% level in intensity relative to the $\rho^0 \rightarrow \pi^+\pi^-$ mode. A significantly nonzero value of the charge asymmetry $\alpha = (N_+ - N_-)/(N_+ + N_-)$ is observed (0.179 ± 0.051) for ω events produced opposite a $\Delta^{++}(1236)$ in the narrow $t' = |t - t_{min}|$ range [0.08 – 0.20 $(GeV/c)^2$]. Four possible origins for the observed interfering amplitude are discussed, whose quantum assignments may be deduced as $I^G = 1^-$, $J^{PC} = 1^{-+}$: (1) C violation in ω decay (which may be ruled out), (2) C violation in $\rho^0 \rightarrow \pi^+\pi^-\pi^0$ decay, (3) a miscellaneous coherent background amplitude with these quantum numbers, and (4) a possible exotic resonant state with these quantum numbers. (auth)

59309 π^+p ELASTIC SCATTERING DATA BETWEEN 1820- AND 2090-MeV c.m. ENERGY. Kalmus, G. E. (Univ. of California, Berkeley); Michael, W.; Birge, R. W.; Fung, S. Y.; Kernan, A. Phys. Rev., D; 4: No. 3, 676-83(1 Aug 1971).

Total and differential elastic cross section data are presented at eight incident π^+ momenta: 1.28, 1.34, 1.40, 1.43, 1.55, 1.68, 1.77, and 1.84 GeV/c. These data were obtained from a hydrogen-bubble-chamber exposure at the Bevatron, and contain more than 65,000 events. This represents more than 1½ times the world's data hitherto available in this energy region. (auth)

59310 BRANCHING RATIO FOR THE DECAY OF ϕ MESONS INTO LEPTON PAIRS. Hayes, S.; Imlay, R.; Joseph, P. M.; Keizer, A. S.; Stein, P. C. (Cornell Univ., Ithaca, N. Y.). Phys. Rev., D; 4: No. 3, 899(1 Aug 1971).

Values of the branching ratio for the decay of ϕ mesons into lepton pairs obtained from colliding-beam experiments are compared with values obtained from photoproduction experiments. (auth)

59311 ADDITIONAL DATA IN THE REACTION $\pi^+p \rightarrow \Sigma^+K^+$ AT 1.28 AND 1.41 GeV/c AND A TEST OF CHARGE INDEPENDENCE IN THE c.m. ENERGY RANGE 1.820 TO 2.090 GeV. Kalmus, G. E.; Borreani, G.; Louie, J. (Univ. of California, Berkeley). Phys. Rev., D; 4: No. 3, 916-18(1 Aug 1971).

Data at two additional π^+ momenta (1.28 and 1.41 GeV/c) in the reaction $\pi^+p \rightarrow \Sigma^+K^+$ are presented. Charge independence is tested over the c.m. energy range 1.820 to 2.090 GeV; the data for the Σ^+K^+ channel and published data for the $\pi^-p \rightarrow \Sigma^0K^0$ and Σ^-K^+ channels were used. (auth)

59312 INVESTIGATION OF THE REACTION $\pi^-p \rightarrow pX^-$ AT THE MOMENTUM OF 3.25 GeV/c WITH HIGH MOMENTUM TRANSFER. Baloshin, O. N.; Vladimirskii, V. V.; Dukhovskoi, I. A.; (and others) (Inst. of Theoretical and Experimental Physics, Moscow). Yadern. Fiz.; 14: No. 1, 131-3(Jul 1971). (In Russian).

The missing mass spectrum for the reaction $\pi^-p \rightarrow pX^-$ is investigated at high momentum transfers by means of the track spectrometer with optical spark chambers in a magnetic field. The initial π^--meson momentum is 3.25 GeV/c. The ρ^--meson production differential cross section is measured in the angle interval $-1.0 \leq \cos\theta^* \leq -0.995$, that is found to be 28.2 ± 9.8 μbarn/sterad. (auth)

59313 COHERENT INTERACTIONS OF PIONS WITH NUCLEAR EMULSION AT ENERGIES OF 17 AND 45 GeV. Azimov, S. A.; Basova, E. S.; Grishin, V. G.; (and others) (Inst. of Nuclear Physics, Tashkent). Yadern. Fiz.; 14: No. 1, 137-49 (Jul 1971). (In Russian).

A method is described to select coherent interactions of high energy particles with complex nuclei that is based on analysis of the two-dimensional distributions of the angular estimates of the longitudinal and transversal momenta, transfered to the target nucleus, in various interaction groups. With this method the mean free paths are obtained for the coherent reactions $\pi^- \rightarrow 2\pi^-\pi^+$ and $\pi^- \rightarrow 3\pi^-2\pi^+$ on the emulsion nuclei at the pion energy of 17 GeV: $52.8^{+6.5}_{-5.2}$ m and $3.8^{+1.5}_{-1.6}$ km respectively; and at the energy of 45 GeV the mean free paths are obtained to be $34.0^{+5.5}_{-4.1}$ m and 195^{+108}_{-52} m. (auth)

59314 π^-p INTERACTIONS AT 3.25 GeV/c. TWO-PRONG EVENTS. Guzhavin, V. M.; Vetlitskii, I. A.; Kaidalov, A. B.; (and others) (Inst. of Theoretical and Experimental Physics, Moscow). Yadern. Fiz.; 14: No. 2, 354-66(Aug 1971). (In Russian).

Two-prong events of π^-p interactions at the incident π^--meson momentum of 3.25 GeV/c were studied using a liquid-hydrogen bubble chamber. The cross sections of certain channels were determined. They were found to be 7.3 ± 0.5; 2.0 ± 0.2; 3.2 ± 0.3; 2.9 ± 0.3; 6.2 ± 0.5 mbn, respectively. It is shown that two reactions in 80% of all the cases occur as quasi-two-particle states. It is found that ρ^- and ρ^0 mesons are produced peripherally and their production cross section is 1.0 ± 0.2 mbn and 1.2 ± 0.2, respectively. The data on the experimental production cross section and on the elements of the ρ^- and ρ^0 meson polarization density matrix were described using two models: the Regge pole model (RPM) and the model accounting both Regge poles and moving branch points (RPMB). In terms of the RPM the contributions of the π, R Regge trajectories into the cross section of reaction $\pi^-p \rightarrow n\rho^0$ (~72%, 28%, respectively) and of R, ω poles into the cross section of reaction $\pi^-p \rightarrow p\rho^-$ (41%) are determined. When describing the experimental data using the RPMB it is shown that the contribution of the πP branch point into the cross section of certain processes and is small. It is found that both models describe satisfactorily the experimental results. (auth)

59315 ANALYSIS OF THE REACTION $\pi^+p \rightarrow \rho^0\Delta^{++}$ AT 11.7 GeV/c INCIDENT MOMENTUM. I. EXPERIMENTAL INVESTIGATION. Maddock, R. O. (Univ. of Durham, Eng.); Pinter, G. F.; Evans, D.; (and others). Nuovo Cim.; 5A: No. 3, 433-56 (1 Oct 1971).

The difficulty in determining the total and the differential cross sections of the double-resonance process $\pi^+p \rightarrow \rho^0\Delta^{++}$ is discussed and a method of determining these is given which involves only few theoretical assumptions. The total cross section is (0.32 ± 0.04) mb. The joint decay angular distribution is analysed in terms of statistical tensor and density matrix elements. The data are consistent with pion exchange. (auth)

59316 PRODUCTION OF $\pi^+2\pi^-$ SYSTEM ON NUCLEI AT SMALL MOMENTUM TRANSFERS. Kirillov-Ugryumov, V. G.; Levina, V. I.; Ponosov, A. K.; Protasov, V. P.; Sergeev, F. M. (Moscow Engineering Physics Inst.). JETP Lett. (USSR) (Engl. Transl.); 14: No. 3, 110-12(5 Aug 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 3, 168-71(5 Aug 1971).

The coherent production of a triplet of pions on light nuclei by π^- with 4 GeV/c momentum was observed in a freon bubble chamber. The mass distributions and cross sections are shown. It is noted that the mass distributions obtained hardly differ from the distributions for higher energies, when the fraction of the coherent reactions is much higher. (J.F.P.)

59317 PARTICLE MOMENTUM DISTRIBUTION FOR 8.5-GeV/c π^+p INTERACTIONS. Cole, J.; Lee-Franzini, J.; Loveless, R. J. (State Univ. of New York, Stony Brook). Phys. Rev., D; 4: No. 3, 627-30(1 Aug 1971).

Two-, four-, six-, and eight-prong events from 8.5-GeV/c π^+p interactions were measured and laboratory distributions of particle momenta were prepared both for the individual classes of events and for the combined sample. (auth)

59318 OBSERVATION OF A NEW $K_N(1760)$ IN THE $K\pi$ AND $K\pi\pi$ SYSTEMS. Carmony, D. D. (Purdue Univ., Lafayette, Ind.); Cords, D.; Clopp, H. W.; (and others). Phys. Rev. Lett.; 27: No. 17, 1160-3(25 Oct 1971).

A new K* resonance, denoted $K_N(1760)$, was observed. Its mass is 1759 ± 10 MeV; and its width, 60 ± 20 MeV. It is assigned to the natural-spin–parity series on the basis of 5-standard-deviation evidence for a $K\pi$ decay mode. Decays into $K^*(890)\pi$ and $K\rho$ with the same mass and width are observed with 4-standard-deviation significance. It is suggested that this state is the analog of the g meson. In addition, evidence for further high-mass structure was seen. (auth)

59319 LIMITING DISTRIBUTIONS FOR TARGET FRAGMENTATION IN THE REACTIONS $\pi^\pm + p \rightarrow \pi^- +$ ANYTHING. Shephard, W. D. (Univ. of Notre Dame, Ind.); Powers, J. T.; Biswas, N. N.; (and others). Contract AT(11-1)-881. Phys. Rev. Lett.; 27: No. 17, 1164-7(25 Oct 1971).

The inclusive reactions $\pi^- + p \rightarrow \pi^- +$ anything at 8, 18.5, and 24.8 GeV/c and $\pi^+ + p \rightarrow \pi^- +$ anything at 18.5 GeV/c were studied. Distributions of the particle density $\omega(d\sigma/dp_{||})/(\sigma_T)_\infty$ at $p_{||} \lesssim 1$ GeV/c for the "inclusive" π^- indicate an approach to limiting behavior for π^+p at current accelerator energies. Invariant cross sections for π^-p decrease significantly in magnitude as the incident energy increases. The decrease is consistent with an energy dependence similar to the form $A + Bs^{-1/2}$ suggested by Regge phenomenology, with the π^-p distribution approaching the π^+p limiting distribution as a limit. (auth)

59320 EXPERIMENTAL STUDY OF ω NEUTRAL DECAYS. Datin, J. T.; Hauser, M. G.; Kreisler, M. N.; Mischke, R. E.; Ritsko, J. J. (Princeton Univ., N. J.). Contract AT(30-1)-4159. Phys. Lett.; 36B: No. 6, 607-10(18 Oct 1971).

The neutral branching ratios of the ω meson were determined by measuring the c.m. momentum spectrum of single γ's from ω decay. The sample of 400 ω events after background subtraction yields an upper limit of $(\omega \rightarrow \eta\gamma)/(\omega \rightarrow \text{neutrals}) < 25\%$ (90% confidence). The fit with $\omega \rightarrow \pi^0\gamma$ only cannot be excluded. However, the best fit is obtained with the ratios $(\omega \rightarrow \pi^0\gamma)/(\omega \rightarrow \text{neutrals}) = (78 \pm 7)\%$ and $(\omega \rightarrow \pi^0\pi^0\gamma)/(\omega \rightarrow \text{neutrals}) = (22 \pm 7)\%$. 59321 (JINR-E2-5993) TRANSFORMATION PROPERTIES OF STATES AT INFINITE MOMENTUM II. Robaschik, D.; Smorodinskii, Ya. A.; Wieczorek, E. (Joint Inst. for Nuclear Research, Dubna (USSR). Lab. of Theoretical Physics). 1971. 13p. Dep. NTIS (U. S. Sales Only).

The well known result, that helicity states of massive particles at infinite momentum satisfy the same transformation laws as the states of massless particles, is extended to the states with $p^2 < 0$. In the cases $p^2 > 0$ and $p^2 < 0$ canonical states are defined. The asymptotic properties of the Wigner rotation for these states are considered. A connection is given between the Wigner rotation in the infinite momentum limit and the rotation in the corresponding subspace induced by the transformation of an appropriate light-like vector. (auth)

59322 (NP-19024) REMARKS ON INCLUSIVE EXPERIMENTS AND HIGH ENERGY MODELS. Note No. 310. Boldrighini, C.; Lusanna, L.; Sertorio, L. (Rome Univ. (Italy). Istituto di Fisica). 2 Apr 1971. 12p. Dep. NTIS (U. S. Sales Only).

The models discussed are the multiperipheral, multi-Regge, and dual. The average multiplicity and average perpendicular momentum for the high-energy interactions are intimately connected with each other in the models considered and also connected to the asymptotic behavior of the absorptive part of the elastic amplitude. These connections are discussed. (J.F.P.)

59323 RECENT PROGRESS IN CURRENT ALGEBRA. Fubini, S. (Univ., Turin). pp 401-14 of Methods and Problems of Theoretical Physics. /Bowcock, J. E. (ed.). New York; American Elsevier Publishing Co., Inc. (1970).

From Conference on methods and problems of theoretical physics; Birmingham, England (Jun 1967).

59324 ALGEBRA OF FIELDS. Lee, T. D. (Columbia Univ., New York). pp 415-20 of Methods and Problems of Theoretical Physics. /Bowcock, J. E. (ed.). New York; American Elsevier Publishing Co., Inc. (1970).

From Conference on methods and problems of theoretical physics; Birmingham, England (Jun 1967).

59325 MOTION OF A PARTICLE IN A REFRACTING MEDIUM. de Broglie, Louis Compt. Rend., Ser. B; 272: No. 24, 1333-5(14 Jun 1971). (In French).

A dynamic problem with variable rest mass is studied in the framework of the double solution theory. The particle considered moves in a refracting and possibly dispersing medium. (France)

59326 EXCITING WORLD OF HADRON PHYSICS. Squires, E. J. (Durham Univ., Eng.). Phys. Bull. (London); 22: 517-20 (Sep 1971).

The world of hadron physics consists of a large body of complex experimental information, some of which shows surprisingly simple patterns and regularities but essentially none of it is understood. Most theoretical work consists in finding clever ways of presenting the data and explanations are, in general, lacking. Questions raised by the experimentalists work are considered, such as: What dominates high energy scattering or what is the pomeron? Do Regge poles factorize? Where are baryon parity doublets? Where are the zeros of scattering amplitudes and why? Why are mesons and baryons so different? These may not be the most fundamental questions but those for which it is hoped answers will be found in the near future. (UK)

59327 ANGULAR DISTRIBUTION OF PARTICLES PRODUCED IN MULTIPLE PROCESSES. Daibog, E. I.; Rozental, I. L. (Inst. of Cosmic Research, Moscow). Yadern. Fiz.; 14: No. 1, 226-31(Jul 1971). (In Russian).

General reasons for the two-bump structure of the distributions in logarithmic coordinates are considered. It is shown that in the c.m. frame the two-bump structure is present at sufficiently high primary energy and practically at every total momentum distribution. Preservation of the two-bump structure in the lab. frame depends on the relative content of the nonrelativistic particles in the showers. General conditions for the presence of the two-bump structure in the lab. frame are established for a large class of distributions on the total momentum. The experimental presence of a small (~20%) amount of the "two-bump" events is explained as the result of fluctuations of the portion of slow particles. (auth)

59328 POLARIZATION PROPERTIES OF PARTICLES PRODUCED AT HIGH ENERGIES. Karnakov, B. M. (Moscow Engineering-Physics Inst.). Yadern. Fiz.; 14: No. 2, 454-7 (Aug 1971). (In Russian).

It is noted that if the high-energy asymptotics of a process $a + b \rightarrow A + B$ is dominated by a single boson Regge pole and when the polarization state of a particle a (or b) is "pure" (i.e., $\rho^2_{a(b)} = \rho_{a(b)}$), the spin state of the particle A (or B) is also "pure." Deviation of $\rho^2_{A(B)}$ from $\rho_{A(B)}$ indicates a presence of several Regge poles or the j-plane branch points. The case of partial polarization of the colliding particles is discussed. (auth)

59329 VIOLATION OF THE POMERANCHUK-THEOREM CONDITIONS AND THE ODD-SIGNATURE AMPLITUDE. Fukuda, R. (Tokyo Univ.). Phys. Rev., D; 4: No. 3, 830-3(1 Aug 1971).

The properties of the odd-signature amplitude are discussed in the case that the total cross sections of the particle and antiparticle tend to constant but different limits at high energy. The imaginary and real part of the odd-signature amplitude must be correlated by a simple relation and also be subjected to various stringent conditions. Sum rules are obtained that can be used as a test of the violation of the Pomeranchuk theorem. A specific model is proposed satisfying these conditions, and some consequences are discussed. (auth)

59330 EIKONAL APPROXIMATION FOR INELASTIC PROCESSES. Harrington, David R. (Rutgers-The State Univ., New Brunswick, N. J.). Phys. Rev., D; 4: No. 3, 840-8(1 Aug 1971).

The eikonal approximation for the contributions to inelastic scattering from arbitrarily crossed ladder graphs is considered. The particle represented by one of the "sidepieces" of the ladders is allowed to change its state and mass at each rung; the other sidepiece particle is restricted to have at most one change of state, and that only if its elastic interactions are the same in the two states. When the denominators of the latter sidepiece can be linearized, the amplitudes reduce to forms essentially identical to those found in nonrelativistic coupled-channel potential theory. This result is independent of the ratio of the energy to the sidepiece mass and connects smoothly the nonrelativistic and extreme relativistic regimes. Its implications for absorptive models are discussed briefly. (auth)

59331 SUM RULES FOR INCLUSIVE CROSS SECTIONS. DeTar, C. E.; Freedman, D. Z.; Veneziano, G. (Massachusetts Inst. of Tech., Cambridge). Phys. Rev., D; 4: No. 3, 906-9 (1 Aug 1971).

In generalization of known results, rigorous sum rules are presented for inclusive cross sections based upon conservation of momentum or of any additive discrete quantum number. Included are formulas which normalize inclusive cross sections in terms of σ_{total} independently of multiplicities. The sum rules could be useful in constraining theoretical models which construct inclusive cross sections without detailed reference to exclusive processes. Some applications are described and a generalization to the tensors governing weak and electromagnetic inclusive reactions is given. (auth)

59332 FEYNMAN'S RELATION FOR PARTICLE PRODUCTION NEAR THE BOUNDARY OF PHASE SPACE. Elitzur, Moshe (Rockefeller Univ., New York). Phys. Rev., D; 4: No. 3, 910-12(1 Aug 1971).

Feynman's relation for one-particle inclusive experiments at the edge of the fragmentation region is derived using only quasi-two-body amplitudes and single-Regge-pole exchange. A similar relation for two-particle inclusive experiments is also derived. (auth)

Electromagnetic

59333 (JINR-E2-6036) DEEP INELASTIC ELECTROPRODUCTION OF HADRONS ON A PHOTON TARGET. Kunszt, Z.; Ter-Antonyan, V. M. (Joint Inst. for Nuclear Research, Dubna (USSR). Lab. of Theoretical Physics). 1971. 13p. Dep. NTIS (U. S. Sales Only).

The inelastic scattering ee → eeN hadrons, on the condition that one of the final state electrons is detected at large angles, is discussed. A simple estimate shows that this process may make possible the observation of the deep inelastic electroproduction of hadrons on a photon target. (auth)

59334 (LNF-71/14) OBSERVATIONS ON THE PRODUCTION OF HADRONS BY MEANS OF THE LANDAU-LIFSHITZ PROCESS. Parisi, G.; Testa, M. (Comitato Nazionale per l'Energia Nucleare, Frascati (Italy). Laboratori Nazionali di Frascati). 31 Mar 1971. 5p. (In Italian). Dep. NTIS (U. S. Sales Only).

The cross section for the production of hadrons is calculated on the assumption that part of the hadron processes observed with crossed e^+e^- beams result from the interaction of the electromagnetic fields created by the electrons and positrons. (J.S.R.)

59335 TAMAGAKI AND HAMADA-JOHNSTON POTENTIALS AND ELASTIC ELECTRON-DEUTERON SCATTERING. Pask, Colin (Univ. of South Wales, Kensington, Australia). Progr. Theor. Phys. (Kyoto); 46: No. 1, 336-8(Jul 1971).

A comparison is made between the Tamagaki and Hamada-Johnston potentials by examining elastic electron-deuteron scattering results. It is found that the calculations show differences between the two potentials, but the differences only become significant when the nonrelativistic model used begins to break down. It is concluded that the method used does not lead to a clear unambiguous result. (L.B.S.)

59336 MONOCHROMATIC RADIATION FROM A COHERENT MODULATED BEAM OF CHARGED PARTICLES. Favro, L. D.; Fradkin, D. M.; Kuo, P. K. (Wayne State Univ., Detroit). Phys. Rev. Lett.; 25: 202-4(27 Jul 1970).

It is suggested that intense laser fields may be used to modulate the wave functions of electrons. A classical model is used to demonstrate the greatly altered radiation fields of these electrons after they emerge from the laser beam. The observation by Schwarz and Hora of visible radiation from a nonluminescent target appears to result from these fields. (auth)

59337 RELATIVISTIC MODEL FOR THE ELECTRO- AND WEAK PRODUCTION OF NUCLEON RESONANCES. Zucker, Paul Alan. Stanford, Calif.; Stanford Univ. (1971). 210p. University Microfilms Order No. 71-19,786.
Thesis.

A model was developed to describe the electro- and weak production of nucleon resonances off of nucleon targets. The helicity amplitudes which describe these processes are calculated in the model by choosing a covariant and gauge-invariant (a partially conserved axial current is used for the weak case) set of exchange graphs thought to play an important role as an excitation mechanism. The projection of the exchange graphs into the partial wave channel under consideration is then multiplied by a final-state enhancement factor which provides a resonance mechanism. It is shown how this model incorporates unitarity as an approximate solution to the Omnès equation and how it also obeys the threshold, covariance, and analyticity requirements of the processes in question. Since one is primarily interested in the resonances at energies above 1236 MeV, one is forced to confront the problem of inelastic hadronic scattering. The procedure is then to perform a coupled-channel calculation keeping the $|\pi N\rangle$ and $|\pi N^*(1236)\rangle$ channels as intermediate states and assume that one hadronic eigenphase shift is resonant. The final-state enhancement factor is then determined in terms of an integral over the eigenphase shift. As input, the experimentally determined phase shifts for pion-nucleon scattering are used. The π,N, and vector meson exchange is kept as the excitation mechanism and some N*(1236) exchange is included as well. For the elastic form factors the known values are used and the model then predicts the inelastic form factors for resonance excitation. Also the widths and locations of the resonances as they are observed in electro- or weak production are predicted. The electroproduction predictions are compared with the subsequent experimental results from SLAC and are found to agree out to large values (~5 GeV^2) of k^2, the square of the four-momentum transferred from the leptons. For all four observed resonant peaks it was predicted that the ratio of the inelastic to elastic cross sections rises and then levels off abruptly at small k^2, remaining constant out to large k^2. The extent of this rise (typically one or two decades in the SLAC experiments) and the region where the ratio levels off are predictions which are particularly model dependent. It is also predicted that the spin ½ resonances are unimportant in electroproduction, based on their small observed contribution to photoproduction. Interestingly, a one-channel model, keeping only the $|\pi N\rangle$ intermediate state, worked well for the integrated electroproduction cross sections (but it gave predictions for the individual inelastic form factors noticeably different from those of the two-channel calculation). In predicting the integrated weak production cross sections (related experiments are being planned, for example, at Brookhaven and at the National Accelerator Laboratory), this simpler one-channel calculation was used. For this process an explicitly conserved vector current and partially conserved axial current were kept, and the results obey the forward lepton theorem when the scattering angle is zero. (Diss. Abstr.)

59338 CLASSICAL CHARGE SYMMETRIC THEORY OF THE PHOTOPRODUCTION OF SCALAR MESONS. Rosenblum, Arnold. Philadelphia; Temple Univ. (1971). 103p. University Microfilms Order No. 71-19,965.
Thesis.

The cross section for the photoproduction of scalar mesons is calculated on the basis of a classical charge-symmetric field theory. The form of the equations of motion of singularities of the nonlinear fields was determined exactly. The fields appearing in the equations of motion must be evaluated at the position of the nucleon. To do this, the nonlinear field equations which take into account the interaction between the meson and electromagnetic fields were solved in first order by a method of successive approximation based on expanding all field quantities in powers of the coupling constant e. The fields were evaluated at the nucleon position by making use of the method of Riesz potentials. The equations describing the motion of the particle in four space and of its isotopic spin in "charge space" were solved by assuming slow motion and small oscillations both for the actual motion of the nucleon and for the motion of the isotopic spin vector. It was found that the cross sections for the interacting case then reduce to the same result as in the noninteracting case. Incidental to these calculations, it is also found that in action-at-a-distance theory the cross sections in the interacting case are the same as the noninteracting ones and different from those of field theory. All results are shown to be consistent with the principle of detailed balance by consideration of the inverse processes. (Diss. Abstr.)

59339 NUCLEON FORM FACTOR AT HIGH ENERGIES. Ruck, H. M. Stud. Univ. Babes-Bolyai, Ser. Phys.; 16: No. 1, 25-7(1971).

The high-energy behavior of the nucleon form factor was studied by Jaffe (Phys. Rev. Lett. 17, 661(1966)) under the assumptions that the nucleon field is of type S and the momentum distribution of the nucleon field has a mass-gap. It is shown that in the final stage of the calculations a different procedure may be used following the theorem of Phragmen-Lindelof on regular functions. (L.B.S.)

59340 COMPTON SCATTERING AT HIGH ENERGIES. Shibasaki, Ichiro (Tokyo Univ.); Minamikawa, Toshiyuki; Watanabe, Tsunetoshi. Progr. Theor. Phys. (Kyoto); 46: No. 1, 173-89(Jul 1971).

Using the continuous moment sum rule it is found that the third vacuum pole P'' is important for the forward proton Compton scattering, and the residue of the fixed pole at $J = 0$ is also estimated. The third vacuum pole P'' has zero intercept $\alpha_{P''}(0) \cong -0.5$. The prediction of the high energy total cross section is consistent with recent experimental results. (auth)

59341 ON THE POSSIBILITY OF PRODUCING 0.1-GeV IONS BY FOCUSING ULTRASHORT LASER PULSES ON THIN FOILS. Caruso, A.; Gratton, R. (European Space Research Inst., Frascati, Italy). Phys. Lett.; 36A: No. 4, 275-6(13 Sep 1971).

The possibility of creating a high-energy neutralized ion beam (energy ≈ 1 MeV per nucleon), by a laser pulse, is considered. (auth)

59342 SOME CONSEQUENCES OF THE ASYMPTOTIC SCALING ASSUMPTION. Boiti, M.; Donini, E.; Pempinelli, F. (Univ., Lecce, Italy). Lett. Nuovo Cim.; 2: No. 14, 686-8(2 Oct 1971).

It is shown that the asymptotic scaling assumption for the structure functions νW_2 and W_1 of the electron-proton scattering process giving electron and hadrons constrains the longitudinal scaling amplitude for this process to be identically zero. (L.B.S.)

59343 ELECTROMAGNETIC INTERACTIONS OF COSMIC-RAY MUONS AT LARGE ZENITH ANGLES AT SEA LEVEL. Ashton, F.; Coats, R. B. (Univ. of Durham, Eng.). J. Phys., A (London); 4: No. 5, 649-59(Sep 1971).

The electromagnetic interactions of cosmic-ray muons incident at sea level in the zenith angle range 50 to 90° were studied. The measurements cover energy transfers from 3 to 240 GeV produced by muons in the energy range 34 to 520 GeV. No significant divergence from accepted theory was found. (auth)

59344 QUARK–MOLECULE CALCULATIONS. Goto, Eiichi (Tokyo Univ.); Matsuoka, Osamu; Kunii, Tosiyasu L. Phys. Rev., A; 4: No. 4, 1380-7(Oct 1971).

Electronic structures of hypothetical molecules containing quarks, or fractionally charged particles, are treated. By regarding the quark charge Q as a continuous variable, approximations satisfying a consistency condition at small-Q values are formulated. Their validity is checked with the exact solutions of the one-electron two-center problem and applied to two-electron two-center problems of H^--quark and He-quark molecules. (auth)

59345 QUANTUM-ELECTRODYNAMIC MODEL FOR PRODUCTION AMPLITUDES AT INFINITE MOMENTUM. Pardee, William Joseph. Urbana, Ill.; Univ. of Urbana (1971). 101p. University Microfilms Order No. 71-21,202.

Thesis.

The scattering amplitude for the production of an arbitrary number of electron-positron pairs in electron–electron collisions is calculated in an infinite momentum field theory model. More precisely, the model considers only events where the center of momentum energy is much larger than typical subenergies between pairs which are adjacent in longitudinal momentum. The subenergies are assumed much larger than masses and momentum transfers. The calculation is restricted to multiperipheral diagrams. In an approximation that neglects electron and photon masses, it is possible to obtain a simple form for the sum of all the partial cross sections generated by these diagrams. The number distribution P(n), the average number of pairs produced, the two particle and one particle momentum distributions and the total cross section are obtained. The two particle distribution is expressed in terms of the invariant mass, total longitudinal momentum, and transverse momenta of the pair. The contribution of these processes to the absorptive part of the elastic amplitude is studied for small t. (Diss. Abstr. Int., B)

59346 ELECTROPRODUCTION OF π^0: A CRUCIAL TEST OF DIP MECHANISMS. Harari, Haim (Stanford Univ., Calif.). Phys. Rev. Lett.; 27: No. 15, 1028-31(11 Oct 1971).

Dips in differential cross sections of inelastic hadronic reactions may be caused by nonsense zeros or by geometrical effects. A direct way of resolving this question is to change the interaction radius in a reaction, while keeping all other parameters fixed, and to see whether the dips move. The "radius" of a virtual spacelike photon has been predicted to change with its mass. If this is verified (e.g., in ρ^0 electroproduction), a study of the dip in π^0 electroproduction should decide between the two schools of dip mechanisms. (auth)

59347 IMPOSSIBILITY OF REDUCTION OF ELECTROMAGNETIC FIELDS IN FREE SPACE FOR NONZERO-MASS SYSTEM. Rajput, B. S. (Kurukshetra Univ., India). Lett. Nuovo Cim.; 2: No. 14, 712-14(2 Oct 1971).

It is shown that for nonzero-mass systems it is not possible to reduce the electromagnetic fields which satisfy Maxwell's equations without sources. The reduction is possible only either in the presence of charge-source or current-source or of both. (L.B.S.)

59348 RHO–OMEGA INTERFERENCE AND THE PHASE OF THE RHO-PROPAGATOR. Allcock, G. R.; Whipp, A. T. (Univ. of Liverpool). Lett. Nuovo Cim.; 2: No. 14, 719-23 (2 Oct 1971).

In order to reconcile recent observations of $\rho-\omega$ interference in the leptonic and hadronic decay modes from photoproduction processes, it is suggested that the pole in the ρ-propagator has a complex residue, that the residue is far from being real, and has a phase of about $-100°$. (L.B.S.)

59349 ON THE EXACT PROPAGATOR. Jones, A. V.; Papadopoulos, G. J. (Univ. of Leeds, Eng.). J. Phys., A (London); 4: No. 5, L86-9(Sep 1971).

The propagator is evaluated for an electron subject to a harmonic force, a constant magnetic field and a time prescribed electric field, exactly. However, the primary concern is to draw attention to important works in the literature that have been overlooked, a result of which has brought some duplication without always corresponding methodological improvement. (auth)

59350 ELECTROMAGNETIC WAVE TAILS IN THE SECOND APPROXIMATION TO THE EINSTEIN–MAXWELL EQUATIONS. Rotenberg, M. A. J. Phys., A (London); 4: No. 5, 617-31(Sep 1971).

With a finite oscillating linear coherent distribution of electric charge chosen as the source of electromagnetic radiation, it is shown that the outgoing multipole electromagnetic waves of the linear approximation to the Einstein–Maxwell equations produce wave tails in the second approximation which, after the end of the source vibration, constitute incoming multipole waves. (auth)

59351 VECTOR MESON DOMINANCE AND PION PHOTOPRODUCTION. Potter, Wendy Nan Torrance. Urbana, Ill.; Univ. of Illinois (1971). 110p. University Microfilms Order No. 71-21,214.

Thesis.

A detailed theoretical treatment is given of the vector meson dominance approximation of a k^2 dispersion relation for any of a large number of sets of invariant amplitudes for pion photoproduction. The resulting cross section always has a kinematic singularity; whether or not it is in the physical region depends on which set is used. The standard proportionality between polarized photon and vector meson cross sections in the center of mass is recovered at high s for some of the sets discussed. Support for vector meson pole dominance of a k^2 dispersion relation at high s is found from the investigation of the analyticity of the box graph as a function of the mass-squared of one of the external particles. A question is raised concerning the renormalization of divergent diagrams containing a single vector meson virtual state in the familiar Lagrangian treatment of vector meson dominance. (Diss. Abstr.)

59352 VENEZIANO-TYPE REPRESENTATIONS OF THE PION FORM FACTOR AND COUPLINGS OF PHOTONS TO HEAVY VECTOR MESONS. Cleymans, J.; Rodenberg, R. (Technische Hochschule, Aachen). Nuovo Cim.; 5A: No. 2, 297-304(21 Sep 1971).

Consequences of Veneziano-type representations for the pion form factor are considered. It is found that a simultaneous fit to the asymptotic behavior and to the couplings of photons to vector mesons is not possible without adding satellite terms. The smallness of the derived couplings of higher vector mesons is shown to be related to the small observed deviation from ρ universality. (auth)

59353 ELECTROPRODUCTION OF π^0-MESONS ON PROTONS IN THE BACKWARD DIRECTION. Driver, C. (DESY, Hamburg); Heinloth, K.; Hoehne, K.; (and others). Nucl. Phys.; B33: No. 1, 84-100(1971).

Electroproduction of π^0-mesons on protons at backward angles was investigated by measuring the scattered electron and the recoiling proton in coincidence. The differential cross section was determined as a function of W, q^2, $\theta_{\pi^0}^{cms}$ and u. (auth)

59354 WIDE ANGLE SCATTERING IN QUANTUM ELECTRODYNAMICS. Cardy, J. L. (Cambridge Univ., Eng.). Nucl. Phys.; B33: No. 1, 139-51(1971).

High energy elastic electron-electron scattering at wide angles is studied in quantum electrodynamics. The amplitude is predicted to decrease exponentially with increasing energy, in agreement with strong interaction data. (auth)

59355 ELECTROPRODUCTION OF PIONS ON NUCLEI IN BOUND STATES. Dmitriev, V. F. (Inst. of Nuclear Physics, Novosibirsk, USSR). JETP Lett. (USSR) (Engl. Transl.); 14: No. 2, 81-3(20 Jul 1971).

Translated from Zh. Eksp. Teor. Fiz., Pis'ma Red.; 14: No. 2, 124-7(20 Jul 1971).

An experimental study of electroproduction of a pion immediately in the bound state of a mesic atom is proposed to obtain information on the s-levels of mesic atoms with large Z. The cross section for this process is calculated for ^{12}C, ^{20}Ne, and ^{35}Cl. (L.B.S.)

59356 AXIAL-VECTOR FORM FACTORS FROM CURRENT ALGEBRA REGGE POLES AND VENEZIANO MODEL. Dominguez, C. A.; Zandron, O. (Univ., Buenos Aires). Nucl. Phys.; B33: No. 1, 303-16(1971).
